# Collier's Encyclopedia

COPERNICVS
DE REVOLUTIONIBUS

*THE THEME OF THE END PAPERS OF THIS VOLUME IS MAN'S MARCH THROUGH HISTORY. THE PANELS REPRESENT WHAT, IN OUR EDITORS' OPINIONS, WERE THE CRITICAL POINTS OF HIS PROGRESS. THEY ARE ARRANGED CHRONOLOGICALLY FROM LEFT TO RIGHT.*

The pronunciation system used in *Collier's Encyclopedia* is based on the International Phonetic Alphabet.

## PRONUNCIATION KEY

(*alphabetically arranged*)

| *Phonetic Symbol* | *Sound Represented* | *Phonetic Symbol* | *Sound Represented* |
|---|---|---|---|
| ɑ | f*a*ther, c*a*r | ŋ | si*ng*ing |
| ɑ̃ | (Fr.) él*an*, *en* | o | n*o*te, *o*ld |
| ɒ | wh*a*t, n*o*t | õ | (Fr.) b*on*, r*om*pre |
| a | *a*sk, *a*nswer; (Fr.) *a*ttacher | ö | (Ger.) schön, böse |
| æ | h*a*t, b*a*ck | ɔ | *o*rb, *a*ll |
| æ̃ | (Fr.) v*in*, m*ain* | œ | (Fr.) l*eu*r; (Ger.) können |
| ai | cr*y*, sp*i*ne | œ̃ | (Fr.) br*un*, l*un*di |
| au | pr*ow*, l*ou*d | ɔi | t*oy*, p*oi*nt |
| b | *b*o*b* | p | *p*ro*p* |
| d | *d*i*d* | r | *r*oa*r* |
| e | f*a*te, *e*lite | s | *s*auce |
| ɛ | y*e*t, sp*e*ll | sh | ha*sh*i*sh* |
| ə | mak*e*r, *a*go | t | *t*ro*t* |
| ɜ | f*i*rst, b*u*rn | th | *th*irty-*th*ree |
| f | *f*orfeit | th | o*th*er *th*an *th*is |
| g | *g*a*g* | u | r*u*le, pr*u*ne |
| h | *h*ot*h*ouse | ü | (Fr.) cr*u*; (Ger.) gr*ü*n |
| i | *e*ve, benz*i*ne | ʊ | b*u*ll, b*u*sh |
| ɪ | *i*f, st*i*ng | ʌ | b*u*t, s*o*n |
| j | *j*u*dg*e | v | *v*i*v*id |
| k | *c*a*k*e | w | *w*oo*dw*ork |
| χ | (Ger.) i*ch*, a*ch* | y | *y*este*ry*ear |
| l | *l*oya*l* | z | priz*e*s |

# CONTRIBUTORS TO VOLUME EIGHTEEN

**A.C. Americo Castro,** Ph.D.

Emory L. Ford Professor of Spanish, Princeton University.

**A.Cu. Alden Cutshall,** B.Ed., M.A., Ph.D.

Associate Professor of Geography, University of Illinois.

**A.C.B. A. Cornelius Benjamin,** A.B., A.M., Ph.D.

John H. Lathrop Professor of Philosophy, Chairman of the Department of Philosophy, University of Missouri.

**A.C.T. Alfred C. Tan,** B.A., (National Wuhan U., China), M.S., M.A.

Editor, Chinese News Service, New York, N.Y.

**A.D. Allison Danzig,** A.B.

Football, Tennis, and Rowing Editor, *The New York Times.*

**A.D.W. A. D. Wallace,** B.S., M.S., Ph.D.

Former Assistant Professor of Mathematics, University of Pennsylvania.

**A.E. Abraham Edel,** B.A., M.A., B.A. (Oxon.), Ph.D.

Assistant Professor of Philosophy, College of the City of New York.

**A.E.A. A. E. Alexander,** B.S., Ph.D.

Gem Expert, Tiffany & Co.; Consulting Ceramic Engineer, Electric Auto-Lite Co., Champion Spark Plug Co.

**A.E.R. Antony E. Raubitschek,** Ph.D. (U. of Vienna).

Associate Professor of Classics, Princeton University.

**A.E.W. Albert E. Wood,** B.S., M.A., Ph.D.

Associate Professor of Biology, Amherst College.

**A.F.B. Aline Frankau Bernstein**

Scenic and Costume Designer; President, Costume Institute, Metropolitan Museum of Art; Visiting Lecturer and Instructor, Drama Department, Vassar College.

**A.Gr. Albert Greenberg**

Member of the Staff, Everglades Aquatic Nurseries, Tampa, Fla.

**A.G.R. Albert G. Ramsperger,** Ph.D.

Professor of Philosophy, Chairman of the Department of Philosophy, University of Wisconsin.

**A.G.S. A. G. Shenstone,** B.A. (Cambridge U.), M.A., Ph.D.

Professor of Physics, Princeton University.

**A.G.Sm. Alfred G. Smith,** B.A., M.A.

Acting Instructor in Philosophy, University of Wisconsin.

**A.Ho. Arthur Hopkins**

Theatrical Producer.

**A.H.G. Anna H. Gayton,** A.B., M.A., Ph.D.

Professor of Decorative Art, Associate Curator of Textiles, Museum of Anthropology, University of California (Berkeley).

**A.H.Gr. Arthur Harmount Graves,** B.A., Ph.D.

Curator Emeritus, Brooklyn Botanic Garden; Consulting Pathologist, Connecticut Agricultural Experiment Station.

**A.H.L. Alfred H. Lovell,** M.S.E.

Professor of Electrical Engineering, Chairman of the Department of Electrical Engineering, University of Michigan.

**A.H.N. Arthur H. Nethercot,** M.A., Ph.D.

Professor of English Literature, Northwestern University.

**A.H.Sw. Alfred H. Sweet,** A.B., A.M., Ph.D.

Linn Professor of History, Washington and Jefferson College.

**A.J.Z. Arnold J. Zurcher,** A.B., M.A., Ph.D.

Professor of Political Science, Head of the Institute of Public Affairs and Regional Studies, New York University.

**A.L. Adrian Lambert,** M.D., F.A.C.S.

Associate Attending Surgeon, Nassau County Sanitarium; Assistant Director of Chest Surgery, Bellevue Hospital, New York, N. Y.; Instructor in Surgery, Columbia University.

**A.La. Arthur Ladu,** Ph.D.

Professor of English, North Carolina State College.

**A.L.H-Q. Alfred Lawrence Hall-Quest,** B.A., M.A., Ph.D.

Former Professor of General Education, New York University; Former Research Specialist in Adult Education, Carnegie Corporation.

**A.L.R. Allan L. Rodgers,** B.Sc., M.A., Ph.D.

Assistant Professor of Geography, Pennsylvania State College.

**A.M.-S. Alexander Mackay-Smith,** A.B. LL.B.

Farmer, Agricultural Consultant, North Wales Stud Farm, Warrenton, Va.; Vice-President, American Horse Shows Association.

**A.Pr. Albert Preisman,** A.B., E.E.

Vice-President in charge of Engineering, Capitol Radio Engineering Institute.

**A.Sv. Arthur Svihla,** A.B., M.S., Ph.D.

Professor of Zoology, University of Washington.

**A.S.M. Alfred S. Myers**

Free Lance Writer.

**A.TenE.G. Albert TenEyck Gardner**

Research Fellow, Office of the Director, Metropolitan Museum of Art.

**A.V. Amry Vandenbosch,** Ph.B., Ph.D.

Professor of Political Science, University of Kentucky; Advisory Editor, *Far Eastern Quarterly.*

**A.Wi. Albin Widen,** Fil.kand., Fil.lic. (U. of Stockholm).

Free Lance Writer, Sweden.

**A.W.Gr. Albert Woodruff Gray,** B.A., LL.B.

Free Lance Writer.

**A.W.S. Arthur W. Swann,** B.D., B.S. in L.S., A.M.L.S.

Librarian, Gammon Theological Seminary.

**A.W.Van B. A. W. Van Buren,** A.B., Ph.D.

Emeritus Professor of Archaeology, American Academy in Rome.

**B.B. Brand Blanshard,** B.A., M.A., B.Sc. (Oxon.), Ph.D.

Professor of Philosophy, Yale University.

**B.C.G. Barbara Crawford Glasrud,** B.A., M.A.

Former Senior Resident, Bryn Mawr College.

**B.G.C. Bernice Gertrude Chambers,** B.S., M.A.

Assistant Professor of Retailing, New York University.

**B.L. Bartholomeus Landheer,** Cand. Juris. (U. of Leyden), Ph.D. (U. of Vienna).

Visiting Professor of Sociology, University of Alabama; Former Head, Research Department, Netherlands Information Bureau, New York, N.Y.

**B.M.M. Rev. Bruce Manning Metzger,** A.B., Th.B., Th.M., A.M., Ph.D.

Associate Professor of New Testament, Princeton Theological Seminary; Member, Board of Managers, American Bible Society; Editorial Secretary, *Theology Today*.

**B.P. Brooks Palmer,** B.S.

Vice-President, National Association of Watch and Clock Collectors.

**B.Pr. Benfield Pressey,** A.B., A.M.

Professor of English, Dartmouth College.

**B.Ro. Benjamin Rowland, Jr.,** B.S., Ph.D.

Associate Professor of Fine Arts, Harvard University.

**B.Sm. Boyd Smith,** LL.B., M.A.

Professor of Drama, Chairman of the Department of Drama, Executive Officer, Division of the Arts, Yale University.

**B.S.H. B. Smith Hopkins,** A.B., A.M., Ph.D., D.Sc., LL.D.

Emeritus Professor of Chemistry, University of Illinois.

**B.V.C. Bartholow V. Crawford,** A.M., Ph.D.

Professor of English, University of Iowa.

**C.A.A. Rev. Charles A. Anderson,** A.B., B.D., M.A., D.D., LL.D.

Manager and Editor, *Journal,* Presbyterian Historical Society, Former President, Tusculum College and Coe College; Trustee, Westminster Foundation, Philadelphia, Pa.

**C.A.M. Clarence A. Manning,** A.B., A.M., Ph.D.

Assistant Professor of Slavic Languages, Columbia University.

**C.B.A. Carl B. Allendoerfer,** B.S., B.A. (Oxon.), M.A. (Oxon.), Ph.D.

Professor of Mathematics, Haverford College; Former Vice-President, Mathematical Association of America; Member, Institute for Advanced Study.

**C.B.B. Chandler B. Beall,** B.A., Ph.D.

Professor of Romance Languages, University of Oregon.

**C.B.F. C. Bruce Fergusson,** B.A., B.A. (Oxon.), M.A. (Oxon.).

Assistant Archivist, Public Archives of Nova Scotia; Lecturer in Contemporary History, Nova Scotia Technical College.

**C.B.M. C. Bradford Mitchell,** Ph.D.

Public Relations Officer, American Merchant Marine Institute; Editor, *Steamboat Bill of Facts;* Member of Editorial Advisory Board, *The American Neptune*.

**C.C.H. Colbert C. Held,** A.B., A.M.

Graduate Student, Graduate School of Geography, Clark University.

**C.C.Wh. Clyde C. Whipple,** B.S., E.E.

Professor of Electrical Engineering, Polytechnic Institute of Brooklyn.

**C.D. Charles Duffy,** Ph.B., M.A., Ph.D.

Pierce Professor of English, Chairman of the Department of English, University of Akron.

**C.DeB. Cornelius De Boe,** A.B., A.M., Th.B., Ph.D.

Professor of Philosophy and Christian Ethics, School of Theology, Temple University.

**C.E.K. Charles E. Kellogg,** Ph.D.

Chief, Division of Soil Survey, Head Soil Scientist, U.S. Department of Agriculture.

**C.E.M. Charles E. Mounts,** A.B.E., M.A., Ph.D.

Associate Professor of English, University of Florida.

**C.G.O. Charles G. Osgood,** B.A., Ph.D., Litt.D.

Emeritus Professor of English, Princeton University.

**C.H.Cu. C. H. Curran,** B.S. Agric., M.A., D.Sc.

Curator, Department of Insects and Spiders, American Museum of Natural History.

**C.H.Go. Cyrus H. Gordon,** A.B., M.A., Ph.D.

Professor of Assyriology and Egyptology, Dropsie College.

**C.H.Wo. Carol H. Woodward,** B.A.

Editor, *The Journal,* New York Botanical Garden.

**C.K.H. Charles K. Hallowell,** B.S.

County Agent, Philadelphia County, Pa.; Member, American Society of Agronomy.

**C.K.Hy. Clyde Kenneth Hyder,** Ph.D.

Professor of English, University of Kansas; Editor, University of Kansas Press.

**C.J.W. Carl J. Weber,** B.A., M.A. (Oxon.), Litt.D.

Roberts Professor of English Literature, Colby College.

**C.L.D. Chester L. Dawes,** S.B., A.M., Dr.Eng.

Associate Professor of Electrical Engineering, Harvard University.

**C.M.D. Christopher M. Dawson,** B.A., Ph.D.

Associate Professor of Greek, Yale University.

**C.P.P. Charles P. Parkhurst, Jr.,** A.B., M.A., M.F.A.

Assistant Professor of Art and Archaeology, Princeton University.

**C.Ro. Carl Rodman,** A.B., M.I.A.

Free Lance Writer.

**C.R.E. Chester R. Earle,** B.S.

Managing Editor, *Power Generation.*

**C.R.No. Charles R. Noback,** B.S., M.S., Ph.D.

Associate Professor of Anatomy, Long Island College of Medicine.

**C.R.S. Charles Robbins Schroeder,** B.S., D.V.M.

Assistant Director, Animal Industry Section, Lederle Laboratories Division, American Cyanamid Company; Former Veterinarian, New York Zoological Park.

**C.R.Sl. Charles R. Sleeth,** A.B., A.M., B.A. (Oxford U.), M.A., Ph.D.

Instructor in German, Department of Modern Languages and Literature, Princeton University.

**C.S.Sp. C. Sumner Spalding,** A.B., M.A., B.S.

Music Cataloger, Library of Congress.

**C.T.H. Charles T. Haven**

Former Technical Assistant, Johnson Automatics.

**C.T.M. Charles T. Murphy,** A.B., M.A., Ph.D.

Associate Professor of Classics, Head of the Department of Classics, Oberlin College.

**C.T.P. C. Terence Pihlblad,** M.A., Ph.D.

Professor of Sociology, Chairman of the Department of Sociology, University of Missouri.

**C.W.D. Caleb W. Davis,** A.B., A.M.

Free Lance Writer.

**C.W.F. Charles Warren Fox,** A.B., Ph.D.

Instructor in Musicology and Psychology, Eastman School of Music, University of Rochester.

**D.A.H. Darwin A. Hindman,** A.B., M.A., Ph.D.

Professor of Physical Education, Director of Student Affairs, University of Missouri.

**D.B. David Bidney,** B.A., M.A., Ph.D.

Research Assistant, Institute of Human Relations, Yale University and Peabody Museum; Research Associate in Anthropology, Viking Fund.

**D.Ch. Djang Chu,** A.B. (U. of Shanghai), M.A., Ph.D.

Special Lecturer, School of Advanced International Studies.

**D.D.M. Donald D. Millikin**

Former Major, United States Army; Former Free Lance and Technical Writer.

**DeL.F. DeLancey Ferguson,** B.A., M.A., Ph.D.

Professor of English, Chairman of the Department of English, Brooklyn College.

**D.F.P. Donald F. Putnam,** B.S.A., Ph.D. (U. of Toronto).

Associate Professor of Geography, University of Toronto.

**D.G. Rabbi David Graubart,** B.S., M.A., D.D., Ph.D.

Rabbi and President, The Bet Din (Ecclesiastical Court) of the Chicago Council of the United Synagogue of America; Lecturer in History, College of Jewish Studies.

**D.G.F. Donald G. Fink,** B.Sc., M.Sc.

Co-Director of Research, Philco Corporation.

**D.G.G.K. Donald G. G. Kerr,** B.A., Ph.D. (U. of London).

Professor of History, Mount Allison University.

**D.Ho. Dan Holland**

Former Managing Editor, *Field and Stream.*

**D.H.K.-A. David H. Kallner-Amiran,** Ph.D.

Member of the Staff, Department of Geography, The Hebrew University, Jerusalem, Israel.

**D.J.M.C. Daniel J. M. Callahan,** S.J., A.B., S.T.L.

Professor of Dogmatic Theology and Liturgics, Woodstock College.

**D.J.S. David J. Stump,** M.D.

Department of Surgical Pathology, Columbia University Medical School.

**D.L. Donna Lapinskas,** A.B., A.M.

Instructor in Geography, New Jersey State Teachers College.

**D.L.E. Donald L. Engle,** B. Mus., B.S., M.A.

Press Representative and Program Annotator, The Philadelphia Orchestra.

**D.M.S. Dorothy M. Schullian,** A.B., Ph.D., F.A.A.R.

Curator of Rare Books, Army Medical Library, Armed Service Forces.

**D.N.R. David N. Rowe,** A.B., A.M., Ph.D.

Professor of Political Science, Yale University.

**D.N.W. Donald N. Wilbur,** A.B., M.F.A. in Arch.

Associate Professor of Classical Studies, The Asia Institute.

**D.R. Dana Rush**

Free Lance Writer; Former Staff Writer, *Current Biography.*

**E.A.R. Edward A. Ryan,** S.J., A.B., S.T.L.

Professor of Church History, Woodstock College.

**E.B.A. Elsie B. Allen**

Free Lance Writer.

**E.B.B. Edwin B. Boldrey,** A.B., M.A., M.D., M.Sc.

Associate Professor of Neurological Surgery, University of California Medical School; Attending Neurological Surgeon, University of California Hospital.

**E.B.S. Eleanor B. Swenson,** A.B.

Associate Curator, Corcoran Gallery of Art.

**E.C.R. Edward C. Raney,** B.S., M.S., Ph.D.

Associate Professor of Zoology and Fishery Biology, Cornell University; Secretary, American Society of Ichthyologists and Herpetologists.

**E.C.Ro. Emeline C. Roche**

Costume and Scenic Designer and Technician for Broadway Productions.

**E.C.S. Erwin C. Stumm,** A.B., A.M., Ph.D.

Assistant Professor of Geology, Associate Curator of the Museum of Paleontology, University of Michigan; Former Member, U.S. Geological Survey.

**E.C.Sh. Emerson C. Shuck,** B.S., M.A., Ph.D.

Professor of English, Director of the Graduate School, Bowling Green State University.

**E.D.H. Everett D. Howe,** B.S., M.S.

Professor and Associate Dean of Engineering, University of California.

**E.E.B. Elizabeth E. Bacon,** B.A., Ph.D.

Lecturer in Anthropology, University of California; Former Research Analyst, Iran and Afghanistan, U.S. Department of State.

**E.E.E. Edward E. Edwards,** B.S., M.S.

Professor of Finance, Indiana University; Secretary-Treasurer, American Finance Association.

**E.F. Ernst Feise,** Ph.D. (U. of Leipzig).

Professor of German, Johns Hopkins University; Former Director, School of German, Middlebury College.

**E.Fr. Eleanor Frankle,** M.A., Ph.D.

Former Translator of Russian Linguistic Materials, Basque Delegation.

**E.F.D. Edward F. Dow,** B.S., M.A., Ph.D.

Professor of Government, Head of the Department of History and Government, University of Maine.

**E.H.Co. Edward H. Cox,** A.M., D.Sc.

Professor of Chemistry, Chairman of the Department of Chemistry, Swarthmore College.

**E.H.Z. Edwin H. Zeydel,** A.B., A.M., Ph.D.

Professor of German, Head of the Department of German, University of Cincinnati.

**E.J.B. Edward J. Brown**

Free Lance Writer.

**E.J.C.K.deJ. E. J. C. Kiewiet de Jonge,** B.A., M.A.

Graduate Student, Graduate School of Geography, Clark University; Former Officer, K.N.I.L. (Royal Netherlands Indies Army).

**E.J.J. Edward J. Jurji,** B.A., M.A., Ph.D., Th.B.

Associate Professor of Islamics and Comparative Religion, Princeton Theological Seminary; Lecturer in Oriental Languages, Princeton University.

**E.L.A. Emmett L. Avery,** A.B., A.M., Ph.D.

Professor of English, State College of Washington.

**E.L.F. E. Lee Fairley,** B.M., M.M.

Music Specialist, U.S. Department of State; Associate Editor, *Notes,* Music Library Association; Program Annotator, National Symphony Orchestra.

**E.L.Sh. Estelle L. Sharp**

Garden Consultant, Berwyn, Pa.

**E.M.F. Ernest M. Fernald,** M.E., M.M.E.

Professor of Mechanical Engineering, Lafayette College.

**E.Na. Elemer Nagy,** Dr. of Pol. Sci. (U. of Francesco Josephina, Hungary).

Chairman, Department of Drama, The Julius Hartt School of Music; Opera Director and Designer, Central City Opera Association.

**E.O.B. Edmund Olaf Belsheim,** B.A., B.A. in Juris. (Oxon.), B.C.L. (Oxon.), J.S.D.

Professor of Law, University of Nebraska; Director, Lincoln Legal Aid Bureau, Lincoln, Neb.

**E.P.W. Estellene P. Walker**

Executive Secretary, South Carolina State Library Board.

**E.R.A. E. R. Adair,** B.A., B.A. (Cambridge U.), M.A. (Cambridge U.).

Professor of History, McGill University; Former President, Canadian Historical Association.

**E.R.C. Emily Read Cheston**

Garden Consultant; Lecturer on Horticultural Subjects.

**E.R.H. Elizabeth Reynolds Hapgood,** Dipl. (École des Hautes Études).

Instructor in Russian, Evening Session, Hunter College.

**E.St. Elvyn Stoneman,** B.A., M.A.

Instructor in Geography, Indiana University.

**E.S.B. Edgar Sheffield Brightman,** A.B., A.M., S.T.B., Ph.D., Litt.D., LL.D.

Borden Parker Bowne Professor of Philosophy, Boston University; Permanent Chairman, Board of the Graduate School, Brown University.

**E.T. Eric Thomsen**

Assistant Professor of Mechanical Engineering, University of California.

**E.T.C. Rev. Elmer T. Clark,** A.B., B.D., S.T.D., LL.D., Litt.D.

Editor, *World Outlook;* Editorial Secretary, Board of Missions and Church Extension, The Methodist Church.

**E.W. Edmund Whittaker,** B.Sc., Ph.D. (U. of Edinburgh).

Professor of Economics, Colorado Agricultural and Mechanical College.

**E.W.H. Everett W. Hall,** A.B., A.M., Ph.D.

Professor of Philosophy, Head of the Department of Philosophy, State University of Iowa.

**F.A.C. Fenner A. Chace, Jr.,** A.B., A.M., Ph.D.

Curator of Marine Invertebrates, U.S. National Museum.

**F.A.F. Francis A. Fahey,** S.J., A.B., S.T.L.

Professor of Classics, Fordham Preparatory School.

**F.A.K. Forrest A. Kingsbury,** M.A., Ph.D.

Visiting Professor of Psychology, Redlands University; Emeritus Professor of Psychology, University of Chicago.

**F.B.E. Frank B. Evans, III,** A.B., M.A., Ph.D.

Assistant Professor of English, College of William and Mary.

**F.B.F. Frederic Brenton Fitch,** B.A., Ph.D.

Associate Professor of Philosophy, Yale University.

**F.B.L. F. Bradley Lynch,** A.B.

Public Relations, The Firestone Tire and Rubber Company.

**F.B.T. Frederick B. Tolles,** Ph.D.

Assistant Professor of History, Librarian of Friends Historical Library, Swarthmore College.

**F.C.C. Frank C. Campbell**

Member, Circulation Department, *Notes,* Quarterly Jounal of the Music Library Association.

**F.C.H. Fred C. Hamil,** B.A., M.A., Ph.D.

Assistant Professor of History, Wayne University.

**F.C.W. Francis Carter Wood,** B.S., M.D.

Emeritus Director of Cancer Research, Columbia University.

**F.Go. Frederick Goldberg,** B.A.

Free Lance Writer.

**F.G.P. Franklyn George Palmer,** B.A.

Free Lance Writer.

**F.J.R. Frank J. Roos, Jr.,** Ph.B., Ph.D.

Professor of Art, University of Illinois.

**F.J.S. Fred Jay Seaver,** B.S., Ph.D., Sc.D.

Curator, New York Botanical Garden.

**F.J.W. Fergus J. Wood,** A.B., PhD.

Assistant Professor of Physics, University of Maryland.

**F.-K.L. Frang-Kuei Li,** A.B., M.A., Ph.D.

Visiting Professor of Chinese, Yale University; Member, Academia Sinica, China.

**F.L.L. F. L. Lucas,** M.A. (Cambridge U.).

Reader in English Literature, Cambridge University; Fellow of Kings College, Cambridge.

**F.M. Fritz Mezger,** Ph.D.

Professor of Germanic Philology, Bryn Mawr College.

**F.Mo. Frederick Mosteller,** B.Sc., M.Sc., A.M., Ph.D.

Associate Professor of Mathematical Statistics, Harvard University.

**F.P.Ma. Frank Pelletreau Mathews,** A.B., M.D.

Former Assistant Clinical Professor of Public Health, Yale University; Physician, Memorial Clinic, Olympia, Washington.

**F.R.F. F. Raymond Fosberg,** A.B., M.Sc., Ph.D.

Professorial Lecturer in Botany, George Washington University; Research Associate, Department of Biology, Catholic University of America.

**F.R.T. Frederick R. Thompson,** B.A., M.D., Sc.D.

Assistant Orthopedic Surgeon, St. Luke's Hospital; Chief Attending Orthopedic Surgeon, Manhattan State Hospital, New York, N.Y.

**F.S. Frederick Seitz,** A.B., Ph.D.

Professor of Physics, Head of the Department of Physics, Carnegie Institute of Technology.

**F.Sc. Francis Schadegg,** A.B., M.A.

Graduate Student, Graduate School of Geography, Clark University.

**F.V. Fernand Vial,** Bac.-ès-Lettres (U. of Aix-en-Provence), M.A., Ph.D.

Associate Professor of French, Chairman of the Department of Romance Languages, Fordham University.

**F.V.C. Fred V. Cahill, Jr.,** B.A., M.A., Ph.D.

Assistant Professor of Political Science, Yale University.

**F.Wi. Frank Wills,** B.S.

Former Production Engineer, Gas Department, Pacific Gas and Electric Co.

**F.W.W. F. W. Went,** A.B., M.A., Ph.D.

Professor of Plant Physiology, California Institute of Technology.

**G.A.H. George A. Hindes,** D.D.S.

Dental Surgeon; Former Member, Dental Department, New York City Hospitals.

**G.B. Giuliano Bonfante,** Ph.D. (U. of Rome).

Professor of Romance Languages, Princeton University.

**G.B.S. George Brandon Saul,** A.B., A.M., Ph.D.

Professor of English, University of Connecticut.

**G.C. Gilbert Chase**

Associate Librarian, Music Division, Library of Congress.

**G.C.K. Grant C. Knight,** A.B., A.M.

Professor of American Literature, University of Kentucky.

**G.D. Gibson Danes,** B.F.A., B.S., M.A., Ph.D.

Associate Professor of Art, School of Fine Arts, Ohio State University.

**G.E.D. George E. Duckworth,** A.B., M.A., Ph.D.

Giger Professor of Classics, Princeton University.

**G.E.L. Georges E. Lemaitre,** B.A. (Algiers), Agrégé de l'Université, D.ès L. (U. of Paris).

Professor of French, Stanford University.

**G.E.M. George E. Mowry,** Ph.D.

Professor of American History, State University of Iowa.

**G.G.C. Gustav G. Carlson,** A.B., M.A., Ph.D.

Associate Professor of Anthropology and Sociology, University of Cincinnati.

**G.G.E. George Grant Elmslie**

Architect; Former Assistant in Design and Plan to Louis Henry Sullivan.

**G.G.F. George Gillespie Fox,** A.B., Ph.D.

Head Professor of Philosophy, Former Professor of English, University of Florida.

**G.H.Cl. Gordon H. Clark,** Ph.D.

Associate Professor of Philosophy, Butler University.

**G.H.H. George Heard Hamilton,** Ph.D.

Associate Professor of History of Art, Yale University; Curator of the Collection Société Anonyme and of the Edwin Austin Abbey Collection, Yale University Art Gallery.

**G.H.K. George Harmon Knoles,** A.B., M.A., Ph.D.

Associate Professor of History, Stanford University.

**G.L.D.V. G. L. Della Vida,** Ph.D. (U. of Rome).

Professor of Arabic, Graduate School of Arts and Sciences, University of Pennsylvania.

**G.M.C. G. Miles Conrad,** B.A., M.A.

Editor, Graphic Science Associates, Inc.; Former Assistant Curator, Comparative and Human Anatomy, American Museum of Natural History.

**G.McL.H. George McLean Harper, Jr.,** B.A., M.A., Ph.D.

Garfield Professor of Ancient Languages, Chairman of the Department of Classics, Williams College.

**G.M.Sm. Gertrude M. Smith**

Garden Consultant, Montclair, N.J.

**G.N.A. George N. Adams**

Chief Taxidermist, American Museum of Natural History.

**G.N.P. Guy N. Parmenter,** B.A., M.A.

Geographer, Department of the Army.

**G.R.N. George Rapall Noyes,** A.B., A.M., Ph.D., Litt.D., LL.D.

Emeritus Professor of Slavic Languages, University of California.

**G.R.S. Gordon R. Silber,** A.B., Ph.D.

Professor of French and Italian, Chairman of the Department of Modern Languages, Union College.

**G.R.W. Gordon R. Willey,** B.A., M.A., Ph.D.

Anthropologist, Bureau of American Ethnology, Smithsonian Institution; Member, Institute of Andean Research.

**G.S. Goldwin Smith,** B.A., M.A., Ph.D.

Associate Professor of History, Wayne University.

**G.T. Griffith Taylor,** B.S., B.M.E., Sc.D. (U. of Sydney), A.B. (Cambridge U.).

Professor of Geography, Head of the Department of Geography, University of Toronto.

**G.W.L. Gerald W. Lattin,** B.S., M.S., Ph.D.

Professor of Hotel Administration, Cornell University; Formerly Personnel Consultant, Chalfonte-Haddon Hall and Metropolitan Museum of Art (Restaurant Project).

**G.W.R. Rev. George W. Richards,** A.B., A.M., D.D., LL.D., D.Th., (U. of Heidelberg).

Former President of Alliance of Reformed Churches Throughout the World Holding the Presbyterian System.

**G.W.S. George Winston Smith,** A.B., M.A., Ph.D.

Assistant Professor of History, Division of General Studies, University of Illinois.

**G.W.Sp. George W. Spicer,** B.A., Ph.D.

Professor of Political Science, University of Virginia.

**G.W.V.N. George W. Vander Noot**

Assistant Animal Husbandman, Department of Animal Husbandry, New Jersey Agricultural Experiment Station, Rutgers University.

**H.A.Br. Harold Anson Bruce**

Head Coach of Track, Field, and Cross Country, Varsity Indoor and Outdoor Teams, Tutor, College of the City of New York.

**H.A.J. Harold A. Johnson,** B.S., M.S.

Associate Professor of Mechanical Engineering, University of California.

**H.Bl. Rabbi Herbert Bloom,** B.A., M.H.L., Ph.D.

Rabbi, Temple Emanuel, Kingston, N.Y.; Jewish Chaplain, Wallkill Prison, New York.

**H.Bn. Harold Buschman,** A.B., B.D., Ph.D., S.T.M.

Professor of Philosophy, University of Kansas City.

**H.Bo. Harry Bouchard,** B.C.E.

Professor of Geodesy and Surveying; Director, Camp Davis, University of Michigan.

**H.Bol. Herbert Boland,** A.B.

Free Lance Writer.

**H.B.C. Herman B. Chubb,** A.B., M.A.

Professor of Political Science, University of Kansas.

**H.B.W. H. Bunker Wright,** A.B., M.A., Ph.D.

Associate Professor of English, Miami University; Lecturer in English, University of Cincinnati.

**H.Cow. Henry Cowell**

Lecturer in Music, Columbia University; Lecturer, New School for Social Research; Former Music Editor, Radio Division, Office of War Information.

**H.C.K. Hilmar C. Krueger,** Ph.D.

Associate Professor of History, University of Cincinnati.

**H.Dr. Herbert Drennon,** A.B., A.M., Ph.D.

Dean, Mississippi State College.

**H.E.M. Harry Estill Moore,** B.J., M.A., Ph.D.

Associate Professor of Sociology, University of Texas.

**H.E.W. Harold Everett Wessman,** B.S., M.S., C.E., Ph.D.

Dean, College of Engineering, University of Washington.

**H.F.M. Henri F. Muller,** Ph.D.

Former Professor of Romance Philology, Columbia University.

**H.Fu. Holden Furber,** A.B., B.A. (Oxon.), M.A. (Oxon.), Ph.D.

Associate Professor of History, University of Pennsylvania.

**H.G.De. Herbert G. Deignan,** B.A.

Associate Curator, Birds, U.S. National Museum.

**H.G.T. Harvey Gates Townsend,** A.B., Ph.D.

Former Professor of Philosophy, University of Oregon.

**H.Hr. Harlan Hatcher,** A.B., A.M., Ph.D., Litt.D., LL.D.

Professor of English, Vice-President, Ohio State University.

**H.H.D.** **Homer H. Dubs,** Ph.D., M.A. (Oxford U.)

Professor of Chinese, Oxford University.

**H.H.W.** **Hyatt Howe Waggoner,** A.B., A.M., Ph.D.

Associate Professor of American Literature, University of Kansas City.

**H.H.Wa.** **Harold H. Watts,** M.A., Ph.D.

Professor of English, Purdue University.

**H.J.R.** **H. J. Retallich,** B.A., M.A.

Graduate Student, Graduate School of Geography, Clark University.

**H.J.W.** **Henry J. Warman,** B.A., M.A., Ph.D.

Associate Professor of Geography, Secretary, Graduate School of Geography, Clark University.

**H.L.B.** **Henri L. Brugmans,** Lic. ès L., D. de l'U. de Paris, Elève Titulaire.

Associate Professor of French, Acting Chairman of the Department of Languages, Hofstra College.

**H.L.C.** **Howard Lester Cooke, Jr.,** A.B.

Resident Critic in the Department of Art and Archaeology, Princeton University.

**H.L.Cr.** **Harley L. Crane,** B.S. Agric., M.S., Ph.D.

Principal Horticulturist, U.S. Department of Agriculture.

**H.L.L.** **Harley L. Lutz,** A.B., A.M., Ph.D., LL.D.

Tax Consultant, National Association of Manufacturers; Former Professor of Public Finance, Princeton University.

**H.L.Sh.** **Harry L. Shapiro,** A.B., A.M., Ph.D.

Chairman, Department of Anthropology and Curator of Physical Anthropology, American Museum of Natural History; Professor of Anthropology, Columbia University.

**H.M.J.** **Howard Mumford Jones,** B.A., M.A., Litt.D., L.H.D.

Professor of English, Harvard University; President, American Academy of Arts and Sciences.

**H.M.M.** **Henry Miller Madden,** A.B., Ph.D.

International Refugee Organization, Linz, Austria.

**H.M.V.** **Harold M. Vinacke,** A.B., Ph.D.

Professor of International Law and Politics, University of Cincinnati.

**H.N.A.** **Hubert N. Alyea,** A.B., A.M., Ph.D.

Associate Professor of Chemistry, Princeton University.

**H.Pe.** **Henry Pettit,** B.A., M.A., Ph.D.

Professor of English, University of Colorado; Associate Editor, *Annual Bibliography of English Language and Literature.*

**H.R.N.** **H. R. Nayer,** A.B., M.D.

Diplomate, American Board of Internal Medicine; Associate, American College of Physicians.

**H.R.W.** **Harold R. Walley,** A.B., M.A., Ph.D.

Professor of English, Ohio State University.

**H.S.** **Herbert Sewell**

Director, Toledo Public Library.

**H.Sc.** **Harold Schlosberg,** A.B., M.A., Ph.D.

Professor of Psychology, Brown University.

**H.Sh.** **Harold Shadick,** B.A., M.A.

Professor of Chinese Literature, Cornell University.

**H.Si.** **Harry Silver**

Member, New York State Bar.

**H.S.R.** **High S. Rice,** B.S., A.M., Ph.D.

Research Associate, Hayden Planetarium, American Museum of Natural History.

**H.S.S.** **Herbert S. Schell,** A.B., M.A., Ph.D.

Professor of American History, Director of the Graduate School, University of South Dakota.

**H.S.T.** **Hugh S. Taylor,** B.Sc., M.Sc., D.Sc., LL.D.

David P. Jones Professor of Chemistry, Chairman of the Chemistry Department, Dean of the Graduate School, Princeton University.

**H.T.** **Harry Tschopik, Jr.,** A.B., M.A.

Assistant Curator of Ethnology, American Museum of Natural History.

**H.W.E.** **Harold W. Evans,** M.E.

Chief of the Tank and Automotive Branch, Ordnance Research and Development Division, Office of the Chief of Ordnance, U.S. Department of the Army.

**H.W.I.** **Harold Walter Iverson,** B.S. in M.E., M.S. in M.E.

Assistant Professor of Mechanical Engineering, University of California.

**H.W.L.** **Harry W. Laidler,** A.B., LL.B., Ph.D., A.M. (hon.).

Executive Director, League for Industrial Democracy; President and Director of the National Bureau of Economic Research; Member, Public Affairs Committee.

**H.W.Ri.** **Harold W. Richardson,** B.E. in C.E., C.E.

Editor, *Construction Methods.*

**I.B.** **Irene Behrens,** B.A., M.A.

Teacher, New York City Board of Education.

**I.S.S.** **Ivan S. Sokolnikoff,** B.S., in E.E., Ph.D.

Professor of Mathematics, University of California.

**J.A.Bo.** **John A. Borneman, Jr.**

Associate Professor of Homeopathic Pharmacy, Hahnemann Medical College.

**J.A.Br.** **James Arnold Brussel,** B.S., M.D. (Assoc.), A.C.P.

Assistant Director, Willard State Hospital, Willard, N.Y.; Former Chief Neuropsychiatric Consultant, Sampson Veterans Administration Hospital, New York.

**J.A.F.** **John A. Fleming,** B.S., D.Sc.

Adviser in International Scientific Relations, Carnegie Institution of Washington, D.C.; Former Director, Department of Terrestrial Magnetism, Carnegie Institution of Washington, D.C.

**J.-A.G.** **Jan-Albert Goris,** D.H.S.

Commissioner of Information for Belgium in the Western Hemisphere; Former Professor of Economic History, University of Louvain.

**J.A.L.M.** **Juan A. L. Marichal,** B.A., M.A., Ph.D.

Assistant Professor of Romance Literature, Harvard University.

**J.A.Sl.** **Joseph A. Slattery,** S.J., A.B., S.T.L.

Professor of English Literature, Woodstock College.

**J.C.Ma.** **J. Clyde Marquis,** B.S.A., M.S.A., D.A.

Advisor, Foreign Agricultural Relations, U.S. Department of Agriculture; Secretary, World Agriculture Society.

**J.C.S.** **Joseph C. Sloane,** M.F.A.

Associate Professor of History of Art, Chairman of the Department of History of Art, Bryn Mawr College.

**J.C.Wi.** **J. Christy Wilson,** A.B., M.A., Th.M., D.D.

Director of Field Work and Associate Professor in Ecumenics, Princeton Theological Seminary; Former Missionary in Iran.

**J.C.Wis.** **John C. Wister,** A.B., D.Sc.

Director, Arthur Hoyt Scott Horticultural Foundation, Swarthmore College; Director, John T. Tyler Arboretum, Lima, Pa.

**J.D.S.** **John Duncan Spaeth,** B.A., Ph.D. (U. of Leipzig), Litt.D., LL.D.

Emeritus President, University of Kansas City.

**J.E.F.** **Johnson E. Fairchild,** B.A.,M.A.

Professor of Social Philosophy, Head of the Division of Social Philosophy, Cooper Union; Former Assistant Dean in Charge of Veterans Session, Former Instructor in Geography, Hunter College.

**J.E.H.** **John E. Hankins,** A.B., A.M., Ph.D.

Professor of English, University of Kansas.

**J.E.Hi.** **John Eric Hill,** A.B., Ph.D.

Former Assistant Curator of Mammals, American Museum of Natural History.

**J.E.V.** **James E. Vance, Jr.,** A.B.

Graduate Student, Graduate School of Geography, Clark University.

**J.F.** **Rev. Jack Finegan,** B.A., M.A., B.D., M.Th., L.Th. (U. of Berlin).

Professor and Head of the Department of Old Testament and New Testament Literature and Interpretation, Director of the Palestine Institute of Archaeology, Dean of the Summer Session, Pacific School of Religion.

**J.F.M.** **James F. Mason,** A.B., Ph.D.

Emeritus Professor of Romance Languages and Literatures, Cornell University.

**J.F.McM.** **John Frederick McMahon,** A.B., M.A.

Associate Professor of German, Lawrence College.

**J.F.R.** **John Fraser Ramsey,** M.A., Ph.D.

Professor of European History, University of Alabama.

**J.Ga.** **John Gassner,** B.A., M.A.

Chairman, Play Department, Dramatic Workshop of the New School for Social Research; Lecturer in Dramatic Arts, Columbia University.

**J.G.D.C.** **J. Grahame D. Clark,** B.A., M.A., Ph.D. (Cambridge U.).

University Lecturer in Archaeology, Cambridge University; Editor, *Proceedings of the Prehistoric Society.*

**J.H.E.F.** **John H. E. Fried,** Ph.D., LL.D.

Lecturer on Government, Graduate School of Arts and Sciences, New York University.

**J.H.P.** **J. Hugh Pruett,** A.B, L.H.D.

Director, Astronomical Observatory, University of Oregon.

**J.H.W.** **John Hazard Wildman,** A.M., Ph.D.

Professor of English, Louisiana State University.

**J.H.Y.** **John Howard Young,** A.B., A.M., Ph.D.

Assistant Professor, Department of Classics, Johns Hopkins University.

**J.J.C.** **John J. Conley,** M.D.

Chief of Head and Neck Surgery, Pack Medical Group; Consultant Plastic Surgeon, Patterson General Hospital; Assistant Surgeon, Manhattan Eye and Ear Hospital.

**J.J.P.** **Julian J. Petty,** B.S., M.A., Ph.D.

Professor of Geography, University of South Carolina.

**J.J.T.** **James J. Talman,** B.A., M.A., Ph.D.

Chief Librarian, Associate Professor of History, University of Western Ontario.

**J.J.VanN.** **John James Van Nostrand,** A.B., M.A., Ph.D., LL.D.

Professor of Ancient History, University of California.

**J.K.D.** **J. K. Dale,** Ph.D.

Member of the Staff, Commercial Solvents Corporation.

**J.L.C.** **John L. Caskey,** B.A., Ph.D.

Assistant Professor of Classics, University of Cincinnati; Assistant Director, American School of Classical Studies at Athens (1948-1949).

**J.L.K.** **John L. Kind,** A.B., A.M., Ph.D.

Professor of Germanic Languages, Chairman of the Department of Germanic Languages, University of Tennessee.

**J.Me.** **Jerome Mellquist,** A.B.

Art Lecturer, New York University.

**J.M.B.** **John Morton Barnaby,** A.B.

Coach, Tennis and Squash Racquets, Harvard College.

**J.M.Ba.** **J. Murray Barbour,** A.B., M.A., Mus. Bac., Ph.D., Mus. Doc.

Associate Professor of Music, Michigan State College.

**J.M.H.** **Josephine M. Harris,** A.B., M.A., Ph.D.

Associate Professor of Art, Chairman of the Department of Fine Arts, Wilson College.

**J.M.St. J. M. Stockard**

Member, Bureau of Ordnance, Department of the Navy, Washington, D.C.

**J.P.H. J. Penrose Harland,** A.B., A.M., Ph.D.

Professor of Archaeology, University of North Carolina.

**J.P.Wo. James Playsted Wood,** A.B., M.A.

Head of Research Library, The Curtis Publishing Co.; Former Assistant Professor of English, Amherst College.

**J.R.To. Joseph Richard Toven,** A.B., A.M., Ph.D.

Assistant Supervisor of University Admissions, Assistant Professor of Spanish, New York University.

**J.Se. Janet Searles,** M.A.

Free Lance Writer in the field of Chemistry.

**J.S.F. James Street Fulton,** Ph.D.

Professor of Philosophy, The Rice Institute.

**J.S.Ma. Jane S. Mayer,** B.A.

Free Lance Writer.

**J.S.P. James S. Perkins**

National President, The Theosophical Society in America.

**J.S.R. Joseph S. Roucek,** B.A., M.A., Ph.D.

Professor of Political Science and Sociology, Chairman of the Department of Political Science and Sociology, University of Bridgeport.

**J.T.W. James T. Wilson,** A.B., Ph.D.

Assistant Professor of Geology, University of Michigan.

**J.W.L. James W. Leonard,** B.S., M.S., D.B.A.

Assistant Professor of Economics, University of Illinois.

**J.W.S. John W. Shive,** Ph.B., A.M., Ph.D.

Professor of Plant Physiology, Rutgers University.

**K.B. Klaus Berger,** Ph.D.

Assistant Professor of Art, University of Kansas City.

**K.G. Karl Geiringer,** Ph.D. (U. of Vienna).

Professor of History and Theory of Music, College of Music, Boston University.

**K.-H.P. Karl-Heinz Planitz,** A.B., M.A., Ph.D.

Assistant Professor of German, Temple University.

**K.K.L. Kenneth K. Landes,** B.S., A.M., Ph.D.

Professor of Geology, Chairman of the Department of Geology, University of Michigan.

**K.M.D. Karl M. Dallenbach,** A.B., M.A., Ph.D.

Distinguished Professor of Psychology, University of Texas.

**L.A.C. Lyman A. Cotten,** Ph.D.

Assistant Professor of English, University of North Carolina.

**L.A.V. Louis A. Vaczek**

Member, Foreign Service of Hungary; Instructor in Hungarian Language and Literature, Graduate School, Columbia University.

**L.Ba. Lydia Baer,** A.B., M.A., Ph.D.

Assistant Professor of German, Chairman of the Department of German, Swarthmore College.

**L.Bu. Leonard Burkat**

Librarian, Berkshire Music Center; Former First Assistant, Music Department, Boston Public Library.

**L.C.L. Rev. Leicester Crosby Lewis,** A.B., A.M., B.D., Ph.D., S.T.D., D.C.L.

Vicar, St. Luke's Chapel, Trinity Parish, New York, N.Y.; Former Professor of Church History, Philadelphia Divinity School.

**L.C.S. Louis Charles Schroeder,** B.P.E., M.P.E., M.A.

Director of Recreation, Recreation and Welfare Department, Oak Ridge, Tenn.

**L.de F. Lockwood de Forest**

Member, American Society of Landscape Architects; Former Professor, Santa Barbara State College; Former Editor, *Santa Barbara Gardener.*

**L.E.W. L. E. Wells**

Chief Engineer, Willard Storage Battery Co.

**L.F.D. Leonard F. Dean,** A.B., M.A., Ph.D.

Professor of English, University of Connecticut.

**L.G.R. L. G. Reeds,** M.A.

Special Lecturer in Geography, University of Toronto.

**L.H.Hy. Libbie H. Hyman,** Ph.D., Sc.D.

Research Associate (honorary), American Museum of Natural History.

**L.I.St. Leonid I. Strakhovsky,** B.Litt. (Alexander Lyceum), D.Hist. (U. of Louvain).

Former Lecturer in Slavic, Harvard University; Former Professor of European History, University of Maryland.

**L.J.O. Laurence J. O'Toole**

Director, Bureau of Municipal Research, Syracuse.

**L.J.W. Leo J. Wollemborg,** Ph.D.Litt., Ph.D.Law.

Associate Editor, *Economic News from Italy;* U.S. Correspondent for *Il Messaggero,* Rome, Italy.

**L.L. Lewis Leary,** B.S., A.M., Ph.D.

Associate Professor of American Literature, Duke University.

**L.M.A. Lewis M. Alexander,** B.A., M.A., Ph.D.

Instructor in Geography, Hunter College.

**L.N.R. Louis N. Ridenour,** B.S., Ph.D.

Professor of Physics, Dean of the Graduate College, University of Illinois.

**L.R. Lincoln Rothschild,** A.B., A.M.

Assistant Professor of Art, Chairman of the Department of Art, Adelphi College; Lecturer on the History of Art, Art Students League of New York.

**L.R.R. Leland Rex Robinson,** A.B., Ph.D.

Adjunct Professor, Political Economy, Graduate School of Business Administration, New York University.

**L.St. Lionel Stevenson,** B.A., M.A., Ph.D., B.Litt. (Oxon.).

Professor of English, Head of the Department of English, University of Southern California.

**L.T.R.** **Laurence T. Rogers,** A.B., M.A., Ph.D.

Professor of Health Education, George Peabody College.

**M.A.G.** **Rabbi Morris A. Gutstein,** B.S., Ph.D., D.H.L.

Rabbi, Congregation Shaare Tikvoh, Chicago, Ill.; Lecturer in American-Jewish History, College of Jewish Studies.

**M.Br.** **Manuel Brussaly,** B.A., M.A., Ph.D.

Assistant Professor of Romance Languages, New York University.

**M.Bu.** **Morris Buck,** M.E., E.E.

Transportation Consultant.

**M.B.H.** **Mohamed B. Hifny,** B.A., M.A.

Instructor, Geography Department, Faculty of Arts, Fouad I University, El Giza, Egypt.

**M.C.** **Margot Cutter,** A.B., M.A.

Fine Arts Editor, Princeton University Press; Managing Editor, *The Art Bulletin.*

**M.Co.** **Milton Comanor,** B.Ch.E., M.Ch.E.

Tutor in Physics, College of the City of New York; Former Engineer, Polytechnic Research and Development Corporation.

**M.C.Be.** **Monroe C. Beardsley,** Ph.D.

Assistant Professor of Philosophy, Swarthmore College.

**M.C.C.** **Mary C. Crosley,** B.A.

Free Lance Writer; Former Instructor in English, Pittsburgh Public Schools.

**M.E.** **Mark Eccles,** B.A., M.A., Ph.D.

Lecturer and Professor of English, University of Wisconsin.

**M.G.N.** **M. Graham Netting,** B.S., M.A.

Curator of Herpetology, Assistant Director, Carnegie Museum; Assistant Professor of Geography, University of Pittsburgh.

**M.G.W.** **Merida Grey Worth,** A.B.

Free Lance Writer in the field of Horticulture.

**M.H.** **Milton Harris,** B.Sc., Ph.D.

President, Harris Research Laboratories, Bethesda, Md.; Scientific Editor, Natural and Synthetic Fibers Abstract Service.

**M.H.Sm.** **Maurice H. Smith,** M.L.S.

Librarian, Institute of the Aeronautical Sciences.

**M.J.** **Marianna Jenkins,** Ph.D.

Assistant Professor, Department of Aesthetics, Art, and Music, Duke University.

**M.Je.** **Merrill Jensen,** B.A., M.A., Ph.D.

Professor of History, University of Wisconsin.

**M.J.H.** **Rev. Milton J. Hoffman,** A.B., M.A., B.A. (Oxford U.), D.D.

Professor of Church History, New Brunswick Theological Seminary.

**M.K.** **Michael Kraus,** B.S.S., Ph.D.

Professor of History, College of the City of New York.

**M.L.MacL.** **Malcolm Lorimer MacLeod,** B.S., M.S., Ph.D.

Associate Professor of English, University of Florida.

**M.McA.** **Marguerite McAneny,** A.B., A.M.

Custodian, Theatre Collection, Princeton University Library; Dramatics Teacher, Miss Fine's School, Princeton, N.J.; Member, Governing Board, Princeton Community Players.

**M.M.C.** **Mary M. Crawford,** A.B., A.M., Ph.D.

Assistant Professor of Economics, Indiana University.

**M.P.** **Michael Peppe**

Swimming Coach, Ohio State University.

**M.Sa.** **Margaretta Salinger,** B.A.

Senior Research Fellow, Department of Paintings, Metropolitan Museum; Lecturer in Art, New York University.

**N.F.A.** **Nelson F. Adkins,** A.B., A.M., Ph.D.

Associate Professor of English, New York University.

**N.J.B.** **N. J. Berrill,** B.Sc., Ph.D., D.Sc. (U. of London).

Strathcona Professor of Zoology, McGill University.

**N.J.T.** **Neil J. Twombly,** S.J., A.B., S.T.L.

Professor of Latin, Jesuit Novitiate, Wernersville, Pa.

**N.MacM.** **Ney MacMinn,** A.M., Ph.D.

Associate Professor of English, Northwestern University.

**N.M.S.** **Nicholas M. Siniapkin,** E.E. (St. Petersburg Poly. Inst.), E.E.

Electrical Engineer, Department of Public Works, State of New York.

**N.Sl.** **Nicolas Slonimsky**

Conductor of the Apollo Chorus, Boston, Mass.; Lecturer in Music, Simons College.

**O.L.R.** **Olive L. Riley**

Chairman of the Art Department, Washington Irving High School.

**O.S.C.** **Oral Sumner Coad,** B.A., M.A., Ph.D.

Professor of English, Head of the Department of English, New Jersey College for Women.

**O.W.H-Q.** **Olga Wilbourne Hall-Quest,** B.S., M.A.

Teacher of Remedial Reading and Director of the Testing Program, The Masters School, Dobbs Ferry, N.Y.

**P.B.** **Peter Buitenhuis,** B.A., M.A., (Oxon.)

Instructor in English, Yale University.

**P.C.C.** **Paul C. Cottrell**

Lieutenant Commander, United States Navy; U.S. Naval Submarine Base, New London, Conn.

**P.C.R.** **Philip C. Rutledge,** S.B., S.M., Sc.D.

Professor of Civil Engineering, Chairman of the Department of Civil Engineering, Northwestern University.

**P.E. Patricia Egan,** A.B., A.M.

Former Instructor in Art, Washington University.

**P.E.J. Preston E. James,** M.A., Ph.D.

Professor of Geography, Syracuse University.

**P.F. Paul Forcheimer,** M.A., Ph.D.

Teacher, Beth Jacob High School, Brooklyn, N.Y.; Member, American Anthropological Association.

**P.G.G. Paul G. Gelrud,** B.S., M.A., Ph.D.

Associate Professor of Music, University of Manitoba; Chairman, Theory Committee, Western Board of Music.

**P.G.L. Philip G. Laurson,** B.S., B.S. in C.E., M.S.

Associate Professor of Engineering, Mechanics and Civil Engineering, Yale University.

**P.H. Paul Honigsheim,** Ph.D. (U. of Heidelberg).

Professor of Sociology, Anthropology, and Foreign Studies, Michigan State College.

**P.H.A. Park Harris Anderson,** Th.B., Th.M., D.D.

Professor of Missions, New Orleans Baptist Theological Seminary.

**P.H.N. Peter Hugh Nash,** B.A., M.A., M.P.A.

Director, Planning Department, Medford, Massachusetts.

**P.M.A.L. Paul M. A. Linebarger,** A.B., M.A., Ph.D.

Professor of Asiatic Politics, School of Advanced International Studies, Washington, D.C.; Major, Military Intelligence Reserve, United States Army.

**P.N. Paul Nettl,** Ph.D., LL.D. (U. of Prague).

Professor of Musicology, Indiana University; Professor of Musicology, Chicago Musical College.

**P.P.Z. Peter P. Zouboff,** B.A., M.A., Ph.D.

Russian Professor, Berlitz School; Director, Executive Board, St. Vladimir's Orthodox Theological Seminary and Academy, New York, N.Y.; Director, Tolstoy Foundation, New York, N.Y.

**P.R.C.-N. P. R. Coleman-Norton,** A.B., A.M., D.Phil. (Oxford U.).

Kennedy Associate Professor of Latin, Princeton University.

**P.S.D. Paul S. Dull,** B.A., Ph.D.

Assistant Professor of Political Science and History, University of Oregon.

**P.W.T. Philip W. Timberlake**

McIlvaine Professor of English, Kenyon College.

**R.A.A. Rufus A. Andrews,** B.S. in E.E., M.S. in E.E.

Manager of Engineering, Vickers Electric Division, Vickers, Inc., St. Louis, Mo.

**R.A.K. Robert A. Koch,** A.B., M.A., M.F.A.

Assistant in Instruction, Department of Art and Archaeology, Princeton University.

**R.A.P. Richard Alexander Parker,** A.B., Ph.D.

Associate Professor of Romance Languages, New York University.

**R.Bn. Robert Brittain,** B.A., M.A., Ph.D.

Writer and Radio Essayist; Former Assistant Professor of English, Queens College.

**R.B.D. Robert Bruce Dow,** A.B., M.A., Ph.D.

Associate Professor of English, New York University.

**R.C.B. Richard C. Boys,** B.A., Ph.D.

Assistant Professor of English, University of Michigan.

**R.C.H.H. Robert C. H. Heck,** M.E., D.E.

Emeritus Research Professor of Mechanical Engineering, Rutgers University.

**R.C.M. Rufus Clegg Morrow, Jr.,** B.S., M.D.

Assistant Attending Otolaryngologist and Endoscopist, St. Luke's Hospital and North County Community Hospital.

**R.E.L. Raymond E. Lindgren,** Ph.D.

Associate Professor of History, Vanderbilt University.

**R.E.N. Ransom E. Noble, Jr.,** A.B., M.A., Ph.D.

Professor of History, Head of the Department of Social Studies, Pratt Institute.

**R.E.W. Robert E. Wright,** B.A., B.S. in L.S.

Research Associate, Harris Research Laboratories; Assistant Editor, Natural and Synthetic Fibers Abstract Service.

**R.F. Rosalie Feltenstein,** B.A., M.A.

Free Lance Writer.

**R.F.G. Richard Franko Goldman,** B.A.

Executive Director, League of Composers; Associate Conductor, The Goldman Band; Secretary, Literature and Materials Faculty, Juilliard School of Music.

**R.F.N. Ross Franco Nigrelli,** B.S., M.S., Ph.D.

Adjunct Associate Professor of Biology, New York University; Parasitologist and Pathologist, New York Aquarium, New York Zoological Society; Consultant on Fish Diseases, Pure Food and Drug Administration, Federal Security Agency.

**R.F.St. Robert F. Steadman,** B.S., Ph.D.

Controller, Department of Administration, State of Michigan; Professor of Government, Wayne University.

**R.F.T. Robert F. Taylor,** B.S., Ph.D.

Research Chemist, Pittsburgh Plate Glass Co.; Former Technical Service Representative, Commercial Solvents Corp.

**R.G. Robert Gaunt,** B.A., M.A., Ph.D.

Professor of Zoology, Chairman of the Department of Zoology, Syracuse University.

**R.G.B. Robert G. Bowman,** A.B., Ph.D.

Associate Professor of Geography, State University of Iowa.

**R.G.Bo. Richard G. Bozorth,** A.B., A.M.

Instructor in English, University of Pennsylvania.

**R.G.F.** **Richard G. Folsom,** B.S., M.S., Ph.D.

Professor of Mechanical Engineering, Chairman of the Division of Mechanical Engineering, University of California.

**R.G.W.** **Robert Gale Woolbert,** A.B., A.M., Ph.D.

Professor of History, University of Denver; Book Review Editor, *Foreign Affairs.*

**R.H.Bo.** **Richard H. Bolt,** A.B., M.A., Ph.D.

Associate Professor of Physics, Director of the Acoustics Laboratory, Massachusetts Institute of Technology.

**R.H.C.** **Ralph Holt Cheney,** B.S., M.A., M.S., Sc.D.

Professor of Biology, Brooklyn College; Resident Investigator for Economic Plants, Brooklyn Botanic Garden.

**R.H.D.** **Robert H. Dodds,** B.S., C.E., M.S.

Associate Editor, *Engineering News-Record.*

**R.H.F.** **Raymond H. Fisher,** A.B., M.A., Ph.D.

Associate Professor of History, University of California.

**R.H.Fo.** **Richard Harter Fogle,** B.A., M.A., Ph.D.

Associate Professor of English, Tulane University.

**R.H.L.** **Ralph H. Lutz,** A.B., LL.B., Ph.D.

Professor of History, Dean of Graduate Study, Stanford University.

**R.J.M.** **Robert J. Maurer,** B.S., Ph.D.

Associate Professor of Physics, Carnegie Institute of Technology.

**R.K.R.** **Robert K. Root,** B.A., Ph.D., Litt.D., LL.D.

Emeritus Woodrow Wilson Professor of Literature, Emeritus Dean of the Faculty, Princeton University.

**R.L.F.** **Robert L. Fisher,** B.A.

Stockbroker in Tobacco, New York, N.Y.

**R.L.S.** **Robert L. Scranton,** A.B., A.M., Ph.D.

Associate Professor of Classical Archaeology, Emory University.

**R.M.** **R. Matthes,** B.S.S.

Head of the Commercial Division, Industrial Department, W. R. Grace & Co.

**R.M.Br.** **Richard Munthe Brace,** A.B., M.A., Ph.D.

Associate Professor of History, Northwestern University.

**R.M.W.** **Robert M. Wallace,** A.B., A.M., Ph.D.

Member, Department of English, University of Alabama.

**R.N.** **Reinhold Niebuhr,** B.D., A.M., D.D., LL.D., D.Litt., S.T.D.

Vice-President of the Faculty and Professor of Christian Ethics, Union Theological Seminary.

**R.Ne.** **Rexford Newcomb,** B.S., M.Arch., M.A.

Professor of History of Architecture, Dean of the College of Fine and Applied Arts, Director of the Bureau of Community Planning, University of Illinois.

**R.P.T.** **Royle P. Thomas,** B.S., M.S., Ph.D.

Professor of Soils, University of Maryland.

**R.S.C.** **Ruth Shonle Cavan,** Ph.B., M.A., Ph.D.

Assistant Professor of Sociology, Rockford College.

**R.S.H.** **Richard S. Hill,** B.A.

Reference Librarian, Division of Music, Library of Congress.

**R.S.Wi.** **Robert S. Williams,** S.B., Ph.D. (U. of Göttingen).

Emeritus Professor of Metallurgy, Massachusetts Institute of Technology.

**R.T.** **Ruthven Todd**

Author; Free Lance Writer; Former Visiting Professor of Creative Writing, State University of Iowa.

**R.Ta.** **René Taupin,** Ph.D.

Associate Professor of Romance Languages, Hunter College.

**R.T.H.** **Robert T. Hatt,** Sc.B., Ph.D.

Director, Cranbrook Institute of Science; Former Assistant Curator of Mammals, American Museum of Natural History.

**R.V.S.** **Ronald V. Sires,** A.B., Ph.D.

William Kirkman Professor of History, Whitman College.

**R.W.** **Raymond Walters, Jr.,** A.B., M.A., Ph.D.

Member of the Editorial Staff, *Saturday Review of Literature.*

**R.W.C.** **Robert W. Chambers,** B.J., B.S., M.J.

Assistant Professor of Journalism, Texas State College for Women.

**R.W.K.** **Ruth Wedgwood Kennedy,** B.A., Diploma (Oxford).

Lecturer in Art, Smith College; Former Lecturer, Toledo Art Museum.

**R.W.Ma.** **Robert W. Mayer,** Ph.D.

Associate Professor of Economics, University of Illinois.

**R.W.R.** **R. W. Roop,** A.B.

Physicist, Research Center, Johns Manville Co.

**R.W.S.** **Ralph W. Steen,** A.B., A.M., Ph.D.

Professor of History, University of Texas.

**S.A.** **Sherman Abrahamson,** B.A., M.A.

Member of the Staff, Environmental Research Division, Quartermaster Corps, Washington, D.C.

**S.C.** **Sidney Cowell**

Free Lance Writer in the field of Music.

**S.D.At.** **Samuel D. Atkins,** A.M., Ph.D.

Associate Professor of Classics and Sanskrit, Princeton University.

**S.E.** **Stefan Einarsson,** M.A. (U. of Iceland), Ph.D. (U. of Oslo).

Professor of Scandinavian Philology, Johns Hopkins University; Vice-Consul of Iceland, Baltimore, Md.

**S.E.G.** **Sidney Erwin Glenn,** Ph.D.

Associate Professor of English, University of Illinois.

**S.F.F.** **Stephen F. Fogle,** A.B., A.M., Ph.D.

Associate Professor of English, University of Florida.

**S.G. Stephen Gilman,** B.A., Ph.D.

Associate Professor of Romance Languages, Ohio State University.

**S.Gl. Samuel Glasstone,** B.Sc., M.Sc., Ph.D., D.Sc. (all of London).

Professor of Chemistry, Boston College; Consultant, U.S. Atomic Energy Commission.

**S.G.I. Samuel Guy Inman,** A.B., A.M., LL.D.

Advisor to U.S. Department of State, U.S. Office of Education, League of Nations, Pan American Conference, Bogotá Conference.

**S.J.H. Samuel J. Hurwitz,** A.B., L.L.B., A.M., Ph.D.

Professor of History, Department of History, Brooklyn College.

**S.McG. Stuart McGregor,** B.A., M.J.

Associate Editor, *The Dallas Morning News;* Editor, *Texas Almanac.*

**S.M.M. Sally M. Middleman,** B.A., M.S.

Free Lance Writer.

**S.N.F. Sydney Nettleton Fisher,** A.B., A.M., Ph.D.

Associate Professor of History, Ohio State University.

**S.Van V. Samuel Van Valkenburg,** Ph.D. (U. of Zürich).

Professor of Geography, Director of the Graduate School of Geography, Clark University.

**T.B.J. Tom B. Jones,** A.B., M.A., Ph.D.

Associate Professor of History, University of Minnesota.

**T.B.S. Thomas B. Stroup,** A.B., A.M., Ph.D.

Professor of English, University of Kentucky.

**T.F.H. T. Fred Holloway,** B.P.E., M.P.E.

Professor of Physical Education, State Teachers College, Cortland, N.Y.

**T.G.R. Thomas G. Ratcliffe, Jr.**

Former Staff Member, Play Department, Columbia Pictures Corp.

**T.M.P. Thomas Marc Parrott,** A.B., A.M., Ph.D. (U. of Leipzig).

Emeritus Professor of English, Princeton University.

**T.R. Theodore Ryder,** B.A.

Free Lance Writer.

**T.R.H. Thomas Robson Hay,** B.S., E.E.

Writer in the field of American History.

**T.S. Tom Stewart**

Public Relations Officer, Department of Conservation, State of Tennessee.

**V.A.T. Victor A. Tiedjens,** B.S., M.S., Ph.D.

Director, Virginia Truck Experimental Station; Former Associate Professor of Vegetable Gardening, Rutgers University.

**V.B.Z. Virgil B. Zimmermann,** A.B., A.M.

Assistant Professor of Political Science, DePauw University.

**V.E. Victor Erlich,** M.A., Ph.D.

Assistant Professor of Russian Language and Literature, University of Washington.

**V.H.C. Victor H. Cahalane,** B.Sc., M.F.

Chief, Biology Branch, National Park Service; Former Director, Cranbrook Institute of Science.

**V.L.L. Victor L. Loosanoff,** B.S., Ph.D.

Director, U.S. Fish and Wildlife Service Biological Laboratory, Milford, Conn.; President, National Shellfisheries Association.

**W.A.Del M. William A. Del Mar,** A.C.G.I.

Chief Engineer, Habirshaw Cable and Wire Division; Phelps Dodge Copper Products Corp.; Former Assistant Electrical Engineer, Interborough Rapid Transit Co., New York, N.Y.

**W.B.C.W. W. B. C. Watkins,** B.A., B.A. (Oxford U.) M.A. (Oxford U.), L.Litt. (Oxford U.).

Lecturer in English, Louisiana State University.

**W.B.H. William B. Hesseltine,** B.A., M.A., Ph.D., Litt.D.

Professor of History, University of Wisconsin.

**W.C. Woodstock College**

A group of Philosophy and Theology Students directed by Professors of Woodstock College, Woodstock, Md.

**W.C.DeV. William C. De Vane,** B.A., Ph.D., Litt.D., L.H.D.

Emily Sanford Professor of English, Dean of Yale College, Director of University Divisions of Humanities and Social Sciences, Yale University.

**W.C.He. William Claud Henry,** B.A., M.A., Ph.D.

Associate Professor of English, University of Omaha.

**W.C.T. Willard Chandler Thompson,** B.Sc., Ph.D.

Professor of Poultry Husbandry, Chairman of the Department of Poultry Husbandry, Rutgers University; Poultry Husbandman, New Jersey State Agricultural Experiment Station.

**W.D.B. W. D. Brush,** B.S., M.A., Ph.D.

Former Member, U.S. Forestry Service.

**W.D.T. William Darby Templeman,** A.B., A.M., Ph.D.

Professor of English Language and Literature, University of Southern California.

**W.E.A. William Eugene Anderson,** B.A.

Free Lance Writer.

**W.E.E. W. Elmer Ekblaw,** A.B., A.M., Ph.D., Sc.D.

Professor of Geography and Geology, Clark University.

**W.Fr. Wolf Franck,** A.M.

Free Lance Writer; Reference Assistant, Music Division, New York Public Library.

**W.F.A. William Foxwell Albright,** Ph.D., Litt.D., D.H.L. LL.D., Th.D.

Professor of Semitic Languages, Johns Hopkins University; Vice-President, American Schools of Oriental Research; Vice-President, Asia Institute.

**W.F.Ba. Walter F. Bartsch**

Artist; Free Lance Writer; Instructor in Art, Hunter College.

**W.H.B. William H. Berry,** M.D., F.A.C.S.

Associate Attending Surgeon, St. Luke's Hospital; Attending Surgeon, Sea View Hospital, New York, N.Y.

**W.I. Wilton Ivie,** B.S., M.S.

Editor, Technocracy, Inc., New York, N.Y.; Former Curator of Spiders, University of Utah.

**W.J. Wendell Johnson,** B.A., M.A., Ph.D.

Professor of Speech Pathology and Psychology, Director, Speech Clinic, University of Iowa.

**W.Jo. Walter Johnson,** A.B., M.A., Ph.D.

Professor of History, Chairman of the Department of History, University of Chicago.

**W.J.H. William James Hail,** B.D., M.A., Ph.D.

Emeritus Professor of History, College of Wooster; Former Dean and Acting President, College of Yale in China.

**W.J.Ha. William J. Hamilton, Jr.,** B.S., M.S., Ph.D.

Professor of Zoology, Cornell University.

**W.La. Wladimir Lakond**

Director, Serious Music Department, Southern Music Publishing Company, Inc.; Pianist.

**W.Li. William Lichtenwanger,** B.M., M.M.

Assistant Reference Librarian, Music Division, Library of Congress; Associate Editor, *Notes;* Chairman, Southeastern Chapter, American Musicological Society.

**W.McE. Walter McElroy,** B.A.

Former Editor, *American Guide Series,* Hastings House.

**W.Mo. William Montagna,** M.D.

Member, Department of Anatomy, Long Island College of Medicine.

**W.M.W. W. Menzies Whitelaw,** B.A., B.D., A.M., Ph.D.

Visiting Professor of History, American International College; Former Associate Professor of History, University of Saskatchewan.

**W.N.W. William N. Woodbury,** Ph.B.

Assistant Chief Engineer, Virginia Bridge Company.

**W.O.S. William O. Shanahan,** A.M., Ph.D.

Associate Professor of History, University of Notre Dame.

**W.P.R. William Peirce Randel,** B.S., A.M., Ph.D.

Associate Professor of English, Director of American Studies, Florida State University.

**W.R. William Ringler,** A.B., Ph.D.

Assistant Professor of English Literature, Princeton University.

**W.Ru. William Ruff,** B.A., Ph.D.

Associate Professor of Humanities, University of Florida.

**W.S.N. William S. Newman,** B.S., M.A., Ph.D.

Assistant Professor of Music, Graduate School, University of North Carolina.

**W.S.V. Wayne S. Vucinich,** A.B., M.A., Ph.D.

Assistant Professor of History, Stanford University.

# THE PRONUNCIATION SYSTEM

The system employed to indicate pronunciations in this encyclopedia is based on the alphabet of the International Phonetic Association. Inasmuch as the sounds that occur in the various languages of the world far exceed in number the letters of the English alphabet, any system designed to represent all these sounds must have recourse to a set of symbols that may or may not be closely related to the familiar alphabetical characters. The International Phonetic Alphabet has two notable advantages: it is widely known beyond the boundaries of any one nation, and it is readily applicable to all the languages of the world.

Certain modifications of the International Phonetic Alphabet have been considered desirable for the purposes of this encyclopedia. Thus, instead of the symbols *ʃ*, *ʒ*, *θ*, and *ð*, with which many readers are unacquainted, the more familiar combinations *sh*, *zh*, *th*, and *t͟h* have been employed. This modification violates the excellent principle that a single sound should be represented by a single character, but it makes the transcriptions easier for the ordinary reader to comprehend; wherever the letters that form these combinations are to be pronounced consecutively and separately, a raised period is set between them. A modification of opposite nature is introduced in the use of the single letter *j* to represent a combination of sounds which might also be transcribed *dʒ* or *dzh;* this modification, like the previous one, has been made for the purpose of simplifying the system for English readers. The consonantal sound *y,* for the same reason, is represented by the letter *y* rather than the letter *j*. In the table of vowel equivalents, the symbols *ö* and *ü* have been adopted from German for the rendering of certain vowels that occur in German and other languages but not in English, the assumption being that readers of foreign languages will generally find these symbols more illuminating than they would find alternative phonetic equivalents. In the use of the symbol *r,* no attempt has been made to distinguish between variations in the pronunciation of the sound that it represents; it is assumed that each reader will give to the symbol *r* precisely the pronunciation that he gives to the letter *r* in a written word. Furthermore, the single symbol *χ* has been used to represent not only the palatal voiceless fricative found, for example, in the German word *ich,* but also the velar voiceless fricative found in the German word *ach;* since, as a rule, the vowel that precedes the fricative automatically makes the sound that follows it either palatal or velar, it is unnecessary to indicate the distinction by phonetic symbols.

## TABLE OF EQUIVALENTS

### Consonants

| *Phonetic Symbol* | *Sound Represented* |
|---|---|
| b | *b*ob |
| d | *d*id |
| f | *f*orfeit |
| g | *g*ag |
| h | *h*ot*h*ouse |
| j | *j*u*dg*e |
| k | *c*a*k*e |
| l | *l*oval |
| m | *m*i*m*e |
| n | *n*o*n*e |
| p | *p*rop |
| r | *r*oar |
| s | *s*auce |
| sh | ha*sh*i*sh* |
| t | *t*rot |
| th | *th*irty-*th*ree |
| t͟h | o*th*er *th*an *th*is |
| v | *v*i*v*id |
| w | *w*ood*w*ork |
| y | *y*esteryear |
| z | pri*z*es |
| zh | plea*s*ure, a*z*ure |
| ŋ | si*ng*i*ng* |
| χ | (Ger.) i*ch*, a*ch* |

# THE PRONUNCIATION SYSTEM

## Vowels

| *Phonetic Symbol* | *Sound Represented* |
|---|---|
| ɑ | f*a*ther, c*a*r |
| ɑ̃ | (Fr.) él*an*, *en* |
| ɒ | wh*a*t, n*o*t |
| a | *a*sk, *a*nswer; (Fr.) *a*ttacher |
| æ | h*a*t, b*a*ck |
| æ̃ | (Fr.) v*in*, m*ain* |
| e | f*a*te, *e*lite |
| ɛ | y*e*t, sp*e*ll |
| ə | mak*e*r, *a*go |
| ɜ | f*i*rst, b*u*rn |
| i | *e*ve, benz*i*ne |
| ɪ | *i*f, st*i*ng |
| o | n*o*te, *o*ld |
| õ | (Fr.) b*on*, r*om*pre |
| ö | (Ger.) schön, böse |
| ɔ | *o*rb, *a*ll |
| œ | (Fr.) l*eu*r; (Ger.) können |
| œ̃ | (Fr.) br*un*, l*un*di |
| u | r*u*le, pr*u*ne |
| ü | (Fr.) cr*u*; (Ger.) grün |
| ʊ | b*u*ll, b*u*sh |
| ʌ | b*u*t, s*o*n |

## Diphthongs

| | |
|---|---|
| ai | cr*y*, sp*i*ne |
| au | pr*ow*, l*ou*d |
| ɔi | t*oy*, p*oi*nt |

The tilde (˜), wherever used, indicates that the vowel above which it appears is nasalized.

In the application of this system in the encyclopedia, indications of pronunciation are restricted to article heads, particularly to those that may be supposed to present difficulties in pronunciation. In these cases the phonetic symbols are printed in square brackets following the head, and stresses are indicated by accents placed immediately after stressed vowels, a heavy or a light accent indicating respectively a primary or a secondary stress. When more than one pronunciation of a given word is in wide use, the variations appear in the phonetic transcription.

The phonetic symbols are intended to serve as a flexible guide to pronunciation, not as a standard of correct usage. Usage varies so greatly in the English language between different groups of society, between different localities, and between different nations speaking the same language, that the selection of a norm is, for the purposes of an encyclopedia, practically out of the question. Users of the encyclopedia may find distinctions in pronunciation which they do not themselves observe in their ordinary speech, but in such cases the system of transcription is sufficiently flexible to admit variations. For example, many speakers, especially in the United States, pronounce the vowel in *what* virtually as they pronounce the *a* in father; the encyclopedia's symbol for the vowel in *what* is ɒ, but when these speakers encounter that symbol in a phonetic transcription, they will presumably give it approximately the value of the symbol ɑ wherever it occurs.

# COLLIER'S ENCYCLOPEDIA

# VOLUME EIGHTEEN

## SODALITE to TZU HSI

**SODALITE** [so′dəlait], a feldspathoid mineral containing sodium aluminum silicate with chlorine, $Na_4Al_3Si_3O_{12}Cl$. It may have a deep blue color. Sodalite tends to crystallize in the twelve-faced spheroidal dodecahedron. It also has poor dodecahedral cleavage (six directions). The environment for sodalite is the same as for another feldspathoid, nepheline, with which it is often associated. The precipitating magma must have been relatively low in silica. Massive blue sodalite occurs in Quebec, Ontario, and British Columbia. K. K. L.

**SODA NITER,** a mineral named after a chemical compound, $NaNO_3$. It ordinarily occurs in masses or as an incrustation. Soda niter is soluble, with a characteristic cooling taste. It is found only in regions of exceptional acidity. The outstanding deposits are in northern Chile, where the mixture of soda niter, salt, gypsum, and silt is called caliche. The origin of the Chilean caliche is in dispute. It is vigorously exploited for the manufacture of nitrate fertilizers. Soda niter is also used in making explosives. K. K. L.

**SODDY, FREDERICK** [sɒ′di] (1877- ), English chemist, was born at Eastbourne, Sussex, Sept. 2, 1877. He is noted for his work on the rate at which radioactive substances disintegrate, and the origin and nature of isotopes. Educated at Eastbourne College, the University College of Wales, and Merton College, Oxford, Soddy became demonstrator in chemistry at McGill University, Montreal, undertaking research on radioactivity with Lord Rutherford there in 1900, then with Sir William Ramsay at the University College, London, in 1903, as a lecturer at Glasgow from 1904 to 1914, as professor of chemistry at Aberdeen from 1914 to 1919, and finally as Lee's professor of inorganic and physical chemistry at Oxford from 1919 to 1936, when he retired. Soddy originated the disintegration and displacement laws of radioactive elements, which led to his discovery of isotopes, which he named and first described in 1912. He was also a protagonist of the virtual wealth theory of money, and of the application of laws of conservation to economics, writing several monographs on the subject. He was president of the Roentgen Society in 1905, was elected Fellow of the Royal Society in 1910, and was awarded the Nobel Prize in chemistry for 1921. H. N. A.

*FREDERICK SODDY*

KEYSTONE VIEW COMPANY

**SÖDERBERG, HJALMAR** [sö′dərbæry] (1869-1941), Swedish author, was born in Stockholm on July 2, 1869. After completing his education he spent some time as a journalist in southern Sweden, but he soon returned to Stockholm and from 1895 onward devoted himself to creative writing. He has often been called the typical Stockholm writer, but for many years he made his home in Copenhagen, where he died on Oct. 14, 1941.

Söderberg was influenced at first by Herman Bang, later by Guy de Maupassant and especially Anatole France, who seems to have helped him find his own style. He was strongly opposed to the literary movement represented by Verner von Heidenstam and was closer to August Strindberg, whose work he tried in some degree to carry on. Söderberg, however, was never the leader of a literary school; he always stood alone. As a matter of style, he ranks among the foremost in Swedish literature. Ironical, skeptical, and resigned, he is a typical representative of the *fin de siècle* mood in its Swedish aspect.

Söderberg's literary production consists of only a few volumes. He wrote four novels, of which *Martin Bircks ungdom* (1901), English translation *Martin Birck's Youth* (1930), is best known; a few collections of short stories, some of them translated in *Selected Short Stories* (1935); and three plays, among them *Gertrud* (1906). Throughout his life he was interested in theology and the history of religion, but his writings on these subjects were not seriously received by scholars. In *Sista boken* ("The Last Book"), a miscellany published posthumously in 1942, he pointed out the danger to modern civilization that was posed by the rise of Nazism in Germany. A. Wi.

**SÖDERGRAN, EDITH** [sö′dərgran] (1892-1923), Swedish-speaking Finnish poet, was born in St. Petersburg (now Leningrad), Apr. 4, 1892, and lived in Raivola, in what is now Karelia. In 1916 she published her first collection, *Dikter* ("Poems"), which showed her strong temperament and her rich visionary fancy. More difficult are her later lyrics, such as those published in *Landet som icke ar* (1925)

("The Land Which Does Not Exist"). Here she tried to carry out the program of Expressionism, to make poetry a spontaneous expression of the emotions, without the control of the intellect. She wrote some of her best poems, which were typically hymns about the beauty of life or visions of the blessings of eternity, while suffering from an incurable illness. Her work has been of great importance in the literary development of Finland as well as Sweden, and she has influenced an entire school of later Scandinavian poets. She died on June 24, 1923. A selection of her lyrics, *Min Lyra* (1929) ("My Lyre"), was published after her death.

A. Wi.

**SODIUM** [so′diəm], symbol Na (Latin *natrium*), atomic number 11, at. wt. 22.997, density 0.971, m.p. 97.5° C., b.p. 880° C. Sodium was first prepared by Humphry Davy, in 1807, by the electrolysis of sodium hydroxide, and it is still made that way. Attempts to manufacture it by the electrolysis of fused chloride have met with failure because of the destruction of the electrodes. Sodium is widely distributed as common salt, sodium chloride, NaCl. Beds in Germany have reached a depth of 4,000 ft.; in New York, 75 ft.; and in Michigan, 400 ft. Deposits in Poland are said to be 50 mi. long, 20 mi. broad, and 1,200 ft. thick. It is estimated that the oceans contain enough salt to cover the earth's land surface to a depth of 400 ft. Sodium is abundant also in Chile saltpeter, $NaNo_3$, and in mineral silicates, borates, carbonates, and sulphates. It constitutes 2.5 per cent of the earth's crust.

**Properties.** Sodium is the third member of Group I-A of the periodic table. It is the second member of the alkali metal group, which includes lithium, sodium, potassium, rubidium, cesium, and francium. These metals have one electron in a large outer orbit; this property results in a metal which is soft, light in weight, malleable, low melting, and very active chemically. Sodium is one of the most active of all metals and therefore displaces most of them. For example, it reacts with aluminum chloride to produce aluminum. H. Y. Castner's researches on this method in 1880 for its industrial possibilities led him to discover a cheap method for producing sodium in abundance. Sodium reacts with oxygen of the air to form the peroxide $Na_2O_2$. A piece of sodium is ordinarily coated with a white oxide, $Na_2O_2$, which on being scraped away reveals a silvery luster. The oxide $Na_2O$ dissolves in water to form sodium hydroxide. Thrown upon water, sodium liberates hydrogen. The heat of reaction is not as great as with potassium, so that the hydrogen is not likely to ignite spontaneously unless the piece of sodium is large. Sodium is an excellent conductor of electricity and is processed into wire for carrying 4,000-ampere current, where light weight is desirable. Sodium is so malleable and ductile that it may be drawn out into wire. The organic chemist has sodium presses about the laboratory to prepare sodium wire for removing water from his organic chemicals. Sodium amalgam formed with mercury is less active than sodium, alone. The amalgam with potassium contains 24 per cent sodium and 76 per cent potassium. Sodium forms a hydride, NaH, which reacts with CO to form sodium formate, HCOONa. The solubility of sodium chloride changes little with temperature; 26.3 per cent at 0° C. and 28.1 per cent at 100° C. *See also* Alkali Industry; Salts.

H. N. A.

**SODOM** [sɒ′dəm]. Sodom and Gomorrah, Admah, Zeboiim, and Zoar were the five Cities of the Plain, which were notorious for their wickedness, according to the Book of Genesis. In his wrath the Lord destroyed the first four with a hail of "brimstone and fire," but Zoar was spared and served as a place of temporary refuge for Lot and his two daughters, Lot's wife having been turned into a "pillar of salt." In several passages in both the Old and New Testaments the fate of Sodom and Gomorrah is recalled as a warning of what the Lord has done in the past and can do in the future to punish the wrongdoer. Yet both the location and manner of destruction of these Cities of the Plain have remained a mystery.

The Biblical evidence points to a location at the southern end of the Jordan River-Dead Sea Valley, in a mountain-hemmed region that is nearly 1300 feet below sea level. Lot, having selected the fertile Jordan Valley, pitched his tents as far as Sodom. The four Eastern Kings, who twice invaded and raided the Cities of the Plain, fought with the five kings in the "vale of Siddim," which was full of wells of asphalt ("slime pits" in the older translations). Both ancient and modern writers attest the presence of asphalt (Greek) or bitumen (Latin) around the Dead Sea, especially around the southern part. Josephus, writing in Greek, calls the Salt Sea (the modern Dead Sea), "Lake Asphaltitis."

At the southwest corner of the Dead Sea rises a low mountain made up in part of compact crystalline salt, which the Arabs today call Jebel Usdum, the Mount of Sodom. This salt mass, a hundred feet in height, is continually being eroded and creviced, and thus are formed pinnacles of salt that simulate a human figure. Biblical and Mohammedan traditions, ancient and modern travelers, have associated such formations with Lot's wife. So pecularities of the Mount of Sodom suggest that Sodom was located near the southern end of the Dead Sea, a region that is quite lush with vegetation, especially where five streams empty into the southeast part of the Dead Sea and where there is irrigation.

Archaeological evidence also supports the locating of Sodom and the other Cities of the Plain in this region. A pilgrimage place, Bab ed-Dra, has been discovered east and above the southern part of the Dead Sea, which appears to have been periodically frequented during the period about 2300 and 1900 B.C., to judge by the pottery found at the site. But no settlements have been found which furnished the attendants at the festivals at Bab ed-Dra, and yet they must have been situated near by. There remains only one place in which to locate the ill-fated Cities of the Plain—under the present waters of the southern embayment of the Dead Sea. Here, south of the peninsula el-Lisan ("The Tongue"), the maximal depth of the water is less than twenty feet whereas north of the peninsula soundings have recorded depths of over 1100 feet. This area was at one time a fertile plain, called the Valley of Siddim. Obviously the water level of the Dead Sea has been rising, and records taken over a period of years indicate an average rise of from 2½ to 3½ inches a year. Striking proof of this phenomenon is the presence of dead trees now a mile out from shore in the heavily concentrated salt water at the southern end of the Dead Sea. And now the parenthetical notation in Genesis 14:3 becomes clear: "the vale of Siddim (which is the Salt Sea)," in other words, which is now under the Salt Sea.

The destruction of Sodom and Gomorrah was brought about by the Lord after Abraham had failed to find even ten righteous men in all of Sodom. According to Genesis 19:24-28, the Lord rained "brimstone and fire" upon the Cities of the Plain. Recent investigations, conducted by geologists for certain oil companies, have revealed the presence of petroleum in the region around Jebel Usdum, as well as seepages of asphalt. The foul odors and the imperceptible soot which, according to ancient writers, arose from the Dead Sea and tarnished metals, may be explained as natural gas, the nature

of which was, of course, unknown to the ancients. Thus a possible explanation of the destruction is that oil and the accompanying emanations of gas may have been ignited by lightning, or an earthquake, so common in this region, may have overturned hearth-fires, and a great conflagration resulted. It is to be noted that Abraham, from a place near Hebron, saw smoke rising from the Plain, which went up "as smoke of a furnace," a description applicable to the burning of oil and gas. The abandonment of the pilgrimage site, about 1900 B.C., may therefore date the destruction of Sodom and Gomorrah about the end of the twentieth century B.C. J. P. H.

**SOEMBA, SUMBA,** or **SANDALWOOD** [su′mbə], an island in the Indian Ocean, southwest of Flores Island, from which it is separated by Soemba Strait. It belongs to the Lesser Sunda Islands, east of Java, and it has many bays and good anchorage along the coast. Soemba lies southeast of Sumbawa and southwest of Flores, about 38 mi. from each. It is 140 mi. long from northwest to southeast and 24 to 50 mi. in width. It rises abruptly from the sea and has only the narrowest of coastal plains. Differing from the islands that lie just to the north, it is sedimentary, and not volcanic, in formation. For the most part, it is a plateau about 2,000 ft. in elevation, with a few peaks rising higher, though none exceed 4,000 ft.

Soemba's alternate name is Sandalwood Island, but the sandalwood trees are now gone from the coastal sections. There are, however, many still growing in the interior. Forests are present but are far less dense than those of the islands farther west; for while Soemba has a fair amount of rain, there are times during the year when very little falls, and in the month of July there is usually none. The main occupation of the population is agriculture and cattle-breeding, and the horses of Soemba Island are renowned throughout the archipelago. The art of weaving is highly developed by the residents. The town of Waingapoe, which is on an inlet on the northern coast, is the headquarters of an assistant resident. Waikalo is a village on the northwest coast. From both these towns the island exports the sturdy little horses for which Soemba is well known. Maize, a little rice, sago, tobacco, indigo, and a small amount of cotton are grown.

Formerly the island was a slave-trading center. The island was first mentioned by Antonio Pigafetta in 1522, and was given the name of Sandalwood Island in 1663 because of the sandalwood trees which then covered it. The Dutch East India Company maintained a functionary on the island, which came under the residency of Timor in 1820. Direct control was assumed by the Netherlands in 1866. In 1946, Soemba became part of the State of East Indonesia, one of the former constituents of the United States of Indonesia, all of which ceased to exist on Aug. 17, 1950, when they became a part of the independent Republic of Indonesia. R. G. B.

**SOEMBAWA** or **SUMBAWA** [sumbɑ′wə], one of the Lesser Sunda Islands east of Java in the Republic of Indonesia at 8° 30′ S. lat. and 118° E. long. Soembawa lies between the island of Lombok on the west and the Flores Sea on the northeast. The island, about 175 mi. long and 55 mi. across at its widest point, has a quite irregular coast line and one of the best harbors in the republic at Bima Bay on the northeastern coast. Although mountainous, the soil is fertile and suitable for producing tropical crops. Horse and cattle raising are important occupations. Raba, the chief town, is located on Bima Bay, and the highest point of the island is Mt. Tambora, at the tip of the northern peninsula, which is now 9,354 ft. in height but was, until 1815, about 13,000 ft. in elevation. A volcanic eruption in that year reduced the peak. R. G. B.

**SOERABAJA** or **SURABAYA** [sʊrəbɑ′yə], the second-ranking trade center and principal naval base of the Republic of Indonesia, situated in Java on the Mas River and on the narrow strait between Java and Madoera or Madura Island, 400 mi. northeast of Jogjakarta or Djokjakarta. The harbor and naval base, whose entrance is guarded by fortresses on the island of Madoera, offer every facility to warships, up to and including cruisers. Railroads and excellent highways link Soerabaja with all of Java and airlines connect it with the principal cities on the island as well as with other terminals in the archipelago. The population is estimated at 600,000.

Chief industrial establishments are tool factories, shipping yards, and metal works. Main exports are sugar, coffee, tobacco, maize, tapioca, and hides. B. L.

**SOERAKARTA, SURAKARTA,** or **SOLO** [sʊrəkɑ′rtə, so′lo], a town in south central Java in the Republic of Indonesia, situated on the Solo River, 35 mi. east of Jogjakarta. Soerakarta has railroad connections with Jakarta (Batavia), Semarang, and Soerabaja. The population is estimated at 170,200. It is the seat of the Susuhunan (Prince) of Soerakarta, whose palace, called the Kraton, occupies a large part of the town and has more than 10,000 people living within its walls. A large mosque and many smaller ones are situated there.

Soerakarta has many native industries including goldsmithing, saddle-making, and the painting of the famed Solo batiks. The main products of this region are rice, indigo, coffee, sugar, tobacco, cocoa, and kapok. B. L.

**SOFIA** or **SOFIYA** [so′fiə, sofi′ə; sɔ′fɪyɑ], capital of the "people's republic" of Bulgaria and of the county of Sofia, located in west central Bulgaria on a mountain-enclosed plain at about 1,700 ft. elevation. The Bogana River, a tributary of the Golem Isker, passes northward through the city. Sofia is the most centrally located of all cities in the Balkans, with easy passes in all directions from its mountain-rimmed location. Sofia's climate is, on the whole, agreeable. Highest temperatures may reach 100° F. in summer but nights are generally cool, and the mercury in winter often drops below

*The National Opera at Sofia, Bulgaria, one of the capital's most impressive buildings*

BURTON HOLMES FROM EWING GALLOWAY

zero. Yearly rainfall averages less than 30 in., winter being the driest period.

The site of modern Sofia has long been occupied by towns of varying importance. A city founded there about A.D. 100 by Trajan was known as Serdica and served as an administrative center. Huns burned the town in A.D. 447; its successor was captured in 809 by Bulgars under Tsar Krum. Coming under control of the Byzantine Empire in 1018, the town was renamed Triaditza and served as an outpost city of the Empire for the next 168 years. The Turks took it in 1382 and held it, with the exception of brief occupations by Hungarians in 1443 and Russians in 1829, until 1878. The city became the capital of the Bulgarian principality in 1878 when the Russians freed the Bulgars from the Turks.

The most important industrial city in Bulgaria, Sofia is a sugar-refining center and has a number of metal-products industries and silk, cotton, and woolen mills. In addition it has vegetable-oil extraction industries, breweries, rubber industries, factories making soap, tobacco products, brick and tile, and leather tanneries. It is one of Bulgaria's major rail cen-

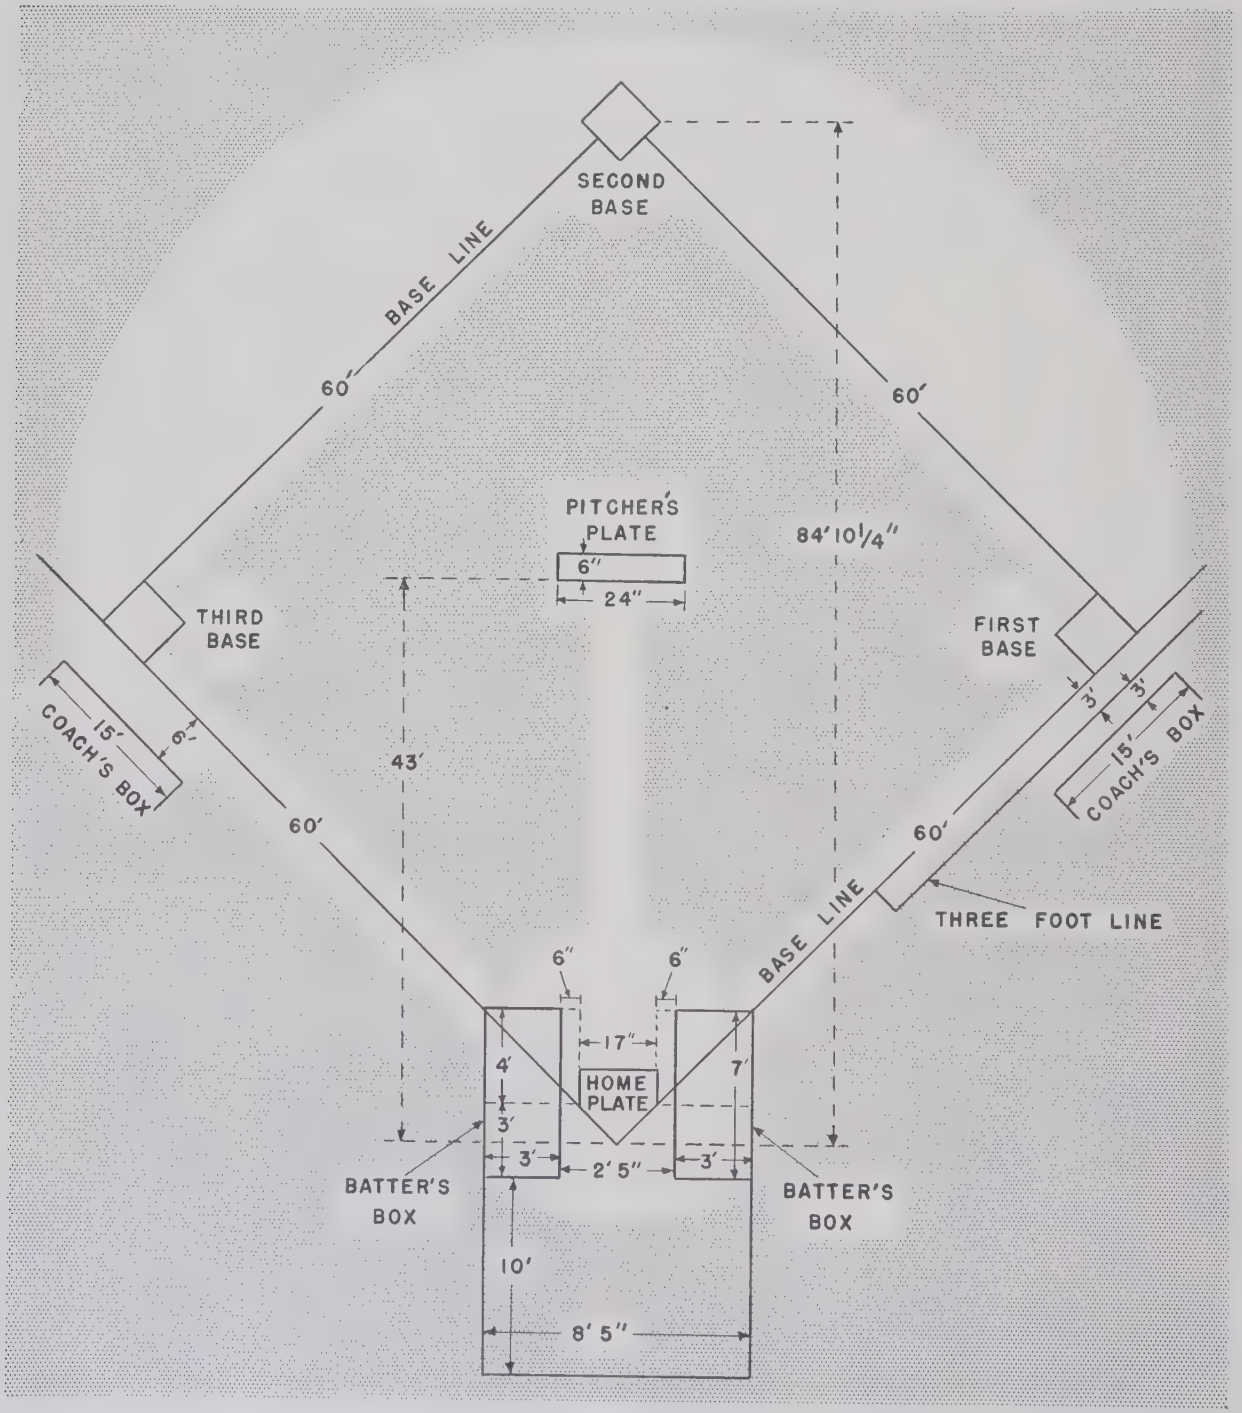

*DIAGRAM OF A SOFTBALL DIAMOND*

ters, and the railway from Paris to Constantinople passes through Sofia. North and south lines provide connections with Romanian and Greek railways by way of the Isker and Struma river valleys. Pop. 1946, 366,925. E. St.

**SOFTBALL,** a form of baseball, an outgrowth of attempts to play baseball indoors. Because of the limited area in indoor arenas, smaller playing fields were laid out. Because of the closer proximity of the players a softer, slower ball was devised. A smaller, lighter bat followed. Finally, because the shorter distance between the pitcher and the batter gave the pitcher too great an advantage, the pitcher was required to throw underhand to the batter. These are still the principal differences between softball and baseball.

The game, called "indoor baseball" at first, made slow progress towards popularity until the late 1920's when it became widely known in Canada. During the early 1930's it was introduced on playgrounds and recreational fields in the United States, and became extremely popular. Played at first principally by children, it was soon adopted by men who found its smaller proportions ideally suited to the limited playing areas available in cities and large towns. The fact that it could be played capably by relatively unskilled players, who would not be able to play baseball with the finesse and co-ordination that that sport demands, added to the game's popularity. Softball, played by practiced athletes, however, can be a fast, skillful game. Despite early efforts to standardize the rules, local practices prevailed, and by 1933, when the first national softball championships were held, it was discovered that the rules varied in almost every section of the country. Official rules were established but have been changed frequently, and discrepancies still exist between various codes. Softball rules are generally similar to baseball rules, with the major exceptions having to do with the size of the field (*see accompanying diagram*), the size and composition of the ball, the size of the bat, the restrictions that are placed on the base runner, and the requirement that the pitcher deliver the ball to the batter with an underhand motion.

National tournaments are sponsored each year by the American Softball Association and the National Softball Congress. *See also* BASEBALL. R. W. Cr.

**SOFT-SHELLED TURTLE,** broadly, any member of the Trionychoidea, one of the three suborders of Testudinata. This turtle is usually pancake-like in form and has a pliable "shell" covered with leathery skin and a soft, tubular snout. The family Carettochelydidae includes only the peculiar pitted-shell turtle, *Carettochelys insculpta,* of New Guinea, the only fresh-water turtle with flippers. The ancient family Trionychidae includes seven living genera, many species of which occur in Asia, Africa, and North America. These species have fleshy lips hiding sharp jaws, and heads that may be retracted readily by bending the neck vertically. The spiny soft-shell *Amyda spinifera* of eastern United States inhabits unpolluted waters, and lays one to two dozen spherical, hard-shelled eggs. It measures 15 in. in shell length, and is eagerly sought as food. M. G. N.

**SOGNEFJORD** [sɔ′ŋəfyor], the longest of the Norwegian fiords, located in western Norway, 50 mi. north of Bergen. It extends eastward from the Atlantic for 136 mi. far into the plateau of southern Norway. From this plateau and the Jotunheimen Mountains to the north, the Sogne receives considerable amounts of water, much of which descends in high falls from the upland surfaces. The mountainous sides of the fiord rise to 5,000 ft., often as precipitous cliffs. Many of the tributary fiords lie so deep that they receive sunlight not at all in the winter and only for a few hours during the summer days. The Sogne averages 3¾ mi. in width but in the tributary fiords often narrows to less than 600 ft. Its waters are deep for most of its length, exceeding 4,500 ft. in some sections. As this tremendous trough cut by the glacier nears the ocean, it becomes much shallowed, until at the coast a rock threshold with shallow water separates the two. The major tributary fiords to the south are the spectacular Naeröfjord, Åurlandsfjord, and Laerdalsfjord, those to the north are the Fjaerlandsfjorden, Sogndalsfjord, Lusterfjord, and Årdalsfjord. The important towns of the Sognefjord are the aluminum center of Höyanger, the resort at Balestrand, and the manufacturing town of Laerdalo. Because of its salt water and great depth, the Sognefjord does not freeze in winter, thus providing a superb year-round artery of travel for the region. Roads parallel the shore for parts of its length, but fiord boats provide the major means of transportation. The wild grandeur of the Sognefjord has made it a favorite with European and American tourists. J. E. V.

**SOHR, MARTIN.** *See* AGRICOLA, MARTIN.

**SOHRAB AND RUSTUM** [sorɑ′b, rʌ′stəm], a narrative poem by Matthew Arnold, published in 1853. It presents, as an episode in Homeric style, a part of the Persian legend of the hero Rustum. Rustum's wife had borne a son, Sohrab, but to keep him with her as long as possible she reported that the child was a girl. Rustum has been traveling in distant countries, finding glory in war. Sohrab, now a young man and a prodigy in warfare, seeks to make himself known worthily to his father and challenges an enemy army to send a single champion against him. Rustum accepts the challenge in disguise, and mortally wounds Sohrab, from whose dying words he learns that his child is a son and that he has killed him. W. D. T.

**SOIL.** Wherever plants grow, soil covers the land. It is a patchwork blanket, varying from place to place. Soil includes many thousands of soil types, just as vegetation includes many kinds of plants. On very young lands, in the high mountains, or near the poles, soils are scarcely more than thin films. Under the tropical rain forest, they may be 10 ft. deep or more. In the United States, useful soils are generally 2 to 5 ft. deep.

Solid rock often lies hundreds of feet beneath the surface, under mixtures of stones, gravel, sand, silt, and clay. But this loose mixture is not soil. Only the surface layers, in which plants have their roots, and in which small animals and micro-organisms live, constitute the soil.

Soils have area as well as depth. Each natural kind of soil is the product of a particular combination of 5 factors: (1) climate, (2) living matter, (3) parent rock, (4) relief, and (5) time. The upper surface of a soil may be nearly flat, or undulating, or hilly. Its bottom is defined by the limit of influences of plant roots and other forces that have changed the loose rock material to soil. The sides of a soil are its boundaries with other soils, where one or more of the five genetic factors change.

Thus, soils are solid pieces of landscape. All the pieces that are alike, wherever they are found in the world, belong to one soil type. These are not scattered about at random, but in an orderly, discoverable pattern. Then, too, soils are dynamic, changing with the rising and sinking of the land;

with the gradual washing away of the surface and the sinking of the soil into fresh material; with the accumulation of ash, dust, or silt on the surface; with changes in plants and animals; and with the long passage of time.

Such natural soils are used by farmers, gardeners, and foresters for production. The farmer makes his arable soil from the natural soil. He may improve its physical structure and fertility a great deal; he may use up its nutrients and allow it to become unproductive, or even to waste away.

## SOIL MORPHOLOGY

If a trench, or pit, is made in a soil down to the unaltered rock material beneath, its characteristics may be studied.

**Soil Profile.** The soil, in the first place, is made up of layers, called horizons. Some or all of these horizons may be thin, scarcely an inch thick; or they may be several inches thick. Sometimes the lines between them are sharp; often one horizon gradually merges into one above or beneath. Each has its own physical and chemical characteristics. These horizons, taken together, are called the soil profile. By studying the profile of many soils, scientists arrange them into a system of classification. Through scientific correlation, a new or unknown soil may be placed in the system.

**Soil Texture.** The relative proportion of particles of various sizes that make up a mass of soil determines soil texture. The individual size-groups, or "separates," range from gravel, the coarsest, through sand and silt to clay, the finest. Clay is by far the most important size-group, since it has the largest amount of surface exposed for physical and chemical actions. The particles in one pound of dry clay have a total surface of about one acre.

Actual soil horizons consist of mixtures of particle sizes. The words used to name their texture, beginning with those having the most clay, are: clay, clay loam and silty clay loam, silt loam, loam, sandy loam and fine sandy loam, loamy sand, and sand. The terms gravelly, cobbly, and stony may be used to modify these names if large amounts of gravel, cobbles, or stones are present.

Soils very rich in gravel and sand hold little water between rains. Clay soils are commonly sticky when wet, and hard when dry. Loam soils having a fair mixture of sand, silt, and clay are most likely to hold water without retaining too much. But the effect of the clay depends on its chemical composition. Soils of equal clay content vary widely in stickiness and hardness.

Then, too, the texture of the several horizons in the soil profile may (or may not) vary greatly. In other words, three soils may have sandy-loam surface horizons: one may be underlain by coarse gravel, another by loam, and a third by tight, heavy clay. Other things being equal, the first will be too dry for general cultivation, the second about right, and the third too wet, at least during rainy periods.

**Soil Structure.** The grouping of the soil particles into plates, blocks, or granules determines soil structure. At the extremes are structureless soils: those consisting of separate grains, as in sand dunes, and massive clays or hardpans having no regular breakage. A granular structure is best for crop plants; the aim of the farmer must be to produce and maintain such a structure.

**Color.** The color of the horizons tells about the soil's chemical and mineralogical composition. Soils rich in organic matter are black or very dark brown in temperate regions, and dark brown in the tropics. Iron-rich soils are commonly red, although they may be yellow or even gray if they are wet, or have been wet recently. Nearly white soils are thoroughly leached or unusually rich in salts.

**Chemical Composition.** The appearance of the various horizons does not suffice to determine their chemical composition. Acidity can be determined in the field by simple tests. With field tests and experienced observations of color, some compounds may be estimated, but for accurate data, samples of the horizons must be taken into the laboratory.

The larger part of most soil horizons is made up of insoluble compounds of silicon with aluminum, oxygen, hydrogen, iron, calcium, magnesium, and potassium. Yet most of the other 90-odd elements are present, at least in tiny amounts. The relatively insoluble compounds yield, directly, few or no nutrients to plants, but they are extremely important in holding or releasing soluble compounds that do influence plants.

Normal plants must obtain from the soil many nutrients in proper balance including nitrogen, phosphorus, potassium, calcium, magnesium, sulphur, iron, zinc, copper, boron, manganese, and molybdenum. The first six are most commonly lacking in the soil. The last six are needed only in very tiny amounts. The lack of any one of them may limit plant growth, and all are now used in fertilizers.

Soils vary in the total amounts and in the availability to plants of each of these nutrients. Since plants vary a great deal in what they need, a luxuriant native vegetation does not necessarily indicate the presence of abundant nutrients for crop plants, which may have different requirements. This fact is significant since native plants leave their remains in the soil for new plants to use, whereas a farmer may remove the crops, and with them a part of the nutrients.

**Organic Matter.** A great storehouse of plant nutrients is the soil's organic matter. Of first importance is the living matter itself: the trees, grasses, roots, and animals. After this material dies, micro-organisms in the soil decompose it, releasing the nutrients they contained to be absorbed by new plants. A small part of the product of decomposition is a dark-colored, relatively stable material called humus.

## THE GREAT SOIL GROUPS

Soil phases, types, and series are grouped into families, and these families, in turn, into great soil groups. Some 40 to 50 great soil groups are recognized, but some are not well defined, and a few others may be established following further research in the tropics and the subarctic.

There are three great soil groups: zonal, intrazonal, and azonal. The zonal groups, or continental soil types, are those upon which the climate and vegetation have made their full, or nearly full, impress, without local disturbances from extremes of slope or of parent rock. These soils are found on well-drained uplands, nearly level to rolling, over parent materials of mixed physical and chemical composition. The zonal groups dominate the soils of a broad area.

Intrazonal soils also have characteristics that reflect some influence of climate and vegetation; but these soils are principally dominated by some local factor, such as poor drainage or very limy parent material. The bog soil found in swamps is an example of such an intrazonal soil.

The azonal soils have no developed features, since their parent materials have been formed, and may be found associated with any of the other great soil groups. By far the most important azonal group comprises the alluvial soils of the young flood plains and deltas, in which soil-forming processes have not had time to modify the recently deposited parent material.

A general view of the soils of the world can best be had by looking at the five principal zonal groups: the tundra, the podzol, the chernozem, the desert soils, and the latosol.

**Tundra.** Generally, these soils have dark-brown, peaty layers over gray, moist soil. Most are ever-frozen a foot or two beneath the surface. Little use is made of them. In the same region are many bog soils and lithosols. Everywhere in high mountains about the timberline, there are somewhat similar soils, often referred to as "alpine meadow" soils which support vegetation for summer grazing.

**Podzol.** In the cool, humid, forested regions there are light-colored, leached, acid soils. There is a surface covering of raw organic matter, but not much humus. By using lime and fertilizers, and by growing legumes and grasses part of the time, such soils can be made productive. Podzols are much cultivated in northern Europe and in part of North America. Further development of industry and of transportation will make more of them useful, especially for the cultivation of vegetables and for dairying.

Just south of the podzols, in the Northern Hemisphere, are the gray-brown podzolic soils. They are light-colored and leached. They are even more responsive to good management than the podzols, and can be used for a wide variety of crops.

**Chernozem.** These black soils have developed in subhumid temperate regions under tall grasses. They are well granulated and fertile. Most of them are in the interior of continents. They furnish the larger part of the bread grains for the world. Their uncertain climate limits crop production, both as to yield and kinds of crops.

Between the chernozem and the gray-brown podzolic soils are the prairie soils, also developed under grasses, but having more rainfall. Prairie soils are dark-colored and fertile. The only large area of them lies in the American Midwest, centering in Iowa. These soils are most productive of corn and other grains, usually when just plowed.

In passing from the chernozem to the desert, the soils become dark brown (chestnut), brown, and, finally, gray (sierozem). All have a layer of accumulated calcium carbonate (lime) underneath, usually two to four ft. deep and nearer the surface as it approaches the desert. Chestnut soil, and the very best of the brown soils, can be used for grains, although irrigation is often required.

In passing from the chernozem toward the tropics, the soils become more red (reddish chestnut) and merge with the latosol.

**Desert Soils.** Some authorities hold that true deserts have no plants at all, but desert soils include those having scanty vegetation. They are light-colored and unleached. A large part of the desert is wind-swept, rocky, or piled with sand; smooth, deep soils in it respond well to irrigation.

**Latosol.** Several great groups in the tropics and subtropics are included in the latosol. They are leached and relatively porous, and their constituent particles are highly weathered. The red latosols are strongly leached soils of the humid tropics. Although usually rich in clay, they are porous. Thus, quite strong slopes may be safely cultivated. To produce crops on them, the soil must be heavily fertilized, or returned to the forest for 12 or 15 years after short periods of cropping. The reddish-brown latosols, developed on basalt and similar rocks, are more productive. They are found near volcanos, as in Hawaii, and along the mountains of east Africa.

Ground water laterite is found in the tropics and subtropics on nearly level ground having pronounced wet and dry seasons. This soil is one of the most interesting but least productive in the world. In the wet season, the water table may come within 2 or 3 ft. of the surface, while in the dry season it may be many feet deep. The top surface horizons become thoroughly leached and acid. The material underneath undergoes a peculiar type of change. The soil material becomes doughy and can be cut out with a knife into bricks, but when exposed to the air for a few months, it hardens into a slag-like rock. It is called laterite. Once hardened, it is extremely resistant to weathering. Throughout the tropics, one may find large masses and areas of laterite, laterite crusts underlying almost any soil. In many latosols, small concretions of laterite are formed, rather than crusts.

The most productive soils in the tropics are young soils, such as the soils of steep slopes rejuvenated by erosion. When cultivated, such soils must be protected by terraces or strip cropping. Large areas of soils such as those in Java, for example, are kept fertile by frequent showers of volcanic ash.

An extremely wide range of crops can be grown on good latosols. Hundreds of millions of acres of good soils in the tropics are not yet cultivated.

In southeastern United States, an important group of soils, the red-yellow podzolic soils, lie between the gray-brown podzolic to the north and the latosols to the south. Like soils farther north, the surface layers are leached and are underlain by horizons rich in clay. But they are not so pervious as the latosols. Thus, when exposed to the rain, they erode easily—far more easily than the latosols. They can be built up to a high state of fertility, yet they share one handicap with the latosols: the soil material holds phosphorous very tightly. C. E. K.

## SOIL CONSERVATION

Soil conservation is the control of soil erosion by water and wind. Jared Eliot of Connecticut wrote the first American work on agriculture in 1748, calling attention to the loss of fertility due to soil erosion. Two generations later, in 1790, Samuel Deane of Maine wrote of wind erosion in a textbook on good farming. The rapid expansion to the West served to prevent the nation as a whole from realizing the great waste of timber and soil.

**Early Efforts Toward Soil Conservation.** The end of the nineteenth century witnessed the first general realization that the era of exploitation and waste of natural resources must end. In 1899, the first soil surveys were begun. In 1901, Theodore Roosevelt took up the campaign for conservation, assisted by the pioneer forester Gifford Pinchot.

*AIRVIEW OF CONTOUR PLOWING IN OKLAHOMA*

COURTESY OF STANDARD OIL CO. (N.J.)

Roosevelt enlisted the interest of the state governors in 1908, and secured action by Congress to protect the shrinking forest areas, mineral lands, and other resources. The U.S. Department of Agriculture and the state agricultural colleges continued to urge soil rehabilitation. In 1929, soil and water experiment stations were set up in ten areas where there were acute problems. In these stations, the methods of controlling erosion were worked out very much as they have been used ever since. The economic crisis of the early 1930's stimulated the organization, in 1933, of the Soil Erosion Service in the Interior Department as a relief measure.

*EXAMPLE OF SOIL CONSERVATION*

*Through the application of the essential soil mineral, phosphorus, and cover crops, the fertility of the field on the left has been restored as compared with the gullied, barren field on the right*

COURTESY OF DEPT. OF CONSERVATION & DEVELOPMENT, NORTH CAROLINA

**Soil Conservation Act.** The Soil Conservation Act, passed by Congress in April 1935, marked the beginning of a comprehensive, nation-wide attack on the problem of saving the soil. The principal advocate of this law was Hugh H. Bennett, a soil scientist in the Bureau of Soils of the Department of Agriculture. Bennett was made head of the new Soil Conservation Service, which was organized in the Department of Agriculture.

**Methods.** The operations of soil conservation include not only contour strip cropping, which has been practiced for thousands of years in most countries, but also terracing, drainage, fertilization, crop rotation, pasture improvement, dam and pond building, planting of woodland shelter belts and windbreaks, and many variations of these operations. *See also* CONSERVATION EDUCATION; DRAINAGE; GEOPHYSICS (*Hydrology*); HORTICULTURE; HYDROLOGY; INDUSTRIES, EXTRACTIVE (*Agriculture*); IRRIGATION; METEOROLOGY (*Climate*); SOILLESS HORTICULTURE. J. C. Ma.

**SOILLESS HORTICULTURE,** a general term applied to the art of growing plants without soil. Three systems or techniques are employed: the solution culture, the sand or gravel culture, and hydroponics.

Solution culture consists of growing plants with their roots immersed in a solution containing all the mineral elements known to be essential for their growth and development. Of the elements known to be necessary for plants, carbon, hydrogen, and oxygen are obtained by the plant from the atmosphere or from water absorbed from the growth medium. Potassium, calcium, magnesium, nitrogen, phosphorus, and sulphur—sometimes designated as the major elements; iron, manganese, boron, zinc, copper, and perhaps molybdenum—frequently referred to as micronutrients, or trace elements—are absorbed from mineral salts dissolved in the water surrounding the roots. Many culture solutions have been devised and are used successfully. One which has been used extensively contains in each liter of distilled water: 0.2 g. $KNO_3$, 0.2 g. $KH_2PO_4$, 0.8 g. $Ca(NO_3)_2 \cdot 4H_2O$, and 0.2 g. $MgSO_4 \cdot 7H_2O$. To this is added 1.0 cc. of a solution of micronutrient salts prepared by dissolving in a liter of water 1.0 g. $FeSO_4$; 1.5 g. $H_3BO_3$; 1.5 g., $MnCl_2 \cdot 4H_2O$; 0.1 g. $ZnCl_2$; 0.06 g. $CuCl_2 \cdot 2H_2O$; and 0.05 g. $MoO_3$. The solution must be renewed at appropriate intervals, either by replacing the old with fresh solution or by a method of continuous flow. Aeration must also be provided.

In sand culture or gravel culture, plants are grown in sand, gravel, or other chemically inert aggregate particles. The inert materials are kept moist by surface applications of the culture solution at suitable intervals. Good drainage is essential. A practical method for large-scale production is that of subirrigation, which requires watertight beds of the aggregate into which the culture solution is pumped from a reservoir at a lower level. After each flooding of the bed to within about an inch from the surface, the solution drains back into the reservoir by gravity. This method provides excellent aeration for the roots and can be made relatively automatic. It is commonly employed for greenhouse production of floricultural and horticultural crops.

Hydroponics is a term applied to a system of soilless culture which combines certain features of both solution and sand culture, and is used for the large-scale production of plants. Seeds or seedlings are planted in a bed of litter such as excelsior, wood shavings, peat, and sphagnum moss, or a mixture of these or similar materials, forming a porous mat supported on a tightly stretched, asphalted wire screen above the culture solution, which is contained in a shallow tank of convenient size. An air space of one or two inches between the solution surface and the porous mat is an important feature of this system. As the plants grow, they send some of their roots into the porous mat, which provides a firm support, while others penetrate into the solution, from which they absorb the inorganic elements necessary for growth. Some means of aerating and circulating the solution in the tank is sometimes necessary to obtain the best results. J. W. S.

**SOIL MECHANICS,** a branch of civil engineering in which the principles of physics and mechanics are applied to engineering design and to analysis of structures supported on or built of soil.

Soil mechanics, as it is currently known, had its actual beginning with the publication in 1925 of the classical *Erdbaumechanik* by Karl Terzaghi, the founder of modern analysis of soil action. The contribution of Terzaghi was a well-organized and realistic correlation of mechanics and empirical knowledge with true physical properties of soils determined by laboratory and field measurements. Within limited fields, this same approach was coincidentally applied by K. E. Petterson and W. Fellenius to earth slides in Sweden, and by D. E. Moran to settlement and foundation problems in the United States.

**Nature of Soils.** Soil, in soil mechanics, includes all material in the earth's crust that is not solid rock. It consists of accumulations of mineral particles from boulders to colloidal clay grains visible only in the electron microscope. The spaces between the mineral grains contain air, water, or both, and, in many surface soils and some other deposits, varying amounts of organic solids. Natural soils are the product of geologic forces of disintegration, transportation, and deposition. They vary widely in physical character with minor variations in the geologic history and processes.

**Classification.** The basic procedure of soil mechanics is to combine physical properties of soils, measured by laboratory or field tests, with stresses or mass forces, computed on a theoretical or semiempirical basis, to determine the action of the soil under, or in, an engineering structure. This procedure leads to a major division of subject matter into (1) physics of soils, and (2) mechanics of soils. Physics of soils is the study of physical properties of soils and methods for their quantitative measurement. It includes properties of individual mineral grains, mass properties for identification and classification of soils, and strength and deformation properties that govern behavior under load. Mechanics of soils is the study of stresses and mass forces in soils in typical engineering problems, utilizing the soil properties from soil physics to determine the safety of the engineering structure and also its performance. Within the mechanics of soils, two general types of soil action are of basic interest to the engineer. The first is actual shear or sliding failure in the soil due to insufficient strength to sustain applied loads. Actions of this type include stability of earth slopes, pressure of earth on retaining walls, ultimate bearing capacity of footings resting on soil, bearing capacity of piles, and all actions generically termed "problems of rupture." The second general type of soil action involves deformations of the soil too great for the supported structure to sustain without failure or improper functioning. It includes settlements of buildings, bridge piers, highway and airfield pavements, etc., and distribution of pressures on walls, tunnels, etc., all termed "problems of deformation." These two general types of soil action are quite independent, since the first involves soil failure while the second involves only deformation or yielding without approaching actual failure of the soil. Therefore, they are treated as separate groups of problems in soil mechanics. There are, in addition, problems in soil mechanics involving neither rupture nor deformations. These include the dynamics of pile driving, the flow of water through soils and analysis of seepage through dams, the production of wells and drainage, the mechanics of quicksand and its effects, and frost action in soils and its effects on highways, airfields, and structures. *See also* Building Construction; Dams; Foundations; Soil. P. C. R.

**SOISSONS** [swa′sõ′], a historic city of the department of Aisne in north central France, situated on the River Aisne about 65 mi. northeast of Paris. During Roman rule it was the chief town of the Suessones. Here in 486 the Romans were defeated by Clovis, King of the Franks. The town became the capital of the West Frankish kingdom of Neustria in 511. Among the chief reminders of its importance during the Middle Ages are the spires and cloisters of the abbey of St. Jean-des-Vignes (damaged by bombardments in World War I), founded in 1076, where Thomas à Becket spent nine years; the church of the abbey of St. Léger, with a crypt of the ninth and tenth centuries; and the remains of the abbey of St. Médard, where Louis the Pious was imprisoned by his sons in 833 and later Abélard was confined. The Cathedral of Notre Dame (partly ruined during World War I) exemplifies the mixed Romanesque and Gothic style of the twelfth and thirteenth centuries; the former church of St. Pierre-au-Parvis, dating from the twelfth, is Romanesque. Soissons is a market for grain, string beans, and sugar beets. The principal industries of Soissons include tire factories, tanneries, foundries, copper works, and other metal-working plants. Pop. 1954, 20,484. W. McE.

**SOISSONS, BATTLE OF** [swa′sõ′], A.D. 486, the first major victory of the Frankish king, Clovis, in which he defeated Syagrius, the last independent Roman administrator in Gaul. The Franks then annexed the territory north of the Loire River and eventually extended their sphere of influence southward. The Battle of Soissons marked the beginning of the rise of the Franks, and the end of the Roman domination of Gaul, which had existed since the time of Julius Caesar. T. B. J.

**SOL** [sɒl], the Roman god of the sun, identified with the Greek Helios. *See also* Helios.

**SOLANUM** [sole′nəm], a large genus of herbs, shrubs, and small trees of the nightshade family, found in temperate and tropical climates. Several species are of economic importance, including the potato, *S. tuberosum,* native probably to the Andes, and the eggplant, *S. melongena,* originally from southwest Asia. Others are of ornamental value, such as the bittersweet, *S. dulcamara,* naturalized in the United States from Europe, and the Jerusalem cherry, *S. pseudocapsicum,* also probably native to Europe. The flowers of this genus are often showy, wheel-shaped, or shallowly bell-shaped in various colors, including yellow, blue, purple, and white. The fruit is a fleshy, many-seeded berry. Some of the genus are climbers, and some are spiny. J. C. Wis.

**SOLAR HOUSE HEATING.** The use of solar energy for heating houses seems quite attractive from several viewpoints. First of all it could reduce substantially the consumption of our dwindling supplies of fossil fuels. This conclusion is supported by studies which show that space heating alone requires nearly 30 per cent of the fuel used annually in the United States. Less industrialized areas of the world devote even larger fractions of their fuel resources to space heating. Secondly, space heating occurs at such low temperatures that the fuel is used very inefficiently. For efficient usage fuel should be burned at a high temperature, 2,500° F. or more, with part of the heat used for power generation and the heat rejected from the prime mover finally utilized for space heating and other low-temperature purposes. Installations to accomplish this sequence are presently found only in ships and central power stations, and

are not regarded as feasible for individual homes or other moderate-sized buildings. Thus, the development of solar heating is of current interest and is the subject of some contemporary research.

The average dwelling house in the U. S. requires heat energy in amounts up to 400,000 B.t.u. per day or more. Studies of weather sequences and of the intensity of solar energy lead to the general conclusions that a solar collector for a dwelling house should have an area facing the sun of from 500 to 800 sq. ft. and that a heat storage unit should be provided with a capacity sufficient for operation during eight to 10 sunless days in succession.

Collectors for heating by solar energy consist of glass-covered black surfaces, oriented so as to receive a maximum of radiation from the sun. The function of the glass cover is to trap the solar energy. The solar energy is initially in the form of short-wave light rays. These rays are absorbed by the black surface, cause it to become hot and, therefore, to re-radiate part of the energy as long-wave infrared rays. The glass has a property which allows the short-wave rays to pass through but does not allow the long-wave rays to pass. Thus, energy accumulates in the enclosure; the temperature of the whole structure rises; the coverglass heats up, and the heat loss from the outside of the structure by convection and radiation approaches equality with the heat entering as short-wave light rays. Temperatures as high as 300° F. may be achieved in small closed structures with insulated bases and no cooling. However, useful application of the solar collector is accomplished by removing heat continuously from the absorber surface and thereby keeping the temperature comparatively low. If the absorber surface is made of metal, the heat may be carried away from it by the circulation of water or air across the plate, generally in metallic ducts or tubes in contact with the absorber plate. In another design the absorber surface is made of black glass strips, spaced away from the inner panel boundary so that air may flow over both sides of the strips and hence promote a high rate of heat flow.

A solar-heated dwelling house was constructed in Dover, Mass. in 1948. The Dover house has a heat collector in the form of a vertical panel 10 ft. high by 72 ft. long, forming the south outer wall of the attic space above the one-story house. The visible rays of the sun pass through the double-glass window panes and are absorbed on the black-painted, metal, rear wall of the collector unit, parallel to the glass panes and a few inches behind them. Air, circulated over the black surface by a fan and a system of baffles, is warmed by contact with the surface. The warm air may be used directly for heating the house during the day time and, at the same time, may be circulated through a heat storage unit to be used to supply heat during the night and sunless hours. The storage unit in the Dover house consists of a bin or closet containing many sealed cans of a chemical, such as sodium sulphate decahydrate, which freezes and melts at 90° F. and releases or absorbs over 100 B.t.u. per pound of chemical. The total weight of the canned chemical is 21 tons and its volume is 470 cu. ft.—small when compared to the total volume of 10,000 cu. ft. for the entire house. This quantity of chemical, when fully "charged" with heat, should provide enough heat for 10 sunless days.

During sunlit hours, air is circulated through the heat collector and the heat storage bin. When the air is warmer than 90° F., heat is transferred to the chemical and causes it to melt. At night, and during other sunless periods, air is circulated through the heat storage bin and the living space of the house, with dampers used to prevent circulation into, or out of, the then cold heat collector unit. When air flowing through the storage bin is colder than 90° F., it collects heat from the melted chemicals. This warms the air and causes the chemicals to solidify again. The Dover house is reported to have been adequately heated by the system during the six years of its history.

Other proposals for solar house heating differ from the Dover house not only in the form of the collector but also in the design of the heat storage unit. Two other experimental buildings have been constructed in the U. S. One, in Cambridge, Mass., used water as a heat transfer medium. It was heated in sunlit hours by passage through coils connected to the absorber panel which was placed behind glass on the sloping south face of the roof. The hot water was stored in an insulated tank placed in the attic. About 20 B.t.u. per day per pound of water could be stored, and the tank was large enough to carry the heating load for five successive sunless days.

Another experimental system was placed in a home in Colorado. It consisted of collector units placed between the rafters on the southern slope of the roof with heat storage provided by a pile of loose gravel placed in an insulated duct. The amount of gravel was sufficient only to provide heat during the night hours and a normal fuel-fired heating system was used on sunless days.

Each of the systems described above is still in the early stages of development. Based on current prices (1955) the cost would be several times that of conventional type heating systems. Solar collector efficiencies are of the order of 50 per cent or less and improvements in this unit alone could reduce costs considerably. Heat storage units need much improvement and will be feasible only if they can be made more compact. E. D. H.

**SOLAR MOTION,** the sun or the entire solar system, moving in space with reference to the nearer stars. This solar motion is at the rate of 12.2 mi./sec. or 4.2 astronomical units per year, and the direction of motion is toward a point in the constellation Hercules, a few degrees from Vega. This point, the apex of the sun's way, is at right ascension $18^h$ and declination $+30°$. The motion is known by the statistics of proper motions of many stars, and independently by their radial velocities. At the apex, the stars are moving toward the earth and slowly separating, while at the opposite point, the solar antapex, in Columba, they are closing in. Motion toward Hercules should not be confused with the sun's motion around the center of the Milky Way at a velocity of 160 mi./sec. *See also* SOLAR SYSTEM. H. S. R.

**SOLAR SYSTEM,** a unit of the universe, consisting of the sun, the nine major planets, their satellites, the minor planets, comets, meteors, and certain aggregates of small particles known as Zodiacal Light. It contains one star, the sun, about which all members of the solar family, except the satellites, revolve at various distances and speeds in accord with Kepler's laws of planetary motion.

One of the greatest scientific controversies of all time was waged over whether the earth or the sun was the center of the universe. Speculation regarding the motion and arrangement of the planetary bodies occupied the entire century and a half following the Renaissance, with two doctrines pervading the thought of this period. One, a direct carry-over from ancient times, was the concept of Aristotle that the earth was the center of the universe, and that all the planets and stars revolved around it. Aristotle's concept, although unchanged in fundamentals, was later modified by

Hipparchus, Ptolemy, and Tycho Brahe, in turn, better to explain certain planetary motions by means of a complex system of deferents and epicycles. The theory of these various authors was called the geocentric theory.

The second basic principle was originally proposed by Aristarchus about 250 B.C. The complete theory was not formally stated until the time of Copernicus, whose great work *De Revolutionibus,* reached him on his deathbed in 1543. This latter (heliocentric) concept—that all objects composing the solar system revolve ultimately around the sun as center—is now considered to be the true one. So strongly was the authority of Aristotle's teachings entrenched in the minds of the people, that it took more than 2,000 yrs. after the original pronouncement of the Aristotelian theory for its final dissolution. The great scientific achievements of Kepler, Galileo, and Newton were instrumental in bringing about this victory over dogma. Both heliocentric and geocentric theories were taught in the earliest American universities, Harvard and Yale, for a number of years.

## SUN

The sun is the center of the solar system and the closest star to the earth. It appears larger and brighter than any of the other stars because of its comparative nearness—a distance of 93 million miles compared with the 25 trillion miles of the next closest star. Physically, the sun is a huge ball of glowing gas and incandescent vapors, with an average surface temperature of approximately 6,000° C. (11,000° F.), increasing to an estimated 10,000,000° C. (or more) deep in the interior.

**Radiant Energy.** The radiant energy of the sun is created by the continuous transmutation of its chemical elements, known as the carbon-cycle, and the energy thus produced is manifest as heat and light. The process responsible for the light of the sun is not one involving actual burning; solar temperatures are well above those at which normal oxygen combustion processes may occur. The radiation of the sun is produced by atomic processes. Streaming outward from the surface of the sun in all directions into space is an enormous quantity of radiant energy, whose continuous outflow results in a reduction in the mass of the sun at the rate of 4,000,000 tons each second.

Assuming the intervening space to be completely transparent, the radiant energy which reaches the outer limits of the earth's atmosphere and falls perpendicularly upon each square inch thereof is only 3/10,000,000,000 of the original energy which leaves the sun's surface. By the loss of as little as five per cent of this incident radiant energy, human life would perish on a frozen terrestrial sphere.

**Size and Appearance.** The sun is 865,370 mi. in diameter; its mass is 333,434 times, and its volume more than 1,000,000 times, that of the earth. In terms of size, mass, temperature, and physical characteristics, it is only an average stellar object. The visible surface of the sun as seen with the aid of very dark glasses or through a considerable depth of fog or smoke is the incandescent layer of solar atmosphere known as the photosphere. This luminous surface reveals a mottled "rice-grain" appearance, with each bright fleck or granule measuring hundreds of miles in diameter. Brilliant patches of luminosity, visible on the solar disk in ordinary light, are known as faculae.

**Sunspots.** Isolated dark areas on the sun, first observed telescopically by Galileo, although known through naked-eye observations by the ancient Chinese, are called sunspots. They are huge whirling vortices in the solar atmosphere, representing zones of intense disturbance. While the temperature within a sunspot is several thousands of degrees, the difference in temperature between the sunspot and the photosphere amounts to about 2,000°, or sufficient to produce a comparative difference in luminosity.

Sunspots follow a definite cycle of occurrence. From the results of observations extending well back into the eighteenth century, it is found that, on the average, spots reach a maximum frequency of occurrence every 11.1 years. At the time of sunspot maximum, the disk of the sun may be covered with spots. At sunspot minimum, weeks may pass without a single spot appearing on the photosphere of the sun. Sunspots move from higher latitudes at the beginning of each

FROM MT. WILSON OBSERVATORY, COURTESY OF AMERICAN MUSEUM OF NATURAL HISTORY

*Direct photograph of sun showing sunspots*

new cycle, to low latitudes as the cycle dies out. The spots almost invariably occur in pairs, or in two separate clusters, possessing opposite magnetic polarity, and acting as huge centers of electromagnetic activity. The polarity of the preceding and following spots of each group is opposite in the northern and southern solar hemisphere, and the polarity of all spots is reversed with a new sunspot cycle.

The sun rotates on its axis in a counterclockwise direction looking down from the north ecliptic pole. The period of rotation is 25 days at the equator, varying to a maximum of 34 days near the sun's pole. This motion of rotation also carries the sunspots across the disk of the sun from east to west with respect to cardinal points on the earth's horizon, so that the same spot is only visible for about two weeks on the earth's side of the sun before it disappears.

*Influence of Sunspots.* Sunspots affect the course of earthly events through physical connection with certain electrical and magnetic phenomena in the earth's atmosphere. These events include displays of the aurora borealis and aurora australis, and short-wave radio fadeouts, both of which are very prevalent at times of sunspot maxima. Statistical correlations between sunspot activity and long-period, climatological changes are possible, but frequency of sunspots, alone, bears no proved relationship to day-to-day weather at any one point on the earth's surface. Chromospheric flares are also seemingly influential in causing short-wave radio fadeouts. As seen in a spectrohelioscope, solar flares resemble the splash

*The corona exhibits characteristic short, brushlike filaments near the sun's poles, and broad, high streamers near its equator.*

of fluid rising around a stone dropped onto a water surface. These flares emit large bursts of ultraviolet radiation, which is ultimately effective in increasing the ionization of the earth's upper atmosphere. A lag period of approximately 26 to 36 hrs. seems to occur quite commonly between the appearance of a sunspot on the sun's central meridian and the occurrence of any electromagnetic effect in the earth's atmosphere. However, the time between the first outbreak of flare activity on the sun and the corresponding radio disturbance on earth is a matter of minutes. This suggests that the cause of the radio fadeout is the influx of ultraviolet radiation traveling with the speed of light, since the "light-time" from the sun to the earth is only eight minutes.

The reason for the direct correlation between radio reception and solar activity lies in the fact that the sun is itself the agent which makes radio transmission possible on the earth. Were it not for the stream of electron particles projected from the sun and continuously entering the earth's upper atmosphere, long-range radio reception would be unknown. The penetration of this electron stream from the sun into the earth's upper atmosphere results in several electrified or ionized layers at levels ranging (during a 24-hr. period) from 30 to 175 mi. above the earth's surface. One of the most significant of these is the Kennelly-Heaviside ($E_1$) layer. This electrically charged layer acts as a barrier to conventional broadcast-band radio signals transmitted from the surface of the earth, which would otherwise proceed unimpeded into space. Due to the "radio roof" imposed by this ionized layer sky-wave radio signals are reflected back toward the earth's surface, and may be picked up by a receiver at a distant point. During the day, with the sun in the sky, the Heaviside layer is depressed to about 70 mi. above the earth's surface by the magnitude of the electron stream, and the range of radio reception is limited. At night, in the absence of the sun, and subject to a diminished electron stream, this layer rises to a point around 100 mi., and radio reception is possible at greater effective distances. Similar relationships, involving different ionization levels, apply to the Appleton ($F$) layer, and short-wave radio reception, where fadeouts are even more pronounced. At times when solar flares are prominent, and near sunspot maxima, the earth's ionospheric layers are distorted, radio signals are affected, and short-wave radio reception may be completely impaired for brief periods. Occasionally, when a particularly large spot or spot-group appears on the side of the sun turned toward the earth, both short- and long-wave radio reception may be marred by static, short-wave radio signals may fade out completely, teletype, land-line, and leased-wire facilities are badly disrupted by garbled transmissions, and even telephone communication is affected.

**Solar Eclipses.** Solar eclipses are produced as the moon, in its revolution around the earth, passes directly between earth and sun, and temporarily obscures the luminous solar disk. The moon's orbit about the earth is inclined approximately 5° to the plane of the earth's orbit about the sun (ecliptic). Accordingly, although the moon reaches a position of alignment with the earth and the sun once each monthly revolution, the moon's position then lies generally above or below the ecliptic plane. It is only at, or near, the points where the moon crosses the ecliptic from south to north, or the reverse, during its revolution, that a total eclipse, either solar or lunar, is possible. For an eclipse to occur, this junction, or nodal point, must also lie along a straight line connecting earth, moon, and sun.

It is possible to have a maximum of five solar, and two lunar, or four solar and three lunar eclipses, in any one year; however, there must be at least two solar eclipses each year. The 18-yr. recurring cycle (19 eclipse years), known as the saros and utilized to determine the time at which the same eclipse will again occur, was known to the ancient Babylonians as early as the sixth century B.C. Theodore von Oppolzer, nineteenth-century Viennese astronomer, employed this relationship to compile a series of tables, the *Canon der Finsternisse*. This monumental work contains data on 8,000 solar and 5,200 lunar eclipses occurring between 1207 B.C. and A.D. 2162.

The sun is approximately 400 times the moon's distance from the earth, but 400 times larger in actual diameter than the moon. Therefore, when viewed in the sky, the sun and the moon have the same apparent dimensions, as seen by the naked eye. When the moon's disk is superimposed upon that of the sun it may completely cover the sun.

A solar eclipse can take place only at time of new moon. As the moon moves in front of the sun, a long narrow shadow cone is projected by the opaque body of the moon, and extends across space toward the earth. The shadow cone cuts a swathe of darkness, averaging about 100 mi. in width, across the earth's surface. The earth's rotation combined with the moon's orbital velocity in the same direction causes the shadow cone to sweep with a speed of 1000 to 5000 mi. per hr. across the continents and seas, the exact speed depending upon the angle of the shadow cone and the horizon.

Complete obscuration of the sun's disk by the moon's opaque body is a total eclipse. Because of the elliptical shape of the moon's orbit, its distance from the earth varies through more than 31,000 mi. at each monthly revolution. The apparent size of the moon's disk, therefore, changes by a slight amount depending upon its distance from the earth. During a solar eclipse that occurs while the moon is at its greatest distance from the earth (apogee) and has its smallest angular diameter, the whole disk of the sun may not be covered by the moon. At this time, a thin ring or "annulus" of light surrounds the lunar sphere, and the eclipse is described as annular. If the moon's position with respect to the ecliptic causes the moon, at maximum eclipse, to obscure only a portion of the sun's disk, a partial solar eclipse results. While a lunar eclipse may last as long as 1 hr. 40 min., the total solar eclipse generally lasts only brief seconds, with a maximum duration of 7 min. 31 sec., when observed under the most favorable conditions at the earth's equator.

In the brief instants of totality, features of remarkable form and color become visible, on and surrounding the solar limb. At the instant of totality, a pearl-white appendage known as the corona flashes into view around the periphery of the sun, and extends many hundreds of thousands of miles above its limb.

As the rays of the sun project over the moon's edge and shine between adjacent highlands, segmented beads of light are often produced by irradiation. Brilliant spots of luminosity known as Baily's beads are then seen on the moon's circumference. When a particularly dazzling point of light blazes forth at a single position on the moon's limb, the illusion of a sparkling diamond set within a narrow band of luminosity is afforded; this singular occurrence is called the diamond ring. Much of scientific value may be obtained from systematic observation of various phenomena during the course of a total solar eclipse.

**Solar Powerhouse.** The sun is a vast powerhouse of atomic energy, possessing extremes of temperature, pressure, and density wholly unattainable in earthly laboratories. Observation of the sun, therefore, provides a means for studying many complex reactions of physics and chemistry under conditions otherwise impossible.

The principal gaseous constituents of the sun's upper atmosphere are hydrogen, the lightest gas known, and helium, the second-lightest chemical element. Also, a rather large number of solid elements are converted by the high temperatures prevailing on the sun into a vapor state. The metallic vapors which exist in relatively great abundance in the solar atmosphere are calcium, iron, magnesium, and nickel. Some 66 of the 98 elements now known on earth have been positively identified in the sun. The third most abundant element is carbon, which represents only a trace compared to hydrogen.

The over-all visible surface or photosphere of the sun as revealed by the aid of a spectrohelioscope is seen to be in a continuous surging motion. This glowing mass of high-pressure gas would give a continuous spectrum by itself. Above the photosphere, and surrounding the sun as a comparatively shallow though indeterminate outer shell, is a semi-transparent layer, the chromosphere. This comparatively cooler gas at lower pressure would give a bright-line spectrum by itself. The base of the chromosphere is sometimes called the reversing-layer, since the superposition of this bright-line source on top of a continuous-spectrum source results in absorption of light in comparable wave-lengths from the continuous spectrum of the photosphere, and the production of the sun's characteristic dark-line or Fraunhofer spectrum.

Projecting upward from the edge of the chromosphere are great tongues of gas and vapor known as solar prominences. At the high temperatures of the chromosphere, the prominences can consist only of clouds of ionized gas, not of flames. Prominences often extend many hundreds of thousands of miles above the sun's limb, and may have internal velocities in excess of 100 mi. per sec. They frequently resemble great feathery plumes on the edge of the sun and, in high-speed motion picture photography, reveal a bewildering composite of motions.

## MOON

The moon (the earth's satellite) is a spheroidal body 2,162 mi. in diameter, or about ¼ the actual diameter of the earth. It revolves around the earth in a period (sidereal) of 27⅓ days, at a mean distance of 238,857 miles. Like all other satellites and planets, the moon shines by reflected light of the sun. Telescopic study is unmarred by the presence of atmosphere or clouds, and the structural details of the moon have been carefully mapped.

**Selenography.** Among the large-scale topographic features are the dark areas named by Galileo lunar "seas" or maria. There is, however, no water on the moon, and the maria are actually vast smooth plains, appearing darker by contrast with the mountainous areas, *Mare Serenitatis, Mare Tranquillitatis, Mare Imbrium, Mare Nubium,* and *Mare Nectaris,* with diameters up to 700 mi., and more, are examples of the Latin designations used. A larger area in the eastern area of the moon is the *Oceanus Procellarum.* Lesser extensions of the maria are known by the designations of *sinus* (bay), *lacus* (lake), and *palus* (marsh).

*DIRECT PHOTOGRAPH OF MOON AT LAST QUARTER*

*The crater* Copernicus, *with diverging rays, is visible near the center of the photograph.* Eratosthenes *lies to the left and below. A curved line, extending from these, passes successively through the large craters,* Archimedes *and* Plato. *The Apennine Mts., 600 mi. long and with peaks 18,000 ft. high, also curve downward to the left from* Eratosthenes. *The lunar Alps merge into the terminator, above and to the left of* Plato. *The darkest area in the upper left portion is the* Mare Nubium, *a vast lunar plain. The Straight Wall, an escarpment 60 mi. long and 900 ft. high, is visible as a thin streak along the left boundary of this plain.*

Crossing the lunar plains are mountain ranges similar to those of earth. Several of these have been named after terrestrial counterparts, such as the Alps, Caucasus, and Apennines. The last-named range is about 600 mi. long and contains more than 3,000 peaks. Its average elevation is 18,000 ft. above the level of *Mare Imbrium.* Other mountain chains close to the limb of the moon, such as the Leibniz Mts., reach as high as 25,000 ft. Isolated peaks are numerous, a typical example being Pico, which rises 8000 ft. above the level of *Mare Imbrium.*

Distributed at random over the surface of the moon are ring-shaped formations known as craters. These range from about 500 ft. to 150 mi. in diameter. More than 32,000 craters are to be seen on the total illuminated disk of the moon visible to earth at full phase. They are sometimes

classified by several types, the largest being called walled plains, the intermediate craters ring plains, and the smallest craters proper. One of the most distinctive craters of the southern hemisphere is Tycho, a ring plain with a diameter of 54 miles. Bright streaks which radiate from the region of certain craters, notably Aristarchus, Aristillus, Copernicus, Euler, Kepler, and Tycho, are called rays. Gorges, cliffs, ravines, and valleys may all be seen as features of the lunar landscape. Other minor features include clefts, rills, and faults, most of which are indistinguishable except with larger telescopes.

Since the moon possesses no atmosphere, it has no means of softening the intense rays of light which stream toward it from the sun. These rays are transformed into heat upon contact with the lunar surface, and the temperature rises to extreme values on the illuminated portions of the moon. In the unlighted hemisphere, and wherever there is shadow, a startling temperature contrast prevails. The same lack of atmosphere also fails to provide a "reservoir" for the storage of heat energy from the sun: there is no "greenhouse effect" such as the earth's atmosphere provides, and heat temporarily absorbed by the lunar surface while exposed to the sun's rays very quickly escapes into space. Through measurements of the albedo of the moon compared with that of terrestrial rocks, it is believed that the surface of the moon is covered with a thin layer of pulverized dust or ash—an equally poor absorber and radiator of heat. Remote instrumental measurements show that at a point on the equator, the surface exposed to the direct overhead rays of the sun attains a temperature in excess of 212° F. When this point moves into an area of shadow, the temperature falls gradually to below —240° F.

The moon is a "dead world": because of the total absence of atmosphere and its related forces of weathering and erosion, the surface remains practically unaltered throughout time, without transporting winds, and even more barren and immutable than the polar wastes of earth.

The moon has an equal sidereal period of rotation and of revolution; it always keeps the same side turned toward the earth, the other side remaining a mystery. However, because of various small motions, known as librations, an observer on earth is permitted to see slightly more than half of the features of the lunar surface during any lunar month.

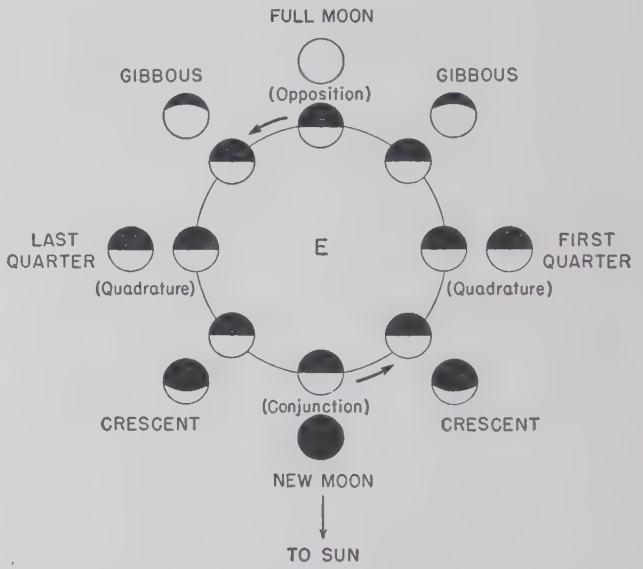
**Phases of the Moon.** Phases of the moon result from the relative positions of earth, moon, and sun. Since the moon shines only by the light received from the sun, except a small quantity of "earthshine" reflected from the earth and visible near the crescent phase, ordinarily only that portion of the moon illuminated by the sun's rays can be seen.

The phases of the moon have nothing to do with the weather, with crop growth, or any of the other superstitions or fallacies so prevalent in everyday literature. The only important influence of the moon on the earth is the physical force entailed in its gravitational pull and tidal action on the ocean waters. The motions and phases of the moon are used as a determining factor in the calculation of dates of church holidays and festivals.

**Lunation.** Lunation is the period of time, averaging approximately 29½ days, which elapses between successive new moons.

**Lunar Eclipses.** Lunar eclipses are produced at full moon, as the moon moves into the shadow cone cast by the earth on the side away from the sun. Once in each synodic revolution of 29½ days, the moon passes behind the earth to a point in a plane with the earth and sun, at time of full moon. The inclination of the moon's orbit with the earth's orbital plane prevents a lunar eclipse at each revolution, for the moon usually passes above or below the earth's shadow. Only when the moon is crossing the ecliptic plane at the same time it reaches alignment with earth and sun is a lunar eclipse possible. The moon then moves directly into the earth's shadow and the reflected sunlight from the moon's surface is extinguished. At total eclipse, the moon does shine, however, with a dull coppery glow, as the rays of the sun, passing laterally through the earth's atmosphere, are refracted into the shadow cone and project a small quantity of light and color upon the moon. The blue rays of sunlight are absorbed by the earth's atmosphere more than the red, and only the latter get through.

Within the shadow cone cast by the earth, two zones of unequal shadow intensity are formed. The innermost and darkest portion is the *umbra,* and the lighter ring of shadow surrounding the central dark core is the *penumbra.* At the



PHASES OF THE MOON

*The inner ring of moons shows position of the moon in its orbit around the earth (E), while the outer ring shows the corresponding phase appearance of the moon as seen from the earth. The arrows along the orbit show the eastward direction of revolution of the moon around the earth.*

average distance of the moon from the earth, the diameter of the umbra cone is about 5,700 mi. The moon travels in its orbit at about 2,300 mi. per hr. The duration of a total lunar eclipse may be therefore, when central, about 1½ hours.

**Lunar Occultations.** A more frequent phenomenon is the occultation of another celestial object. As the moon passes in front of a vastly more distant star, the light from the star is obscured, and the pointlike image is abruptly extinguished. The very suddenness of the disappearance is an observable proof of the absence of any lunar atmosphere; the existence of an atmosphere would cause the star's light to fade gradually. Occultations of a planet by the moon may also occur. Occultations are of value in checking the precise motions of the planets, and of the moon itself.

**Lunar Conditions.** The absence of any atmosphere on the moon precludes the existence of any water there. It also means that, as seen from the moon, the sun and stars would shine from a totally dark sky, free from the light-scattering effects of air particles. Where there is no air to transmit sound, there would be no sound heard by the ear. The lack of atmosphere on the moon is attributable to its low surface gravity, which is a function of the mass of the body. Because

of the smaller size and lesser mass of the moon in comparison with the earth, there exists a correspondingly smaller force of gravity on the moon's surface, approximating only 1/6 that of the earth. Accordingly, an object which on earth weighed 100 lb. would weigh only 17 lb. on the moon.

**Illusions, Superstitions, Phenomena.** *Harvest Moon.* The harvest moon is that full moon which occurs closest to the time of the September equinox. At this time, the full moon rises about the same time for several nights in succession, and this is supposed to provide additional hours in the day for the farmer to harvest his crops before the onset of winter; hence its name. This phenomenon occurs because of the shallow angle between the moon's orbit and the horizon, causing the moon's ascent to be gradual.

*Hunter's Moon.* The next succeeding full moon after the harvest moon, also slow in rising, is termed the hunter's moon, in honor of the appropriate season.

*Wet Moon.* The "wet moon" is purely superstition, it being originally supposed in legend that when the crescent moon was horizontal, with the horns upright, it would hold much water; if the moon was nearly vertical, and the horns sharply tipped, a dry season was indicated.

*Blue Moon.* The "blue moon" is a comparatively rare meteorological manifestation having its basis in physical fact —the selective scattering and absorption properties of small particles for light-rays.

*Others.* The adage of the "old moon in the new moon's arms" or "the old moon sitting in the lap of the new" is a popular phrase used to indicate the moon's appearance as seen shortly after new moon. The formerly invisible portion of the old moon is dimly illuminated by earthshine reflected from earth back onto the moon, and is seen couched in the brightly lit crescent of the waxing new moon.

The phenomenon by which the apparent disk of the moon is made larger when seen in the zenith than when on the horizon, due to the fact that the observer is 4,000 mi. nearer to the moon when it is directly overhead, is known as augmentation. This physical paradox is in direct contrast to the optical illusion by which the moon seems larger when seen near the horizon, an appearance which is produced by physiological response within the eye. The apparent elliptical shape of the moon (and sun) when seen near the horizon is caused by differential atmospheric refraction.

## PLANETS

A planet is one of a number of great, solid spheroids, shining by reflected solar light and circling forever in orbits around the sun. Going outward from the sun, the major planets, in order, are: the inferior planets, Mercury and Venus; the Earth; and the superior planets, Mars, Jupiter, Saturn, Uranus, Neptune, and Pluto. The orbits of the inferior planets lie within the earth's orbit, and the orbits of the superior planets are outside the earth's.

To the unaided eye, the planets look like stars, but in the telescope they appear as disks; whereas the stars are always points of light. Mercury, Venus, Mars, Jupiter, and Saturn were known to the ancients, while the others have been discovered in modern times. Planets are exceedingly small, compared to the enormous distances separating them. They all revolve around the sun in the same direction—counterclockwise, looking down from the north ecliptic pole. Mercury and Venus present moon's phases to observers on the earth but the superior planets show mostly the full phase.

Mercury, Venus, and Mars are dense planets, resembling the earth physically in many ways. Except for Pluto and Mars, the other outer planets show various dissimilarities with the inner planets, being much larger and less dense. Besides the major planets, there are thousands of minor planets, or asteroids, whose orbits are chiefly but not entirely confined to the zone between the orbits of Mars and Jupiter.

The sun, having a large part of the mass of the solar system, is the central dominating figure controlling the motions of all of the planets, and Jupiter, the largest planet, is next in gravitational control. The planes of the orbits of the major planets nearly coincide with the ecliptic plane, except that Mercury's is inclined 7° and Pluto's 17° to the ecliptic; the minor planets have inclinations up to 43°.

As seen from the earth, the inferior planets pass successively through inferior conjunction with the sun, western elongation, superior conjunction, eastern elongation, and inferior conjunction; the superior planets pass through conjunction, western quadrature, opposition, eastern quadrature, and conjunction. The predicted daily positions of planets are given in the national ephemerides. The regular or forward apparent motion of the planets is eastward among the stars, but during part of the year they are seen to move in a western or retrograde direction. The latter effect is caused by the relative orbital motions of the planet and the earth.

A planet may be distinguished from a star by the following tests: (1) Mercury, Venus, Mars, Jupiter, and Saturn possess great brightness. All of them under favorable conditions, outshine the stars; and among them only the luminosity of Saturn is exceeded by that of the brightest star, Sirius. Uranus, Neptune, and Pluto are faint objects. (2) All of the planets appear to move with respect to the stars. (3) Unless close to the horizon, a planet, which possesses a finite reflecting surface, usually shines with a much steadier light than the stars, which appear to twinkle due to interference patterns produced, in radiation from a point-source, by the earth's atmosphere.

**Mercury.** Mercury is the smallest of the nine planets, and revolves nearest to the sun. This planet is only 3,100 mi. in diameter, and is therefore exceeded in size by several of the satellites of the solar system. Mercury requires only 88 days to complete its revolution, so that it passes through four of its years in one terrestrial year. Its rapid apparent movement in the sky caused the planet to be associated in Roman mythology with the name of the wing-footed messenger of the gods; the Greek equivalent was Hermes. At an average distance of only 36,000,000 mi. from the sun, Mercury attains a surface temperature above the melting point of lead, or about 770° F. Since its period of rotation is the same as its revolution, Mercury always keeps the same side toward the sun, although presenting all sides successively to the earth. The side turned toward the sun is constantly subject to tremendous heat, while the opposite, dark side approximates the cold of outer space. Any portion of the illuminated surface of Mercury receives nearly seven times as much light and heat as a similar position on the earth. Mercury's closest approach to the earth is 50,000,000 miles.

**Venus.** Venus completes a circuit of its orbit once every 225 days. Venus is the sister planet of the earth, having a diameter of 7,575 mi. and possessing several other factors of similarity. Called Aphrodite by the Greeks, and Venus by the Romans, after the goddess of beauty, it is the brightest planet. At an average distance of 67,270,000 mi. from the sun, it receives twice as much light and heat energy as the earth. The planet may be seen by the unaided eye in broad daylight, if its direction is known. At maximum brilliancy, it is twelve times brighter than the brightest star, Sirius. At its closest approach to the earth, Venus is within 26,000,000 miles. Recent investigations show that the ro-

tation period of Venus must be several weeks, although less than 225 days.

**Mars.** Mars is important in connection with the contributions to science of the Danish astronomer, Tycho Brahe. His precise observations of Mars' positions largely provided the material upon which the theoretical calculations and important astronomical laws of Kepler and Newton were subsequently based. Almost paradoxically, in the realm of future knowledge, Mars also occupies first place in the imagination of those who envision the conquest of space. Telescopic study of this planet, its surface markings, and of possibilities of life has been a part of observatory work-programs by such careful investigators as Schiaparelli, Flammarion, Lowell, W. H. Pickering, Douglass, Antoniadi, Lampland, V. M. and E. C. Slipher, and Kuiper.

Mars measures 4,268 mi. in equatorial diameter, or slightly over one-half the size of the earth. At its greatest magnitude (−2.8), it appears brighter than any star except the sun and outshines all of the planets with the exception of Venus.

The comparatively large eccentricity of Mars' orbit causes the distance of this planet from the earth to vary between 35,000,000 and 63,000,000 mi. at opposition times alone.

Seen through a large telescope and under ideal atmospheric conditions, the surface of Mars reveals many markings, permanent and transient. Foremost of these surface features are the Martian polar caps. Usually only one fully-developed cap is visible. This brilliant white area may be observed surrounding either the north or south pole, during the appropriate Martian season. Since the Martian year contains 687 terrestrial days, its seasons are almost twice as long as the earthly seasons, and at a distance of 1.5 times the earth's

Note the greater equatorial diameter as compared with the polar diameter, resulting from the high rotational speed of this planet.*

distance from the sun, all seasons are considerably colder. The rotation period of Mars is slightly more than 24½ hrs.

Spectroscopic analysis of the atmosphere of Mars has shown that the amount of free oxygen present cannot exceed 1/1000 by volume of that existing in the atmosphere of the earth. No methane, ammonia, or nitric oxid have been detected in Mars' atmosphere. Similar studies likewise preclude the existence of water vapor in amount over 3 per cent of that found in the atmosphere of the earth. This does not rule out the possibility of even more minute quantities of water being sustained in vapor form by the Martian atmosphere. The atmosphere is about 60 mi. deep, though of extremely small density. Due to lower surface gravity, the atmospheric density does not decrease as rapidly with elevation above the surface as it does on earth, nor will the temperature-drop with increasing altitude be as severe.

*Satellites of Mars.* Mars is accompanied in its revolution around the sun by two satellites, Deimos and Phobos, fragments of rock only an estimated 5 and 10 mi. in diameter, respectively, and visible only in the largest telescopes. The revolution of Phobos is unique in the solar system in being less than one-third the rotation period of its planet.

**Jupiter.** Jupiter, the largest planet, is the fifth in order of distance from the sun and, next to Venus, is usually the brightest planet. It measures 89,329 mi. in equatorial diameter.

Jupiter revolves around the sun in a period equal to almost 12 terrestrial years, at an average distance of 483,900,000 miles. Because of this great distance and the small quantity of sunlight received, the maximum temperature at the surface is −216° F. Its closest approach to the earth brings it within 367,000,000 miles.

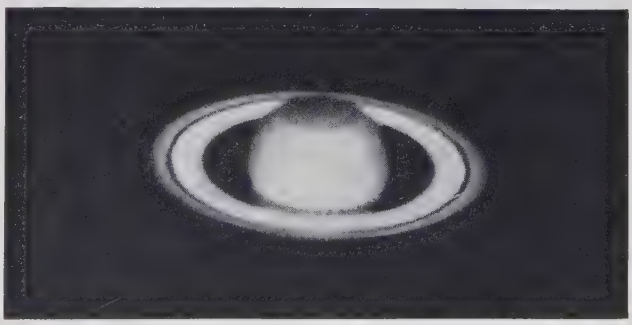
This planet is surrounded by a deep blanket of atmosphere, composed principally of methane, frozen crystals of ammonia, and ammonia vapor. An abundance of free hydrogen is also present. This atmosphere is believed to extend to a height of 8,000 mi. above a thick layer of ice which overlies a rock core. The period of rotation of Jupiter is only 9 hr., 50 min. at the equator, although, due to its predominantly gaseous composition, the period increases toward higher latitudes.

*Satellites of Jupiter.* Jupiter has 12 known satellites. The four largest and brightest moons (Io, Europa, Ganymede, and Callisto) are known as the Galilean satellites in honor of their discoverer, Galileo Galilei. One other fainter satellite lies closer to the primary. Io, Ganymede, and Callisto are all equal to, or larger than, the earth's moon. The last two are more than 3,200 mi. in diameter—larger than Mercury. All four may be seen easily through binoculars. They may all appear on one side of the planet, or be separated by the primary. Not all four moons are necessarily visible at the same time.

**Saturn.** Saturn is the sixth planet from the sun and, with its equatorial diameter of 75,021 mi. constitutes the second largest planet in the solar system: 734 bodies the size of the earth could be packed within its bulk.

To the unaided eye, the yellowish starlike image of Saturn presents no aspect of unusual nature, aside from its luminosity, which is greater than that of any of the stars except Sirius. As seen through a telescope, however, Saturn is the most picturesque planetary object in the sky. It then appears as a shining central sphere, girdled by a remarkable flat, ribbonlike ring. Upon closer inspection, this is revealed to be a complex ring system of several concentric and variously shaded parts. The ring system of Saturn is unique among planets of the solar system.

Saturn exhibits a thick, outer envelope of atmosphere, with an estimated depth of 16,000 miles. This is assumed to overlie a comparatively thin mantle of ice which, in turn, surrounds a solid core of metallic rock. This great depth of atmosphere accounts for Saturn's low density. No perceptible cloud markings such as exhibited by Mars appear on the disk of Saturn, though cloud bands, parallel to the planet's equator, and occasional spots, do occur. Only the gaseous upper layers of atmosphere have ever been seen, and these obscure whatever true surface lies below. By instrumental analysis, the atmosphere of Saturn is found to be composed principally of methane and ammonia, with some hydrogen, also. Methane, here, bears a relatively greater proportion to ammonia than that found in the atmosphere of Jupiter.



COURTESY OF LICK OBSERVATORY

*SATURN AND ITS RINGS*

*The ring system lies in the plane of the planet's equator. The over-all diameter of the planet and its rings is 172,600 mi., with the inner edge of the ring system 6,000 mi. from the surface of the planet. The vertical thickness of the rings is less than 10 mi. The various concentric rings are composed of minute solid particles. The dark band of Cassini's division, 2,200 mi. wide, is a gap between adjacent rings. The shadow of the planet cast on the rings can be seen just above the planet's pole on the ring surface.*

This planet is over 800,000,000 mi. distant from the sun, even at its closest approach and, hence, receives very little light and heat. Measurements of the temperature at the surface show this to reach a maximum of −243° F.—sufficient to freeze portions of the gaseous atmosphere to a liquid or solid state. During its orbital revolution, Saturn reaches a minimum distance from the earth of about 745,000,000 miles. Its year is equal to 29½ terrestrial years. Saturn rotates in a period of slightly more than ten terrestrial hours, so that its day is less than half that on earth.

*Satellites of Saturn.* Nine satellites revolve around Saturn, the largest being Titan, 3,550 miles in diameter, the largest satellite in the solar system. These satellites revolve around the planet in periods ranging from a little less than one terrestrial day to 1½ years, depending upon their distances from the planet. The outermost satellite, Phoebe, revolves with a retrograde motion.

*Ring System.* The ring system of Saturn is composed of myriads of small particles, each revolving in a separate orbit about the planet. It is thought that these countless fine fragments may be the remains of yet another moon, which at some time in the remote astronomical past came within a zone known as *Roche's limit* (a theoretical distance equal to 2.45 times the radius of the planet). Conflicting gravitational forces acting from opposite portions of the sphere tore the original moon (moving into too-close proximity to the body of the planet) apart, distributing the resultant fragments along the present plane. The extremely fine particles composing the ring are in no way structurally connected, but held together in this formation by their common bonds of gravitational attraction, and by that of the planet. The fact that the inner edge of the ring system revolves more swiftly than the outer edge is observational proof of its discrete, small-particle nature.

**Uranus.** Uranus was the first of the outer planets not known to the ancient peoples, whose discovery was made possible by telescopic means. On the night of March 13, 1781, William Herschel, surveying the sky with a seven-inch reflecting telescope, came upon a greenish object showing a perceptible disk, for which no designation was given on existing star maps. Continuing to observe the object, he noted that it possessed a slow movement among the stars. It was at first assumed to be a comet, but later observation and calculation proved it to be of planetary nature. In accord with the tradition of naming the major planets after mythological deities, the name "Uranus," from the Greek god of the heavens, was adopted.

Uranus is a massive planet, 33,219 mi. in diameter, with a volume sufficient to contain 64 objects the size of the earth. It is usually just at, or below, the limit of naked-eye visibility. This planet requires 84 terrestrial years to revolve once around the sun. It is at an average distance of almost two billion miles from the sun, and its surface temperature reaches a maximum of only −300° F. It makes a complete rotation in 10 hrs., 42 min. The composition of its atmosphere is almost entirely methane.

*Satellites of Uranus.* Uranus has five satellites, the fifth and innermost being discovered as recently as 1948. Uranus presents a very curious anomaly in the otherwise orderly pattern of the solar system. The polar axis is tipped almost into the plane of the ecliptic, so that its satellites appear from the earth to revolve almost in a north-south plane. Due to this large inclination of the rotational axis of Uranus, the revolution of all of its satellites is apparently retrograde, although each actually revolves in the same direction as the planet's rotation.

**Neptune.** Neptune is very nearly 3 billion miles from the sun, and requires 165 terrestrial years to complete one revolution. In size and general aspects, Neptune forms a twin of Uranus. It has two satellites, the second being discovered in 1949. At its distance from the sun, Neptune receives only 1/900 of the light and heat received at the surface of the earth, and its surface temperature never rises above —330° F. Its atmosphere is predominantly methane. The period of rotation is approximately 15 hrs.

**Pluto.** Pluto requires 248 yrs. to complete one revolution. At an average distance of almost four billion miles from the sun, it receives only an insignificant fraction of the light and heat which fall upon the earth. It is obvious that Pluto is therefore eternally dark and frigidly cold. It shows little more than a starlike point of light in the largest telescopes. Pluto has an unusually elliptical orbit, at perihelion coming within 2.8 billion miles of the sun, within Neptune's mean distance, and at aphelion receding to a distance of 4.6 billion miles. It has the highest orbital inclination (17°) of any major planet. Its diameter has been measured as 3,600 mi., but its rotation period is unknown. The name Pluto was appropriately chosen, since Pluto was the Greek god of darkness.

## MINOR PLANETS

Minor planets are so-named because of their small dimensions in comparison with the major planets. Like the major planets, these small objects shine by reflected light from the sun, and each pursues a separate orbit around the sun. They are often called asteroids from their resemblance to star-like images in the telescope. Not many minor planets are large enough to show a perceptible disk. One (Vesta), at opposition, is barely visible to the unaided eye. The large gap between the orbits of Mars and Jupiter is the predominant zone of occurrence for the minor planets, which range from a fraction of a mile to several hundred miles in size. The inclinations, eccentricities, and orientations of their orbits vary widely. Minor planets would appear to be the fragments of a major planet that failed to materialize, or that somehow disintegrated, leaving thousands of small pieces in its stead. It has been estimated that fully 50,000 of these objects could be detected by systematic observation with the largest telescopes; yet, the volume of all the known asteroids put together is much less than that of the moon.

The first discovery of a minor planet (Ceres) was made by the astronomer Piazzi. Ceres was followed later by Pallas, Juno, and Vesta. These remained, for 40 years, the only asteroids known. But with the development of astronomical photography in the late nineteenth century, it was not long before hundreds of small planets were found.

Newly discovered asteroids are given a provisional year-designation until their separate identity is proved, and are then serially numbered. So numerous are the minor planets (over 1,500 are now well known), that it is difficult to keep up with all of their changing positions, although the orbit for each, and the disturbances due to the gravitational influence of the major planets, are determined as soon as possible.

Asteroid 433 Eros, which several times has returned to close proximity to earth and sun, has been used for establishing a more accurate value of the astronomical unit. Through the co-operation of world-wide observatories, a campaign for systematic observation of this minor planet has resulted in a very much more accurate determination of this basic value. In 1931, Eros came within 16,000,000 mi. of the earth. Eros exhibits remarkable variations in brightness within the course of a few hours, indicating a rapid rotation and unequal reflecting surfaces; likely, its shape is irregular.

Other minor planets making close approaches to the earth are Amor, Apollo, Adonis, and objects discovered recently by Wirtanen and Baade; and on Oct. 30, 1937, a rapidly moving asteroid approached the earth within a distance of approximately 475,000 miles. At maximum speed this object moved 5° per hour across the sky. The little planet was estimated to be about ¾ mi. in diameter; its calculated period was two years. So rapidly was the body moving, and so few observations were obtained, that existing orbit methods failed; the asteroid was lost; and has never been re-discovered. The object was known provisionally as the Reinmuth Object (1937 UB) after the name of its discoverer, Dr. Karl Reinmuth of Heidelberg. Later, in recognition of its fast movement, it was assigned the name Hermes, after the fleet-footed messenger of the Greek gods. Hermes has the record for the nearest approach to the earth. *See also* AURORA BOREALIS AND AURORA AUSTRALIS; COMETS; EARTH, THE; EPHEMERIS; KEPLER'S LAWS; METEORITES; METEORS; ORBIT; SOLAR MOTION; ZODIACAL LIGHT. **SOLAR TIME.** *See* TIME.

**SOLE,** *Solea solea,* a highly prized European food fish, of the family Soleidae. The sole is a flat fish with the color and eyes on the right side. The jaws and teeth are rather feeble. Other species of sole are found in temperate regions. It is commonly taken in shoal waters in the English Channel and Irish Sea; also it is found in the Mediterranean and the North Sea. It burrows into the sand and rarely moves except at night when it searches the bottom for food. When foraging, it touches the bottom with the side of the head which is supplied with small tactile filaments. Soles attain a length of 26 in. and weight of 9 lb. As in other flatfishes, the eyes of the sole are normally placed when newly hatched but the left eye migrates to the right side when the sole is 6 days old and less than one-half inch in length. In the American market, any one of several other flatfishes, such as flounder, plaice, fluke, and halibut, is frequently sold as sole. E. C. R.

**SOLEDAD PINE** or **TORREY PINE** [sɒ′ləd], a tree, *Pinus torreyana,* found native only in a restricted area near San Diego, California, and on islands off the Southern California coast. In the wild, it is a small, twisted tree, but under cultivation in good soil it will grow over 90 ft. high and may develop a spread of over 100 ft. The needles are in bundles of 5, grayish-green in color, and as long as 5 in. L. deF.

**SOLENODON** [soli′nodɒn], a genus of the mammalian order Insectivora. Two species, *S. paradoxus* and *S. cubanus,* from Haiti and Cuba, are the only representatives of the family. The latter may have become extinct. The animal is somewhat larger than a gray squirrel, has a prominent cylindrical snout, a long naked tail, and coarse fur. The foreclaws are stout and adapted for digging. The solenodon lives in rocky forests in mountainous areas. These animals are of interest to the zoologist because of the wide geographic separation which exists between them and their nearest relatives, the tenrecs of Madagascar. W. J. Ha.

**SOLENT** [so′lənt], a strait in the English Channel between Hampshire and the Isle of Wight. It terminates at the anchorage of Spithead and has a total length of 7 mi., and a width varying from 2 to 5 mi. Two bars projecting into the Solent at Southampton and at the western end are sites of the famous Tudor castles, Hurst and Calshot. The Isle of Wight causes a division of the tidal waters. S. Van V.

**SOLFEGGIO** [sɒlfɛ′jo], primarily a vocal exercise used either for training the voice or for practice in sight singing. The exercise may employ either syllables of solmization or plain vowels. Solfeggi originally used only solmization syllables, which also served as elementary instruction in interval recognition. Exercises on pure vowels were originally called *vocalizzi.* Vocal exercises without text for such uses have been composed by famous voice teachers and composers since the seventeenth century.

By extension, the term *solfeggio* has been applied to general courses in the rudiments of music, including the study of intervals, rhythm, scale structure, clefs, and notation. *See also* SOLMIZATION. F. C. C.

**SOLFERINO, BATTLE OF** [sɒlfəri′no], fought on June 24, 1859, the decisive engagement of the Austro-Sardinian War of 1859. After successive defeats administered to the Austrians by the French, command of the Austrian army was taken by Emperor Franz Josef. The Austrians had retired over the Mincio River after the Battle of Melegnano, though they still held a bridgehead over the river. Early on June 24, both armies planned to take the offensive and accidentally encountered each other. While the Emperor ordered his main body back over the Mincio, the French under MacMahon were advancing to occupy the left bank of the river. Contact was made at 8 A.M. on a limited front which soon stretched out to one of over ten miles. The French and Sardinians made slow headway against the Austrian line from Rebecco to Cavriana and thence north to Solferino, which was stormed and taken by the French guards. The fighting, with varying results, continued until late in the afternoon. About 4 P.M., in the midst of a thunderstorm, the Austrian commander ordered a retreat, leaving a covering force to protect the withdrawal. The Sardinians attacked in force and, lacking support or re-enforcement, the Austrians withdrew across the Mincio River, having lost 22,000 men, the Allies 17,000. On July 11, 1859, Napoleon III and Franz Josef signed the peace of Villafranca and hostilities ended. M. K.

**SOLIDS AND LIQUIDS, THEORY OF.** There are three easily distinguishable types of aggregation in which the atoms of matter may exist: the gaseous, liquid, and solid states of matter. Gases are characterized by the properties of large compressibility and small density, whereas solids and liquids possess small compressibility and relatively large density. Under normal conditions of temperature and pressure, the mass of a unit volume of a gas is of the order of a thousandth of that of a typical solid or liquid. The great compressibility of a gas results in the property it possesses of filling completely a container in which it is confined. This property is sometimes referred to by stating that a gas has no definite volume. A solid has a volume which changes little with change in pressure, and also a definite form. Liquids are like gases in that they cannot support shearing stresses and adapt their form to that of the containing vessel. Liquids are similar to solids, however, because of their small compressibility, their volume depending to only a slight extent on external conditions.

The differences in the physical properties of gases and solids can be understood if it is assumed that the atoms are separated by much larger distances in gases than they are in solids or liquids. Since there are relatively few atoms in a unit volume of a gas, the density is small; and since the atoms are separated by relatively large distances, the interatomic forces

are weak and it is easy to change the interatomic spacing. The theory of gases is much simpler than that of solids and liquids, because the atoms of a gas are widely separated and the forces acting between them are weak. An adequate theory of gases can be constructed by ignoring the interatomic forces completely and considering only the motion of the atoms. This procedure cannot be adopted in developing a theory of solids and liquids, in which the interatomic forces must be explicitly considered, because the atoms are close together and the forces between them are very powerful. Since there are several types of interatomic forces, the properties of solids and liquids show more variety than those of gases. The properties of mercury and argon, for example, are very similar when these substances are in the gaseous state but quite different when they are in the liquid and solid states.

## THE SOLID STATE

Solids are commonly classified according to the type of attractive force which is predominantly responsible for the cohesion of the atoms. In the following discussion of attractive forces this convenient classification of solids into ionic crystals, valence crystals, metals, and molecular crystals is followed.

**Ionic Crystals.** It has been determined that an electron can be rather easily removed from a sodium atom and that an atom of chlorine tends to add an electron to itself. By these means, the atoms assume the stable configurations of the rare-gas atoms neon and argon, respectively. The process of transfer of an electron from a sodium atom to a chlorine atom will take place if the atoms come into contact with each other. After the transfer of the electron, each atom is electrically charged, and is then referred to as an ion. The positively charged sodium ion and the negatively charged chlorine ion will attract each other with the well-known electrostatic Coulomb force, which is directly proportional to the product of the charges of the ions and inversely proportional to the square of the distance between them. Under the influence of this attractive force, the ions will approach each other until their closed shells begin to interpenetrate. The closed-shell repulsive force will then suddenly increase, and the two atoms will remain at the equilibrium distance of separation at which the attractive Coulomb force is just balanced by the repulsive force.

The same forces that act on one ion of sodium and one of chlorine also affect a mixture of large and equal numbers of ions of each kind. Each sodium ion will tend to surround itself with chlorine ions, and each chlorine ion will tend to surround itself with sodium ions. The sodium ions will repel each other, as will the chlorine ions also, since the Coulomb force of electrostatics is one of repulsion between ions of like sign of charge. The result of the interplay of forces between the ions is a coalescence of the ions to form a crystal. The technique of X-ray diffraction reveals crystal structures such as this and allows the interatomic distances to be measured with great precision. There is a definite symmetry to the structure—that of a cubic lattice. Each sodium ion has six chlorine ions as its nearest neighbors, and each chlorine ion has six sodium ions for neighbors. Structures of this or very similar type are characteristic of ionic crystals where the attractive force is nondirectional and the ions are spherically symmetric.

Since the formation of ions by transfer of electrons from atoms of one type to atoms of another type is necessary if the Coulomb force of attraction is to exist, ionic crystals are formed by the combination of elements from opposite ends of the periodic table of the chemical elements. One of the elements must be electropositive in character, each of its atoms having lost one or more electrons to the atoms of the other element, which must be electronegative in character. The most typical ionic crystals are therefore alkali halide compounds, such as lithium fluoride, sodium chloride, and potassium bromide. Also strongly ionic in character are the oxides of the alkaline-earth metals, such as calcium oxide and magnesium oxide.

Since ionic crystals are formed of positively and negatively charged ions, if the resulting crystal is to be electrically neutral, there must be equal numbers of each type of ion present if the ions are equally charged. In an ionic solid such as magnesium fluoride, the number of fluorine ions must be just double the number of magnesium ions, since each magnesium atom has lost two electrons and each fluorine atom has gained one. Therefore ionic crystals obey the chemical laws of definite composition and of combining weights very exactly.

**Valence Crystals.** The salient features of the homopolar bond which provides the attractive force binding atoms together in valence crystals can be displayed by considering the behavior of two hydrogen atoms which are interacting with each other.

As two hydrogen atoms approach each other it cannot be expected that there will be a permanent transfer of electrical charge from one to the other, because they are identical in their structure. Yet, each will attempt to add an electron to its structure so that it may achieve the stability of the helium atom with its closed shell of two electrons. The compromise reached by the two atoms consists of a sharing of their electrons with each other. The two electrons which are shared between the atoms spend the major fraction of the time between the nuclei of the atoms. In order that this electron-pair bond may be formed, an important condition must be met. An electron behaves like a small magnet, and the axes of the magnetic moments of the two electrons must point in opposite directions if they are to form a homopolar bond. An electron's property of behaving like a magnet is usually referred to as a result of electron spin. The condition of antiparallel spins, which is demanded by the fundamental principles of quantum mechanics if the electron-pair bond is to form, gives this bond the property of saturation. Two hydrogen atoms may unite to form a molecule by using their electrons to form an electron-pair bond. A third hydrogen atom cannot be added to the diatomic molecule, however, because of necessity the spin of its electron will be parallel to the spin of one of the two electrons in the molecule. For this reason, hydrogen atoms cannot make use of the valence or electron-pair bond to form a crystal composed of many hydrogen atoms. As an example of a crystal in which the atoms are held together by valence forces it is necessary to turn to the diamond.

The carbon atom has the property of possessing four electrons in an unfilled shell. By adding four more electrons to its structure, it is able to imitate the stable structure of neon. In the diamond crystal, each carbon atom shares its four electrons with four other carbon atoms, thereby forming four electron-pair bonds with four other atoms. In this manner an indefinitely large array of carbon atoms may be joined together to form a crystal.

The magnitude of the attractive force between atoms which have formed an electron-pair bond is large. As a result, the work that must be performed to separate the atoms of a valence crystal from each other is large. The heats of sublimation of typical crystals as shown in the table are a direct measure of the work necessary to separate the atoms or ions of the crystal from each other. It will be noticed that the values for valence crystals are of the same order of magnitude as those

for ionic crystals. Another result of the strength of the valence bond is that the melting points of valence crystals are high, even higher than those of ionic crystals.

HEATS OF SUBLIMATION OF SOLIDS
*(Kilogram-Calories per Mol)*

| *Ionic Crystals* | | *Valence Crystals* | | *Metals* | | *Molecular Crystals* | |
|---|---|---|---|---|---|---|---|
| NaCl | 153.1 | Diamond | 170. | Na | 25.9 | Helium | 0.052 |
| KCl | 153.1 | Boron | 115. | Cu | 81.2 | Neon | 0.52 |
| NaBr | 139.5 | Silicon | 85. | Ca | 47.8 | Argon | 1.77 |
| KBr | 140.8 | Germanium | 85. | Zn | 27.4 | Hydrogen | 2.44 |
| NaI | 120.8 | SiC | 283. | Al | 55. | Oxygen | 1.74 |
| KI | 124.3 | $SiO_2$ | 405.7 | Fe | 94. | Nitrogen | 1.50 |
| | | | | Pt | 127. | | |

**Metals.** The majority of the chemical elements exist in the solid state in the form known as metals. The characteristic feature of metals is their electrical conductivity. The attractive force which binds the atoms together in metals is very similar in nature to that existing between atoms in valence crystals. There are certain peculiarities of the homopolar bond between atoms in metals which give to metals quite different properties than those of valence crystals. The cause of the special character of the homopolar bond in metals lies in the fact that the atoms which form metal crystals are always electropositive, tending to lose electrons and form rare-gas structures of closed shells. When these atoms unite by forming homopolar bonds with each other, the shared electrons are not localized as they are in the bonds formed between atoms in valence crystals. It cannot be said that any two of the valence electrons are co-operating to bind together a particular pair of atoms. The electrons forming the homopolar bonds are free to roam the interior of the metal—a condition which results from the fact that these electrons were very weakly bound to individual atoms before the formation of the homopolar bonds.

An immediate consequence of the freedom of motion of the valence electrons in metals is the large electrical conductivity. A second consequence is that the homopolar bond in metals is not directional in character, and the crystal structures thus tend to be simple and similar to those of ionic crystals where the Coulomb force is also nondirectional. Unlike ionic compounds, the metals have little tendency to obey the law of definite composition, because the atoms are uncharged. In general, two metallic elements can be alloyed in any proportions and do not form a compound of specific composition. When they do form such a compound, it is because one element is sufficiently more electropositive than the other that there is a permanent transfer of charge between the atoms. Under these circumstances, the attractive force between the atoms is partially ionic in origin. The rather small heats of sublimation of typical metals shown in the preceding table indicate that the homopolar bond in metals is considerably weaker than it is in valence crystals.

**Molecular Crystals.** The atoms of rare gases such as helium and neon are unique in that the number of electrons possessed by each is such as to allow the formation of the most stable possible atomic structure. One would not expect these atoms to form homopolar bonds with each other or with other atoms. Neither would the formation of ions by the gain or loss of electrons be expected to occur, since this process would lead to the formation of less stable structures. At low temperatures the rare gases do condense, however, to form liquids and, except in the case of helium, solids.

The explanation of the attractive forces between atoms of the rare gas type is as follows: Although the electrons are arranged in closed shells having spherical symmetry on the average, the motion of the electrons leads to small fluctuating deviations from complete spherical symmetry. These small fluctuations from a spherically symmetric distribution of the electronic charge give the atom a fluctuating electric dipole moment. Another atom exposed to the rapidly varying dipole field of the first atom will have the motion of its electrons slightly altered. The dipole moment of this second atom tends to change in synchronism with that of the first atom, and the directions of the dipole moments are such that there is on the average a net force attracting the atoms to each other. It can be easily shown that this weak dipole-dipole or van der Waals' force varies as the inverse seventh power of the interatomic separation.

Many molecules, of which the hydrogen molecule is an example, condense to form liquids and solids because of these dipole-dipole forces between them. That this binding force is very weak is shown by the low melting and boiling points of these substances and their extremely small heats of sublimation. Among the vast class of organic compounds, the forces binding the atoms together to form molecules are predominantly homopolar in type, but the complex molecules are bound together to form solids and liquids by the relatively weak van der Waals' forces. The result is that most organic compounds have low melting and boiling points and small heats of sublimation.

### THERMAL MOTION OF THE ATOMS

A theory of a solid as an assemblage of atoms rigidly bound together by the action of attractive and repulsive forces is an oversimplified static representation. A more correct model of a solid is a dynamic one in which the atoms are in motion, vibrating back and forth about equilibrium positions. This picture follows naturally from the theory that heat is a form of energy. A solid or liquid possesses energy because of the kinetic and potential energy of the individual atoms. Raising the temperature of a solid by adding heat to it increases its internal energy by increasing the amplitude of vibration of the atoms. The frequency of the atomic vibrations is determined by the forces which bind the atoms together.

### ELECTRICAL CONDUCTIVITY

**Measurement of Conductivity.** A most striking property of solids is that they are divided into two distinct classes with respect to their ability to conduct an electric current. In one class are the metals with very large conductivities, of the order of $10^5$/ohm-cm. In the second class are the ionic, valence, and molecular crystals with very small conductivities, of the order of $10^{-12}$/ohm-cm. There are a relatively few substances with intermediate conductivities known as semiconductors. A great deal of evidence indicates that these substances owe their ability to conduct either to impurities or to imperfections in structure.

**Nonconducting Crystals (Insulators).** Although the origin of the conductivity of metals is clear, it is much more difficult to understand why the other classes of crystals do not conduct. The fundamental difference between insulators and metals is that in insulators the number of "free" electrons that can be accelerated by an electric field is vanishingly small, whereas in metals this number is approximately the same as the number of valence electrons. In ionic, valence, and molecular crystals, the grouping of electronic energy levels into bands and the total number of electrons are such as to leave the bands either completely filled or completely empty of electrons. As a result, the electrons cannot gain energy from an electric field.

### THE LIQUID STATE

The theory of the liquid state is considerably more difficult than that of the solid state, fundamentally because in discussing liquids it is not possible to separate the investigation of the thermal motion of the atoms from the study of the static structure imposed by the interatomic forces. As a result the theory of liquids is still incomplete.

**Effect of Temperature.** As the temperature of a solid is increased, there occurs at the melting point a discontinuous change in its properties. The density decreases by several per cent, and the liquid is unable to sustain shearing forces. It is clear that the atoms are, on the average, farther apart, and that the interatomic forces are weaker than in the solid. Examination of the liquid by the technique of X-ray diffraction shows that not only has the interatomic spacing increased but that the regular arrangement of atoms on a lattice has disappeared. It is true that in the vicinity of any given atom there is a semblance of the order present in a solid, but all trace of order disappears if a region containing many atoms is observed. The distance between pairs of atoms is different from pair to pair, and changes rapidly with the time for a given pair. Because of the weakening of the interatomic forces the amplitude of vibration of the atoms is greater than in the solid. This condition, coupled with the fact that there are many vacancies present, gives the atoms much greater mobility than in a solid, and they change positions relatively rapidly. The higher the temperature of the liquid, the less does the structure resemble that of a crystal and the more does it appear like that of a gas in which all trace of molecular order has disappeared.

**Supercooling.** Certain liquids can be supercooled, that is, they can be cooled to a temperature below their melting point, where the thermal motion of the atoms is of no more importance than in crystals, and yet they preserve the irregular structure of a liquid phase. Such supercooled liquids are not in equilibrium; eventually the thermal motion of the atoms rearranges the structure and a crystal lattice is formed. Ordinary glass is the most common and important example of a supercooled liquid. F. S. and R. J. M.

**SOLINGEN** [zo'lɪŋən], an industrial city in central western Germany, about 17 mi. northeast of Köln (Cologne), in the state (*Land*) of North Rhine-Westphalia, formerly a part of the Prussian Rhine Province. It lies on the Wupper River, on a height overlooking a bend in the river. Its industries reputedly originated with artisans brought from Damascus by Adolph IV of Berg during the Crusades. It was chartered in 1374 and was a member of the Hanseatic League. Lying on the southern edge of the great Ruhr industrial area, Solingen, particularly its aircraft industries, was very heavily bombed in World War II. After the war it was included in the British zone of occupation. Famed since the Middle Ages for its cutlery and hardware, its factories produce surgical instruments, machine tools, knives, scissors, saws, files, razors, bicycles, and other metal wares. Pop. 1953, 157,900. C. C. H.

**SOLIPSISM** [sɒ'lɪpsɪzəm], the philosophical theory that knowledge is confined to the states of the knower's own self. If a thinker holds, as Hume did, that everything experienced through the senses, such as color and sound, hardness and shape, consists merely of sensations in the experiencing mind, and that ideas are nothing but copies of these sensations, the step is an easy one to the two conclusions that nothing beyond these mental states can be known with certainty, and that it is uncertain whether anything beyond them exists to be known. Hume regarded both conclusions as logically inevitable, though he admitted that in practice he neither did nor could take them seriously. Solipsism is the farthest point to which philosophic skepticism has been carried. *See also* IDEALISM; SKEPTICISM; SUBJECTIVISM. B. B.

**SOLITAIRE,** any one of a number of species of medium-sized New World thrushes combined in the genus *Myadestes.* They inhabit the mountains of western North America, Central and South America, and some of the West Indian islands. Their plumage is usually quiet patterns of grays, browns, and white; that of the only species found in the United States, *M. townsendi,* is mainly a brownish gray bird, about 8 in. long, with touches of white in the wings and tail. As a group they are famous for their songs, which are rendered in unusually strong, clear voices. The popular name, first given them by early French travelers, is derived from their shyness and their custom of living in wild regions at a distance from human habitation. H. G. De.

**SOLITAIRE.** *See* CARD GAMES.

**SOLMIZATION** [sɒ'lmɪze'shən], a musical system designating scale tones by the use of syllables instead of the usual letter names. The system most widely used today, based on the eleventh century Guidonian hexachord, consists of the following syllables: *do, re, mi, fa, sol, la, si,* or (*ti*). The two modern ways of applying them are called the "fixed *do*" and the "movable *do.*" The Continental "fixed *do*" invariably applies the above syllables to the tones of the C major scale, and the syllables of any other scale are reckoned from this norm. The "movable *do*" series, used almost exclusively in Great Britain and the United States, applies to any major scale so that each syllable takes on a particular tonal function, i. e., *do* is always the first tone, *sol* is always the fifth tone, and so forth. The "movable *do*" has wider and more practical usage, especially in teaching rudimentary musical subjects such as scales, various clefs and intervals. Use of the solmization principle is very old. Ancient Greek, Chinese, and Hindu systems are among those that antedate the eleventh century Guidonian method. In the last five hundred years several other systems have been introduced, but none has become permanently important. One modern substitute which uses numbers instead of syllables has been introduced with some success by the Eastman School of Music in Rochester, N. Y. *See also* GUIDO D' AREZZO. F. C. C.

**SOLO.** *See* SOERAKARTA, SURAKARTA, or SOLO.

**SOLO** (*It.* "alone"), a musical composition to be executed by one performer either with or without accompaniment. In orchestral and band music, passages marked "solo" are meant to be given special prominence as opposed to routine passages which must be carefully blended into the ensemble. In concertos, a distinction is made between solo passages, in which the orchestra is subordinate to the soloist, and tutti passages in which the orchestra alone is heard. W. Li.

**SOLOGUB, FYODOR** [sʌlʌgu'p], pseudonym of Fyodor Kuzmich Teternikov (1863-1927), Russian poet, novelist and dramatist. Sologub was born in St. Petersburg (Leningrad), the son of a tailor and of a house servant. After the early death of his father, he was brought up in a cultured family where his mother was employed. After graduating from a teachers' college in 1882, Sologub taught school for seven years in several provincial towns where his cheerless experi-

ences, before he was transferred to St. Petersburg, provided the substance for his later novels, *Heavy Dreams* (1896) and *The Little Demon* (1905). *The Little Demon,* written between 1892 and 1902, is his prose masterpiece and one of the principal works in the literature of Russian symbolism. He started publishing poetry in 1884, and collections of his poems appeared in 1896, 1904, 1906, and 1908. In 1908 he published a collection of translations from Paul Verlaine. Sologub's talent reached its highest expression in his somewhat difficult but interesting and highly suggestive poetry. In 1907, when he retired on a pension after twenty-five years of teaching, he was at the pinnacle of his fame. He died in St. Petersburg on Dec. 6, 1927.

Sologub had a most unusual attitude toward life and death, for he rejected the visible world created by God as something inexpressibly vulgar and looked for an ideal world of beauty in death ruled by Satan. Much of his poetry, perfect in form, is permeated with extreme eroticism. He also wrote numerous short stories, in which his tragic pictures of unhappy children are disturbingly effective. During the symbolist phase of the Moscow Art Theatre and of the Russian stage generally, he wrote a number of symbolist dramas, of which the most striking are *The Gift of the Wise Bees* (1906) and *The Triumph of Death* (1907), the latter based on the old French legend of Bertha of the Big Foot, mother of Charlemagne. Sologub's complete works appeared in 12 volumes in 1909-1912 and in 20 volumes in 1912-1914. L. I. St.

**SOLOLÁ** [sololɑ′], the capital of the department of the same name in Guatemala. The city is situated at an altitude of 7,100 ft. near Lake Atitlán, about 45 mi. northwest of Guatemala City. Most of the inhabitants of the city are Cakchikel Indians, who once had the city as their capital. Sololá's market is a trade center for the agricultural products of the surrounding region. Earthquakes are frequent, and in 1902 the town was almost totally destroyed by one, but it has since been rebuilt. The department of Sololá comprises an area of approximately 410 sq. mi. Pop. 1940, 16,233. S. G. I.

**SOLO MAN.** *See* Evolution of Man.

**SOLOMON,** in the Old Testament, the son of King David and the third and last king of a united Israel. He reigned for forty years (c. 977-c. 937 B.C.). The name Jedidiah, which means "beloved of God," was given to him at birth by the prophet Nathan (II Sam. xii:25); the name Solomon (Heb. *Shlomoh,* "peace") was his throne name and symbolizes the peaceful nature of his reign.

Solomon was one of the four sons of David and Bathsheba (I Chron. iii:5; xiv:4). Through the intervention of Bathsheba and Nathan, David appointed him his successor in preference to his son Adonijah. There is a Jewish and Arabic tradition that Solomon was only twelve years old when he began to reign; it is more probable that he was about twenty. In order to secure his throne, Solomon struck at those he considered his or his father's enemies. He had Joab, Shimei, and Adonijah put to death, and he replaced the high priest who favored Adonijah.

Solomon established himself as a strong and influential ruler. By building a number of fortifications, and entering into alliances with Tyre and Egypt, he strengthened his kingdom politically; by making commercial treaties with neighboring countries, sending out fleets to distant countries, and establishing smelting works in Ezion-Geber, he strengthened it commercially; and by dividing the country into districts, which were governed by his appointees, he unified its inner administration. He built a beautiful palace, developed an elaborate and extravagant court life, and maintained a large harem. He married the daughter of Pharaoh, receiving the city of Gezer as a dowry. His primary achievement was the building of the Temple in Jerusalem which centralized religious worship and became the historic symbol of Jewish religious glory and splendor. Solomon's activities, however,

CULVER SERVICE

*THE JUDGMENT OF SOLOMON*

FROM A PAINTING BY RAPHAEL

placed a great financial burden on the people, engendering a discontent which led to the disruption of the kingdom after his death.

Very early in his reign, Solomon gained a reputation as a wise man and ruler. His wisdom, which has become proverbial, is illustrated in the Bible by his judgment in the case of the two women who claimed the same child as their own (I Kings iii:16-28), and by the account of the visit of the Queen of Sheba, who "came to prove him with hard questions" (I Kings x:1-10). A large body of legends and traditions has developed around his personality. He is supposed to have mastered the language of animals and to have been able to communicate with and hold in his sway the demons and their chief, Asmodeus. The Book of Proverbs, the Song of Songs, and the Book of Ecclesiastes are traditionally attributed to him. M. A. G.

**SOLOMON ISLANDS,** a double row of large, mountainous, essentially volcanic islands with adjacent smaller islands and islets in the South Pacific Ocean east of New Guinea, 3° to 12° S. lat., 154° to 163° E. long., extending over a region 600 mi. long and 1,000 mi. wide. Total area is about 16,310 sq. mi. Peaks of the Crown Prince Range rise to more than 10,000 ft. (Mount Balbi), on Bougainville, the largest island of the group, 110 mi. long, 20 to 35 mi. wide; and over 8,000 ft. (Mount Lammas), on Guadalcanal,

the second largest. Other islands are Malaita, New Georgia, San Cristobal, Santa Isabel, Choiseul, Florida, Vella Lavella, Kolombangara, Buka, Shortland, Rendova, Vanguna, Rennell, and Tulagi. The group was discovered about 1567 by a Spaniard, Alvaro de Mendaña, but not until 1875 were traders living on the islands.

The climate is hot and damp, the flora luxuriant, and much of the animal life related to that in New Guinea. Most of the natives are Melanesians with a few Polynesians. In 1940 there were about 50,000 acres of coconut plantations in the group, and copra was the leading export. Other products are kauri wood, ivory nuts, trochus shell yielding mother-of-pearl, and smoked and dried trepang (*bèche-de-mer,* sea cucumber), prized as a delicacy by the Chinese. During World War II the group was the scene of large-scale naval, air, and land battles between Japanese and Allied forces, the great land battles being fought chiefly on Guadalcanal, the New Georgia group, and Bougainville.

**Political Divisions.** *British Solomon Islands Protectorate.* The British Solomon Islands Protectorate lies in the approximate area enclosed by 5° to 12° 30′ S. lat. and 155° 30′ to 169° 45′ E. long. Guadalcanal, Malaita, San Cristobal, and New Georgia came under British "protection" in 1893, followed in 1898 and 1899 by Santa Isabel, Choiseul, Shortland, Mono (or Treasury), Vella Lavella, Ronongo, Gizo, Rendova, Russell, Florida, Rennell, and smaller islands including the Lord Howe group or Ongtong Java, the Santa Cruz Islands, Ticopia and Mitre islands, and the Duff, or Wilson, group. Guadalcanal, the largest island, has an area of 2,500 sq. mi. Malaita, with 40,000 inhabitants, is the most populous. The total area of the protectorate is about 12,400 sq. mi., with a population, mostly native, of 94,105 in 1931. The resident commissioner's headquarters are on Guadalcanal. There is an advising commission but no representative body.

*Australian Mandate.* Since 1920, Bougainville, Buka, and adjacent islands, including Nissan, Kilinailau, Tauu (Mortlock), and Nukumanu (Tasman) islands, all formerly included in German New Guinea, have formed part of the Australian mandated territory of New Guinea. Bougainville, the largest island, has an area of 3,880 sq. mi. In 1931 its native population, including that of near-by Buka (190 sq. mi.) was 50,206. The other islands are about 30 sq. mi. in area, with a small population. R. G. B.

**SOLOMON'S-SEAL,** a genus, *Polygonatum,* of about 30 perennial herbs of the lily family. These plants are found in north temperate regions; two are common in the woods of eastern and central North America. They have thick horizontal rootstocks, marked with seal-like scars where the old stems have disappeared. The unbranched leafy stems are erect or arching, and bear small, greenish or pinkish flowers drooping from the axils of the sessile leaves on slender stalks. The small Solomon's-seal, *P. biflorum,* grows about 3 ft. high, and the great Solomon's-seal, *P. commutatum,* sometimes reaches a height of 8 ft. J. C. Wis.

**SOLOMON'S-SEAL, FALSE,** a small genus, *Smilacina,* of perennial woodland herbs of the lily family found in the Northern Hemisphere. *Smilacina racemosa* sends up in spring from a thickened rootstock a stem about 2 to 3 ft. high with alternate leaves, terminating in a panicle of tiny white flowers. A cluster of dull red translucent berries develops during the summer. It is common in North America, and both the starchy rootstock and the berries were used for food by the North American Indians. J. C. Wis.

**SOLON** [so′lɒn; so′lən] (c. 640-c. 559 B.C.), Athenian statesman, was born in Athens about 640 B.C. In order to avert civil war the Athenians in 594 B.C. elected Solon as archon and empowered him to institute political and economic reforms. Solon first freed those who had been enslaved for debt, and enacted a law which forbade loans in which the loss of personal freedom was the penalty for default. Other economic reforms encouraged olive culture in Attica and stimulated the growth of Athenian trade and industry. In the political field Solon set up a timocratic government at Athens by grading political eligibility and activity in terms of income. All citizens were arranged in classes according to their wealth. The *hippeis* or knights, the wealthiest class, were eligible to sit in the council and to hold the highest magistracies. The *zeugitae* or middle class could hold lesser offices and be members of the council, whereas the poorer citizens or *thetes* could participate only in the assembly. The council, better known as the Council of the Four Hundred, was another of Solon's innovations; its members were annually elected by the four Athenian tribes, one hundred persons from each tribe. The council advised and supervised the magistrates, and drafted legislation to be presented to the assembly for enactment. Solon also established a court of appeal, the Heliaëa. It was actually the assembly, with a quorum of six thousand, sitting as a court to hear appeals from sentences involving penalties of death, banishment, or heavy fines. Solon died about 559 B.C. T. B. J.

**SOLOTHURN** [zo′loturn], the name of a canton and its capital in northwestern Switzerland.

**The Canton.** With an area of 306 sq. mi., and an irregular shape, the canton consists of the Aare Valley, but an extension crosses the Jura Mountains to the north, and one isolated section reaches the French-Swiss frontier. The canton is enclosed by Bern on the south and west, Basel on the north,

SOLOMON'S-SEAL, POLYGONATUM BIFLORUM
FROM WILLIAM WOODVILLE'S *MEDICAL BOTANY*

and Aargau on the east. Most of the population is concentrated in the area of plain along the Aare Valley. North of the city of Solothurn rises the Weissenstein section of the Jura, with the highest point, Hasenmatt, 4,751 ft. The Aare River receives the Wigger at Aarburg and the Dunneran from Jura at Olten. The River Birs flows in the northern part of the canton. Pop. 1953, 178,600.

**The City.** The capital city is situated 19 mi. north-northeast of the city of Bern, on the Aare River at the foot of the Weissenstein Range of the Jura, between Biel and Olten. Industrial products are jewelry, shoes, cotton, motor parts, and cement. Pop. 1953, 17,500.

The city of Solothurn grew up around the house of secular canons founded in the tenth century by Queen Bertha, wife of King Rudolph II of Burgundy, in honor of Saint Ursus and Saint Victor. It became a free city of the Holy Roman Empire in 1218. During the fourteenth century the government of the town was assumed by the guilds. Solothurn was admitted to the Swiss Confederation along with Fribourg at the Diet of Stans in 1481. In 1529 most of the communes in Solothurn went over to the Reformed Church. S. Van V.

**SOLOVYOV, VLADIMIR SERGEYEVICH** [sʌlʌ-vyɔ′f] (1853-1900), Russian philosopher, mystic, poet, and publicist, was born in Moscow on Jan. 16, 1853. His father, Sergei Mikhailovich, son of an orthodox priest, was a great Russian historian. His mother, Poliksevna Vladimirova *née* Romanova, came from the same family as the Ukrainian philosopher Gregory Savich Skovroda (1722-1794). Solovyov was graduated from the Fifth Moscow Gymnasium with a gold medal, studied physics and mathematics for two years at Moscow University, and passed on to history and philosophy; during that period he took a course at the Moscow Theological Academy. In 1873 he was graduated from the University and in 1874 prepared the *Crises of Western Philosophy* as his Master's thesis. He received an appointment as Fellow of the University of Moscow and visited England, France, Italy, and Egypt. In 1880 he presented the *Criticism of Abstract Principles* as the dissertation for his Doctorate in Philosophy. He then resigned his position in Moscow University and went to St. Petersburg, starting to give public lectures and write his works. Solovyov was helpless and impractical; everything he had went to the poor; he had no permanent residence and died as a guest in the house of his close friend, Prince Troubetzkoy, near Moscow on July 31, 1900.

The aim of Solovyov's philosophy is to "justify the faith of the Fathers," to justify faith by reason. Theocracy under a universal church, he said, is the purpose of history. Eventually, however, he saw that the Kingdom of God could be fully actualized only after the apocalyptic transfiguration of humanity and of the universe, but he felt that the process of ascent from "Man-Beast" to "God-Man" must go on. The doctrine on "Sophia," "Man-Godhood," the deification of humanity, is the legacy of Solovyov to Russian theology, and it influenced the prose works of Sergius Boulgakov, Nikolai Berdyayev, and the poetry of Alexander Blok and Andrei Belii. Solovyov's most important technical contribution to philosophy is his concept of the "Absolute" as the subject of Being, in his work *Criticism of Abstract Principles*. His poems show an absorbing interest in "eternal Beauty," with an almost religious expectation of its realization. Solovyov's most important works are: *Crisis of Western Philosophy* (1874), *Philosophical Foundations of Integral Knowledge* (1877), *Lectures on God-Manhood* (1878), *Criticism of Abstract Principles* (1880), *Spiritual Foundation of Life* (1882), *The History and the Future of Theocracy* (1886), *Justification of Good and the Three Dialogues—Including Narration on Anti-Christ* (1896-1900). P. P. Z.

**SOLSTICES** [sɒ′lstɪsəz], points on the ecliptic, midway between the two equinoxes. The summer solstice for the northern hemisphere is the point at celestial longitude 90° (right ascension $6^h$) where the sun enters the sign of Cancer and attains its greatest northern declination (+23½°). At this point it is the beginning of summer in the northern hemisphere. The same point and time become the winter solstice for the southern hemisphere. The point is at the border of the constellations Gemini and Taurus and is reached on the average on June 21. The winter solstice for the northern hemisphere is the point at longitude 270° (right ascension $18^h$) where the sun enters the sign of Capricorn and attains its greatest southern declination (−23½°). At this moment it is the beginning of winter in the northern hemisphere. The same point and time become the summer solstice for the southern hemisphere. The point is in the western part of the constellation Sagittarius and is reached on the average on December 22. The term solstice is thus applied chiefly to the locations on the celestial sphere but also to the moments of time. H. S. R.

**SOLUTION, CHEMICAL,** a homogeneous mixture of two or more substances, there being only one phase, which may be either gaseous, liquid, or solid. The molecules of each component of the solution are completely and uniformly dispersed among those of the others. The component present in largest amount in a solution is called the solvent, whereas the one (or ones) present in smaller proportion is referred to as the solute (or solutes). When a given quantity of solvent has dissolved as much of a particular solute as it possibly can at a specified temperature and pressure, the solution is said to be saturated.

## SOLUBILITY

The concentration of a solution, expressed in suitable terms, is referred to as the solubility of the solute in the given solvent under the specified conditions. The solubility of one substance in another is usually affected by the temperature and, particularly when a gas dissolves in a liquid, by the pressure. The process of solution is almost invariably accompanied by a heat change, referred to as the heat of solution; this may be positive or negative for different solvents and solutes, and may vary to some extent with the concentration of the solution.

**Gases.** Provided there is no chemical interaction, gases can be mixed with one another in all proportions. Consequently, for a solution of one gas in another there is no solubility limit and the question of saturation does not arise. However, when a gas is dissolved in a liquid there is a definite maximum solubility, i.e., a saturated solution, at any given temperature and pressure. The solubilities of a series of gases in a particular liquid are, in general, related to their ease of liquefaction. The more readily liquefiable gases, e.g., ammonia, sulphur dioxide, and hydrogen chloride, are usually more soluble than those, e.g., oxygen, hydrogen, and helium, which are difficult to liquefy (*see* Table 1). Chemical interaction between the gas and the solvent, such as probably occurs when ammonia and hydrogen chloride are dissolved in water, results in an increased solubility. Although the solubility of a particular gas varies with the nature of the solvent, the order of increasing solubility of a number of gases is approximately the same in different solvents.

The solubility of a gas in a liquid is best expressed in terms

Table 1. Solubilities of Certain Gases
*(Volume in liters absorbed in 1 liter of water)*

| *Name of Gas* | *At 0° C. and 760 mm.* | *At 20° C. and 760 mm.* |
|---|---|---|
| Ammonia | 1,300 | 710 |
| Carbon dioxide | 1.71 | 0.878 |
| Chlorine | .... | 2.26 |
| Hydrogen | 0.0215 | 0.0184 |
| Hydrogen chloride | 506 | 442 |
| Nitrogen | 0.0235 | 0.0164 |
| Oxygen | 0.049 | 0.031 |
| Sulphur dioxide | 79.789 | 39.374 |

of the mole fraction (*see* Concentration, *below*), but since the values are often very small they are not convenient. An alternative method makes use of the absorption coefficient discovered by R. Bunsen in 1857, which is the volume of gas, reduced to 0° C. and 1 atmosphere pressure, dissolved at saturation by unit volume of solvent at the temperature of the experiment and under a pressure of one atm. of the gas. Since a gram-molecular weight of any gas occupies approximately 22.4 liters at 0° C. and 1 atm., it follows that if the absorption coefficient is divided by 22.4, the result is the solubility of the gas, at the experimental temperature and 1 atm., expressed in moles per liter of solvent or, approximately, of the solution.

When a gas dissolves in a liquid there is usually a liberation of heat; hence, from the Le Châtelier principle, increase of temperature should result in a decrease of solubility. This is generally the case, the effect being more marked for the very soluble gases. The "flat" taste of boiled or distilled water is attributed to the fact that the dissolved air is expelled upon boiling, its solubility being very small at the higher temperature.

Increase of pressure results in an increased solubility of a gas. According to Henry's law, which is obeyed well by the sparingly soluble gases but only approximately by the very soluble ones, the weight of gas that can be dissolved by a given volume of liquid, at constant temperature, is proportional to the pressure of the gas. This behavior is utilized in the preparation of artificially carbonated beverages. Carbon dioxide gas is dissolved in the liquid at a pressure of 3 to 4 atm., so that the weight of gas dissolved is three to four times that at 1 atm. pressure. When the bottle is opened, the pressure is decreased, and some of the dissolved gas is liberated in the form of bubbles, thus producing the familiar "sparkling" effect. Natural carbonated waters, e.g., Seltzer and Apollinaris waters, are formed in a similar manner by underground water dissolving carbon dioxide under pressure.

When gases dissolve from a mixture, instead of from the pure gas, each gas behaves independently of the others, and the amount that dissolves is the same as would have been the case for the pure gas at the same pressure it has in the mixture. This pressure is not the total gas pressure of the mixture, but the pressure which the particular gas contributes to the total, often referred to as the partial pressure of the gas in the mixture.

**Liquids.** Many pairs of liquids are able to mix with one another in all proportions, a homogeneous solution being formed irrespective of the relative quantities of the two liquids present. This result occurs when the liquids are similar or are related chemically, e.g., water and ethyl alcohol, and benzene and toluene, or if the molecules have a strong attraction for one another, possibly combining chemically. At the other extreme are found pairs of liquids which are so dissimilar that they are essentially immiscible, and neither liquid will dissolve the other, e.g., mercury and water, benzene and water. Between the two extremes lies an important type of system consisting of pairs of liquids that are partially miscible, e.g., water and ether. If two such liquids, A and B, are mixed, two layers will generally be formed, one being a saturated solution of A in excess of B, and the other a saturated solution of B in excess of A. The compositions of these two layers at equilibrium, called conjugate solutions, are perfectly definite, depending only on the temperature and to a very minor extent on the pressure. These compositions, are, however, independent of the relative amounts of the liquids A and B, provided only that the proportions are within the range for the existence of two conjugate layers. As a rule the mutual solubilities of two partially miscible liquids increase as the temperature is raised, and eventually a point is reached at which the liquids become miscible in all proportions. This point is known as the critical solution (or consolute temperature) of the system.

In a few instances, the mutual solubilities of two partially miscible liquids increase as the temperature is lowered. This effect occurs when heat is evolved upon mixing the liquids, usually as a result of chemical interaction. If the temperature can be decreased sufficiently without the system freezing, a lower critical solution temperature, in contrast to the upper temperature described above, may be observed. It is probable that all systems exhibiting a lower critical-solution temperature would also show such an upper temperature, although the reverse is not necessarily true. In most cases, however, one or other of the liquids boils before the upper critical solution temperature is attained. The nicotine-water system has a lower critical solution temperature at 61° C. and an upper temperature at 208° C. Below the former temperature and above the latter these liquids are miscible in all proportions, but within this temperature range they are only partially miscible.

**Solids.** Solids invariably exhibit a limited solubility in liquids. The composition of the saturated solution has a definite value at each temperature, depending on the nature of the solute (solid) and solvent (liquid) (*see* Table 2). The

Table 2. Solubilities of Certain Solids
*(Grams in 100 grams of water)*

| *Substance* | *0° C.* | *20° C.* | *100° C.* |
|---|---|---|---|
| Barium chloride, $BaCl_2 \cdot 2H_2O$ | 31.6 | 35.7 | 58.8 |
| Boric acid, $H_3BO_3$ | 1.95 | 4.00 | 27.5 |
| Calcium hydroxide, $Ca(OH)_2$ | 0.185 | 0.165 | 0.077 |

solubility of sodium chloride in water is several million times as great as that of naphthalene; on the other hand, the situation is reversed when benzene is the solvent. The behavior is an illustration of the general rule that a solid will dissolve readily in a liquid to which it is related in certain chemical and physical properties, but will usually not dissolve in a liquid having an entirely different character.

Salts, in general, dissolve in water (*see* Table 3) and, to some extent, in related solvents such as alcohol and liquid ammonia. Even among salts, however, there are considerable

TABLE 3. SOLUBILITIES OF SOME SALTS AT 20° C.*

Expressed as the number of grams of the anhydrous salt held in solution by 100 cc. of water. In a few cases the temperature is other than 20° C.; in these instances the temperature is noted as a superscript. Notation: $0.0_82$ means 0.0000002.

* Reprinted from Foster and Alyea, *An Introduction to General Chemistry,* third ed., 1947, by permission of the publishers, D. Van Nostrand Company, Inc., New York.

variations; thus, ammonium nitrate is many million times more soluble in water than is silver iodide.

When a solid dissolves in a liquid, heat is usually absorbed; i.e., the heat of solution is negative. Hence, by the Le Châtelier principle, the solubility of the solid should increase with rising temperature. Such is the case, although the extent of the increase varies considerably from one solid to another. In a few instances, e.g., calcium sulphate and acetate in water, the solubility decreases to some extent as the temperature is raised. When the solubility increases appreciably with the temperature, the process of purification by recrystallization is possible. The impure solid is dissolved at a high temperature and the saturated solution is cooled. The excess solid solute then separates out, and the impurities largely remain in solution.

Solids can be completely or partially miscible, or completely immiscible with one another, just like liquids. Two suitable solids can thus form a homogeneous mixture that is a true solid solution, analogous to a liquid solution. Partially miscible solids can, similarly, form two conjugate solid solutions in equilibrium; the compositions of these solid solutions vary with the temperature, and critical solution temperatures are possible. Many pairs of metals are completely miscible in the solid state, whereas others are partially miscible or are virtually immiscible. These facts are of great importance in connection with the study and production of metallic alloys.

Solid solutions are not prepared by mixing the solids, because of the slowness with which the atoms or molecules of one solid would diffuse among those of the other. For metals and certain solids that can be melted without decomposition, the two solids are mixed and heated until they are completely molten; upon cooling the resulting liquid, the solid solution separates out. A mixture of suitable isomorphous salts may be dissolved in water, and upon evaporating or cooling, a solid solution of the two salts will crystallize from the liquid solution.

**Distribution Between Solvents.** If any solute is added to a system of two immiscible or slightly miscible liquids, the solute distributes itself between the two liquid solvents in a definite manner. Provided the solute has the same molecular weight in the two solvents, the ratio of its concentrations in the two layers is found to be constant, at any given temperature, irrespective of its total amount. This rule is known as the distribution law, or partition law; and the ratio of the concentrations is called the distribution ratio, or partition ratio, of the solute for the two specific liquids. The distribution ratio is approximately equal to the ratio of the saturation solubilities, so that a solute distributes itself between two liquids roughly in proportion to its normal solubility in those liquids. This result is utilized in the laboratory and in industry for the extraction of a required substance from its solution in one solvent by the use of another solvent. Another application is in the Parkes process for extracting silver from lead, with which it is frequently associated in nature. The impure lead is melted and molten zinc is added, thus forming two almost immiscible liquid solvents. The silver, which is present in the lead, distributes itself between the two liquid layers, the larger proportion passing into the zinc layer, in which it is more soluble. The upper (zinc) layer is then separated, and the zinc is removed by distillation, leaving most of the silver originally present in the lead.

## CONCENTRATION

**Molality.** The concentration of a solution is a means of expressing its composition in a convenient form. The concentration may be stated in terms of the percentage composition, but for most scientific purposes other methods are used. For example, the molar concentration, or molarity, of a solution is the number of moles, or gram-molecular weights, of the solute present in 1 liter of solution. Since the volume of a solution varies with the temperature and pressure, the molarity of a given solution will change accordingly. This

variability is a disadvantage for certain theoretical studies, and therefore the molality, which is independent of temperature and pressure, is used. The molality of a solution is the number of moles of solute to 1,000 grams of solvent. For a given solvent and solute, the molarity and molality of a series of solutions of different concentrations are proportional to one another, provided the solutions are dilute. For moderately concentrated solutions the proportionality no longer holds.

**Mole Fractions.** In many circumstances it is neither possible nor desirable to distinguish between solvent and solute; the mole fraction may then be employed to express the composition of a system. The mole fraction of any constituent of a solution, which may be gaseous, liquid, or solid, is the number of moles of that constituent divided by the total number of moles of all the substance present. The mole fractions of all the constituents of the solution thus add up to unity. An exact relationship may be derived between the mole fraction of a solute and its molarity and molality; for dilute solutions of a given solute and solvent, these three quantities are proportional to each other.

**Normality.** A convenient method for expressing concentrations, which is widely used in quantitative chemical analysis, is to state the normality of a solution. A normal solution of given solute contains 1 gram equivalent weight of that solute for liter of solution. A given volume of a normal solution of one solute, e.g., an acid or an oxidizing agent, is chemically equivalent to the same volume of a normal solution of another solute, e.g., a base or a reducing agent, respectively. The normality of any solution is the concentration in terms of that of the normal solution taken as unity.

A less precise indication of concentration makes use of the saturated solution as the reference standard. A solution containing less than the saturation amount of solute, at the given temperature, is said to be unsaturated; but if by some device it is made to contain more, it is called a supersaturated solution. An even more indefinite description is to refer to solutions as dilute or concentrated, with various qualifications. *See also* CHEMICAL EQUILIBRIUM; EQUIVALENT WEIGHT; METALLURGY, PHYSICAL. S. Gl.

**SOLUTREAN** [solu′triən], the name applied by archaeologists to an Upper Paleolithic culture from Solutré, near Mâcon, Saône-et-Loire, France, where the first examples of this culture were found. Highly typical are leaf-shaped lanceheads with shallow pressure-flaking on either face. Traces of this culture have been found in France, northern and eastern Spain, and in parts of central Europe. J. G. D. C.

**SOLVAY, ERNEST** [sɔ′lve′] (1838-1922), Belgian inventor of the ammonia process for making sodium carbonate (washing soda), was born on April 16, 1838, at Radeck. Educated at Liége, he showed great interest in industrial chemistry, and in 1863 opened a factory at Couillet, Belgium, for the manufacture of soda by his process. By 1913 he had obtained a virtual monopoly of the world's supply of soda. There is a large soda-ash works located in Solvay, New York. Service to his native country included membership in the Senate (1893-1900), philanthropy to both educational and charitable purposes, and supervision of the distribution of foodstuffs from the United States to France and Belgium during World War I. Solvay founded the École de Commerce and École de Sciences Politiques et Sociales, also the International Institute of Chemistry and Sociology, all in Belgium. He was president of the International Institute of Bibliography, Grand Officer of the Order of Leopold, honorary member of the Royal Institute of Great Britain, and Lavoisier medalist of the Institute of France. He died in Brussels, May 26, 1922. H. N. A.

**SOLVAY** [so′lve], a residential and industrial village in central New York, in Onondaga Co., situated near Lake Onondaga, 3 mi. west of Syracuse. Founded in 1884, it was incorporated as a village in 1894. Solvay has the mayor-council form of government. Transportation is supplied by the New York Central and the Delaware, Lackawanna and Western railroads. Solvay is widely known for its manufacture of soda and soda ash. Besides these products, the factory output includes dyes, ammonia, and oven coke. Pop. 1950, 7,868.

**SOLVENTS, INDUSTRIAL,** are used commercially for preparing solutions (molecular dispersions) of one material, known as the solute, in another, called the solvent. Solutions differ from mechanical mixtures in that they are homogenous throughout. Unlike true chemical compounds, the proportions of the components of a solution are not fixed but may vary up to the limit of solubility of one material in the other.

**Liquid Solvents.** Although solids, liquids, or gases may form solutions, the most common types are those in which a liquid is the solvent. When a solution is composed of two liquids, either may be considered as the solvent; however, this term usually designates the one present in the larger proportion. Most industrial solutions contain more than two ingredients, and frequently more than one solvent. Water meets many of the requirements of an ideal solvent. It is cheap, nontoxic, noninflammable, has a high solvent power for many materials, and is stable to heat. Also its boiling point is high enough to permit handling at room temperature without excessive solvent losses, and yet low enough to evaporate in a reasonable period of time. Its principal disadvantages are that it requires more heat to vaporize than other liquids; it is difficult to remove from many materials; and often fortunately, it will not dissolve everything. For these and other reasons, a wide variety of solvents have come into use. They may be divided into reactive solvents, which change the solute chemically in such a way that the original material cannot be recovered by evaporating the solution, and nonreactive solvents, which do not affect the chemical nature of the solute. Most industrial solvents are of the nonreactive type.

*Composition.* Solvents vary in chemical composition. The simplest are the hydrocarbons derived from coal tar or petroleum. These materials are cheap and consequently are used whenever possible. The main disadvantages of the hydrocarbons are their flammability and relatively low solvent power for certain materials. The chlorinated hydrocarbons are better solvents and much less flammable. Certain members of the series are toxic, however, and their use is restricted to applications which can be carried out without endangering the operators. In general, the oxygen-containing solvents, including alcohols, ketones, ethers, and esters, are more expensive than the hydrocarbons or chlorinated hydrocarbons, but in many applications none of the less expensive types perform satisfactorily.

*Uses in Protective Coatings.* One of the largest users of solvents is the protective coating industry, which manufactures paints, varnishes, lacquers, and various other specialized coatings. Paints and varnishes form a protective film by the drying of the oil base after the solvent has evaporated, and the primary purpose of the solvent is to thin the drying oil

to the correct viscosity for brushing. Gum turpentine was preferred for this purpose for many years, but recently substitutes derived from coal tar and petroleum have come into use. Unlike paints and varnishes, lacquers lay down a film by the evaporation of the solvent. The true solvents for nitrocellulose and other film-forming materials used in lacquers are relatively expensive; therefore diluents are added to reduce the cost of the solution. The choice of solvents and diluents must be made carefully if a satisfactory product is to be obtained. For example, it is necessary to balance the lower-boiling solvents, such as ethyl and isopropyl acetates and ethyl alcohol, with the higher-boiling butyl and amyl acetates and alcohols to prevent blushing or clouding of the film. Blushing occurs when moisture is condensed on the fresh lacquer film because of the cooling resulting from the rapid evaporation of low-boiling solvents. Unless higher-boiling solvents are present to carry off the water, a discolored and relatively nonadherent film is left. The lacquer formulator must also be sure that enough slower evaporating solvents are present to permit the film to flow to a smooth, even surface before it sets; otherwise buffing will be required to produce a satisfactory coating. The hydrocarbon diluents must evaporate before the last of the solvents, or an uneven precipitated film will result. These and many other problems must be solved in the formulation of a satisfactory lacquer.

Modified lacquers are used in coating textiles and leather. Since the coating and drying operations can be carried out under controlled conditions of temperature and humidity, it is possible to use a higher proportion of low-boiling solvents such as ethyl and isopropyl acetates, and even acetone, in the solvent mixtures. Low-boiling solvents are also used in coating textiles with some of the newer resins, such as the vinyls and cellulose acetate. Acetone is the principal solvent used in the manufacture of cellulose acetate rayon. Some of the coating compositions used for waterproofing textiles are similar to rubber cements, which consist of rubber dissolved in hydrocarbons. Chlorinated hydrocarbons may also be used, and these solvents are also valuable in cements based on oil-resistant synthetic rubbers.

*Other Uses.* Large volumes of solvents are used in various cleaning operations. Dry cleaning requires a solvent which will remove dirt and stains without affecting the dyes or the fabric. Stoddard solvent, a petroleum product boiling considerably higher than gasoline, is used in many operations, but because of its flammability it has been replaced to some extent by chlorinated hydrocarbons, such as trichloroethylene and carbon tetrachloride. Trichloroethylene and perchloroethylene are also used in degreasing metal and leather. The primary requirement for solvents to be used in the food, drug, and cosmetic industries is that they be nonpoisonous. In addition the solvent must not impart an undesirable taste or odor to the product. For these reasons ethyl alcohol is the preferred solvent for the preparation of tinctures, extracts, and other solutions. Polyhydric alcohols such as glycerin, and ethylene and propylene glycols, are also used where a less volatile material is required.

**Solvent Extraction.** Extracts are prepared by treating a solid or liquid with a solvent which will dissolve the desired components selectively. In this process, known as solvent extraction, the solvents must meet several requirements. They must dissolve the maximum amount of the desired component with a minimum of undesirable materials. The solution must be easy to separate from the undissolved substance. In the extraction of solids, this separation is usually not difficult, but in "liquid-liquid" extraction a solvent must be chosen which will separate quickly and completely from the liquid being extracted. The final requirement is that the solvent be easy to separate from the extracted material, usually by distillation, without affecting the quality of the product. Solvent extraction is widely used industrially. Almost every type of solvent finds some applications in this field. Petroleum derivatives boiling in the same temperature range as gasoline are used for the extraction of oil from soybeans and of chlorophyll from alfalfa. Alkaloids for pharmaceuticals are extracted with ether, and hormones are extracted with butanol. Methanol extracts the fatty acids, which become rancid, from the more stable acids; it also removes the sulphur-containing compounds which cause corrosion and undesirable odors in gasoline. Trichloroethylene and other chlorinated solvents are employed in the purification of vegetable oils, and butyl and amyl acetates extract penicillin from its fermentation liquor.

**Liquefied Gases.** In addition to solvents which are liquids under ordinary conditions, some liquefied gases are also used in solvent extraction. Propane, one of the components of natural gas, can be liquefied under pressure; and under the proper conditions liquid propane will extract vitamins from fish-liver oils. Asphalt is removed from lubricating-oil stock with the same solvent. Sulphur dioxide and ammonia are two other normally gaseous materials which have been proposed as suitable solvents for extraction. Solvent extraction is widely used in refining petroleum and vegetable oils, and new applications of this useful process are constantly being made. R. F. T.

**SOLWAY FIRTH** [sɒ′lwe], an arm of the Irish Sea extending nearly forty miles inland between England and Scotland. It is noted for its dangerous tides, which rise with rapidity to form a bore three to four feet high. It extends inland in a northwesterly direction and is bounded by the counties of Cumberland, Kirkcudbright, and Dumfries. The rivers Esk, Nith, Annan, Eden, Derwent, and others empty into it. The firth abounds with fish. S. Van V.

**SOMALI.** *See* African Peoples.

**SOMALILAND** [somɑ′lila′nd], a coastal region of east Africa extending from Bab el Mandeb Strait at the head of the Gulf of Aden east to the horn of Africa at Cape Guardafui and thence south and southwest to Ras Chiamboni (Dicks Head) southwest of the Giuba (Juba) River. To the west are Ethiopia and Kenya. The name is derived from the Somalis, a nomadic Moslem people of Hamitic stock and speech. Politically the region is divided into British, French, and Italian dependencies.

### BRITISH SOMALILAND

British Somaliland is a protectorate facing north on the Gulf of Aden. With a coastline of about 450 mi., it is bounded on the east and southeast by Italian Somaliland, on the south and west by Ethiopia, and for a short distance on the west by French Somaliland. The area is about 68,000 sq. mi.

**Geographical Features.** The main topographical features of the country parallel the coastline. The low, flat coastal plain extends inland about 60 mi. in the west and tapers to one or two miles in the east. Beyond the plain the land rises in precipitous escarpments to a lofty plateau, which slopes from an altitude of 7,000 ft. in the west to 2,000 ft. in the east. The climate is hot and arid, especially along the coast; rainfall averages from 8 to 20 in. a year. There is, however, considerable seasonal variation from this

average, which accounts to some extent for the migratory character of the population. Where rainfall is adequate there are a few small forest areas, but the country as a whole varies from desert scrub through grassland to park land. Varieties of gazelles are found on the plateau, and there the lion still preys on nomadic flocks.

**Population.** The population has been estimated to be between 500,000 and 700,000. Most of the people are nomadic Somalis who are Sunnite Moslems. Their principal occupation is grazing camels, sheep, and goats. The two towns of appreciable size are Berbera and Hargeisa, each with a population of about 15,000 in the hot season and 20,000 in the cooler season; Hargeisa is the capital. Non-natives include about 1,500 Arabs, about 500 Indians, and a very small number of Europeans.

*A ROPE MARKET AT HARGEISA, COMMERCIAL TOWN IN BRITISH SOMALILAND, IN WHICH WARES ARE DISPLAYED IN THE MIDDLE OF THE STREET*

COURTESY OF THE BRITISH INFORMATION SERVICES

**Economic Activities.** Little agriculture is practiced, and that is confined to the western part of the country. The principal export items are sheepskins and goatskins; some trade is done also in live sheep and goats, and such forest products as gums and resins. Frankincense and myrrh, once the chief source of wealth, have dwindled to insignificance. The export trade varies from about $1,000,000 to $2,000,000 annually. The country has no railways, but Berbera, an administrative center, is connected by air with Aden, to the north, and Nairobi, to the south. A reasonably good system of roads connects inland towns with those on the coast. Transport is by camel or motor car. The principal ports are Zeila, near the western border, and Berbera, 125 mi. east of Zeila. The East African shilling is used for currency.

**History and Government.** After the British established a protectorate over Aden in 1839, the Turks countered with a protectorate over Somaliland, but it was never effectively exercised. Between 1864 and 1884 Egypt established some control over Somaliland, but in the latter year this was replaced by a British force from Aden. Treaties were concluded with local chieftains, and in 1887 a formal protectorate was declared over the entire coast now within the limits of British Somaliland. Tribal warfare being endemic in the country, the British had frequent occasion to defend friendly clans against others, and in 1901 they were faced with a combined attack on their own forces by a group of clans under the leadership of Mohammed ibn-Abdullah, whom they called the Mad Mullah. Mohammed continued his attacks intermittently until 1920, when he was decisively beaten by a combined air and land attack.

Between 1884 and 1898 Somaliland was a dependency of Aden, which in turn was a dependency of India. From 1898 to 1905 it was under the direct control of the British Foreign Office and then was transferred to the Colonial Office. In World War II, from August 1940 to March 1941, the country was occupied by an Italian force; thereafter it was under a British military governor until April 1948, when civil government was resumed.

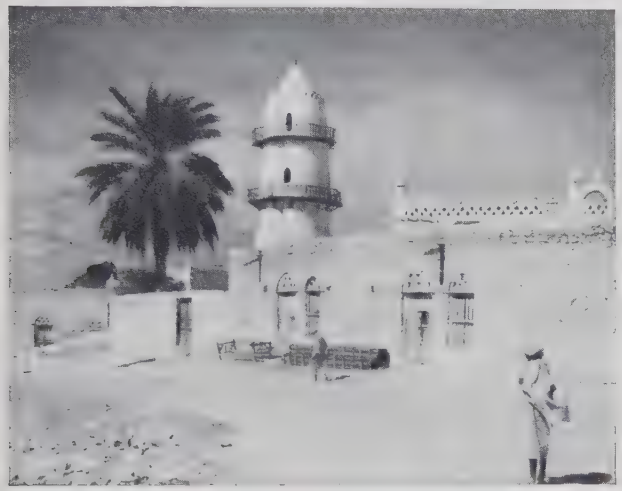
## FRENCH SOMALILAND

French Somaliland, a territory within the French Union, commands the narrow Bab el Mandeb Strait which connects the Red Sea and the Gulf of Aden. It is bounded on the north by Eritrea, on the west and south by Ethiopia, and on the east by British Somaliland, and the Gulf of Tadjoura. Across the strait is the tiny (1 sq. mi.) French territory of Cheik-Saïd, between Yemen and Aden. Smallest of the three dependencies, French Somaliland has an area of 9,071 sq. mi.

**Geographical Features.** The territory's coastline is so deeply indented (130 mi.) by the Gulf of Tadjoura that no part of the interior is more than 70 mi. from the shore. Such soil as is suitable for agriculture follows a low and narrow strip along the coast, but rainfall seldom exceeds 5 in. annually. Although there is greater precipitation farther inland where elevations are higher, the terrain is too rugged and the soil too thin for agricultural occupations.

**Population.** The population in 1952 was 61,625, including 27,360 Somalis, 25,202 Danakils, 6,007 Arabs, and 2,357 Europeans. The native groups are Moslems, largely Sunnites; however, the Danakils have retained many features of animistic fetish worship along with the practice of Islam. These people, most of whom live north of the Gulf of Tadjoura, regard themselves as Arabs, but speak a language akin to Somali. They are of Hamitic origin. Djibouti (pop. 1952, 27,723) is the capital.

**Economic Activities.** Except near the British Somaliland border, little of the territory is well suited to agricultural or even pastoral pursuits. The only major export is salt, but hides and coffee add some value to the export trade. The territory's major role is in its strategic commercial and military location. The railway to Addis Ababa (496 mi.) carries part of Ethiopia's trade with the outside world, despite the fact that the country's federation with Eritrea in 1952 gave landlocked Ethiopia an outlet to the sea. The monetary unit of French Somaliland is the Djibouti franc, which is valued at 214 to the U.S. dollar.



EWING GALLOWAY

*The ancient Mosque of Djibouti, capital city of French Somaliland, at which the Moslem inhabitants gather to worship*

**History and Government.** The French established a settlement at Obock on the Gulf of Tadjoura directly north of Djibouti in 1862 but did not take formal possession until 1883. Between 1883 and 1887 French boundaries were extended by treaties with local sultans, and in 1888 France secured from Great Britain undisputed control over the south coast of the gulf. The capital was moved from Obock to Djibouti in 1892. The Eritrean boundary, fixed in 1894, was readjusted in 1935 when France ceded 309 sq. mi. to Eritrea. France concluded a territorial and economic agreement with Ethiopia in 1897, and in the same year the construction of the railway was begun, although it did not reach Addis Ababa until 1917. Relations between French Somaliland and its neighbors have been amicable, thus maintaining for France a secure trading and fueling station on its route to Asia.

An appointed governor is responsible for administration. Since 1945 he has been assisted by an administrative council consisting of appointed and elected members with separate electorates for French citizens and native races. In each of the French governmental divisions—the French National Assembly, the Council of the Republic, and the French Union—the territory is represented by one delegate.

## ITALIAN SOMALILAND

Italian Somaliland, or just Somaliland, is a former Italian colony restored temporarily to Italian administration by the United Nations in December 1949. It has a coastline of 1,250 mi. facing east and southeast on the Indian Ocean; the coast continues around Cape Guardafui, giving it a 150-mi. shoreline facing north across the Gulf of Aden. It is bounded on the northwest by British Somaliland and Ethiopia, and on the west and southwest by Kenya. Largest of the dependencies, it has an area of about 190,000 sq. mi.

**Geographical Features.** Almost half of Italian Somaliland is less than 600 ft. above sea level, and only along the British Somaliland border do elevations reach more than 3,000 ft. The coastal lowlands, which are more than 200 mi. broad in the south, steadily narrow toward the northeast and disappear near Alula west of Cape Guardafui, where an escarpment of almost 1,000 ft. directly fronts on the sea. These higher areas of the northeast, however, receive less rainfall than the lowlands toward the southwest. In the lower Giuba and Shibeli valleys on the equator the precipitation may reach 30 in. annually, most of it between April and June; throughout most of Italian Somaliland, however, it is under 10 in. By far the greater part of the country must be classed as desert or semidesert. The only perennial rivers are the Giuba and its tributary, the Shibeli, both of which rise in the well-watered mountains of southern Ethiopia. The Giuba flows directly south from the Ethiopian border and empties into the Indian Ocean; the Shibeli farther to the northeast approaches to within 20 mi. of the sea in the vicinity of Mogadiscio, the capital, and then parallels the coast for over 200 mi. before emptying into the Giuba just before its mouth. The coastal region from Chisimaio near the mouth of the Giuba to Mogadiscio is known as Benadir. As a whole, the coast is poorly supplied with natural harbors; Chisimaio is the best, but breakwater construction at Mogadiscio offers protection against monsoons, and the port has adequate shipping facilities.

**Population.** The population in 1952 was about 1,280,000, the majority of whom were Somalis, a semi-nomadic pastoral people. There are also about 30,000 Arabs, 1,000 Indians, and 5,000 Italians. Some Bantus are found in the south, and there are communities of Arabs and Swahilis in the coastal towns. Most of the population is Moslem.

**Economic Activities.** The chief native crops are cereals such as maize, millet (sorghum), and vegetables, none of which is raised in excess of local needs. The principal exports are dressed sheepskins and goatskins, but there is also some export of cattle, myrrh, and gum arabic. Camels, an essential part of the native economy, are not raised for export. Between World War I and World War II Italian planters and plantation companies established irrigation farming on the lower Giuba and along the Shibeli. Some land, especially on the lower Giuba which has a flood plain about 4 mi. wide, is self-irrigating. Plantation crops include cotton, sugar cane, tobacco, and maize. There are no minerals, almost no secondary industries, and little trade. On balance Italian Somaliland has been an economic liability to the administering power.

**History and Government.** Within historic times Italian Somaliland has been successively under Portugal, Oman, Zanzibar, and Italy. In 1889 the Benadir coast was granted to Italy by the sultan of Zanzibar, and between 1893 and 1905 was leased to a private company. In the latter year the Italian government assumed control. Full sovereignty over the northeast was not established until 1925, although previously a group of protectorates had been set up over local sultanates. Here the situation had remained fluid, so long as Mohammed ibn-Abdullah, the Mad Mullah, continued to use this rugged region as a refuge from British attack farther to the west. With his final defeat in 1920 northeastern Italian Somaliland became fairly tranquil. In 1925 the British ceded the region to the west of the Giuba River known as Jubaland. The continued absence of any definite boundary between Italian Somaliland and Ethiopia, together with the seasonal migration of tribesmen between the two countries, has made for unsettled conditions in that region. With the Italian conquest of Ethiopia in 1936, all Italy's holdings in

east Africa were united under the name of Italian East Africa. Italian Somaliland was occupied by the British in 1941 and remained under British military administration until the United Nations, charged with the disposition of the former Italian colonies, decided to return the territory to Rome under a U.N. trusteeship in 1949. The U.N. decision, however, stipulated that the country was to become independent in 1960. Under the trusteeship arrangement, Italy's administration is reviewed annually at U.N. sessions, with member nations taking an active interest in Somaliland's progress toward self-government. The postwar period saw an emerging Somali political movement, and the territory's first municipal elections in 1954 resulted in widespread victories for the Somali Youth League, the leading nationalist party. W. M. W.

**SOMBOR** [so′mbor], an agricultural and trading town in Voivodina, Yugoslavia, about 95 mi. northwest of Belgrade and 20 mi. from the Hungarian border. It is on the Kanal Kralfa Petru (Francis Canal) which connects the Danube and Tisa rivers. Taken from the Turks in the seventeenth century, Sombor was a Hungarian royal free town before World War I. Flour milling, match manufacturing, and trading in agricultural products are the principal economic activities in Sombor, which has rail connections with Subotica and Belgrade and with centers north in Hungary. Pop. 1948, 33,613. F. Sc.

**SOMERSET, EDWARD SEYMOUR, DUKE OF** (c. 1506-1552), Protector during the reign of Edward VI, was born about 1506 and educated at Oxford and Cambridge universities. He took part in an expedition to France in 1523 and came increasingly into favour with Henry VIII. In 1536, after his sister Jane Seymour's marriage to the king, he was made Viscount Beauchamp, and in 1537 he was created Earl of Hertford. He became lieutenant general in the north in 1544 and invaded Scotland, capturing and pillaging Edinburgh. During the next year, he played a brilliant part in the war against France and again invaded Scotland. Hertford was now the rival of the Catholic Duke of Norfolk for power, and when Edward VI succeeded to the throne (1547), it was Hertford, now the Duke of Somerset, who became Protector. However, his vigorous Protestant policy made him unpopular with many people. He defeated the Scottish army at Pinkie Cleugh but failed to secure the marriage of Edward to Mary, Queen of Scots. He sympathized with Kett's agricultural rebellion in East Anglia (1549), which alienated the landowners, and the conviction of his brother for treason further weakened his position. In January 1550 the Council deposed him as Protector and in October 1551 he was sent to the Tower of London on a concocted charge of treason backed by his bitter rival, the Earl of Warwick. He was tried, condemned, and executed on Tower Hill on Jan. 22, 1552. E. R. A.

*Tapestry-hung room at Montacute House, a fine stone manor house west of the town of Yeovil in Somersetshire. The house, now owned by the National Trust and open to the public, was built between 1580 and 1601 for Sir Edward Phelips by the noted Elizabethan architect John Thorpe.*

COURTESY OF THE TRAVEL ASSOCIATION

**SOMERSET,** a city in south central Kentucky, the county seat of Pulaski Co., situated 100 mi. southeast of Louisville, in an agricultural area where corn and tobacco are leading crops. Coal and timber are natural resources of the region. Somerset was made the county seat by court order in 1801. The city government is the mayor-council type. Transportation is provided by the Cincinnati, New Orleans & Texas Pacific Railway. Local industries include oil refining, flour milling, bottling, and the processing of dairy products. Pop. 1950, 7,097.

**SOMERSET,** a residential and resort village and town in southeastern Massachusetts, situated in Bristol Co., on the Taunton River, 40 mi. south of Boston. Founded in 1677, it was incorporated as a town in 1790. Somerset's government is the town-meeting type. Transportation is provided by the New York, New Haven and Hartford Railroad. Pop. 1950, (town) 8,566; (village) 4,296.

**SOMERSET,** a borough in the southwestern section of Pennsylvania, the county seat of Somerset Co., situated about 60 mi. southeast of Pittsburgh. The region is a rich anthracite coal district. Founded in 1795, Somerset was incorporated as a city in 1804. The borough government is the burgess-council type. President William McKinley maintained a summer "White House" in Somerset, which is a popular summer resort. Transportation is furnished by the Baltimore & Ohio Railroad, which maintains railroad shops in the borough. Building materials and wooden columns constitute the chief industrial products. Pop. 1950, 5,936.

**SOMERSETSHIRE** or **SOMERSET,** a maritime county in southwestern England, with an area of 1,620 sq. mi. It is bounded by the Bristol Channel on the north, the counties of Gloucester and Wiltshire on the east, Dorset and Devon on the south, and Devon on the west. The northern coast is low and marshy in the east; in the west it is lined with high slate cliffs. In the interior of the country is a series of hill ranges separated by the valleys or low, marshy flats. The chief ranges are the Mendip Hills, Polden Hills, Quantock Hills, Brendon Hills, and Exmoor. The Avon and the Parrett are the chief rivers. There are many orchards, and sheep and cattle are raised. There are coal measures in the northeastern part of the county, and the quarries of the famous Bath stone. In the west are the wild moorlands of Exmoor. The chief minerals are iron, manganese, and slate. The manufactures are woolens, gloves, lace, linens, and Bath brick. There are also pottery and printing works. Salmon and herring are caught in the Bristol Channel.

Caves, containing fine specimens of stalactites, stalagmites, and other rock formations, are found near Cheddar, world-famous for its cheese. Glastonbury owes its fame to the old ruined abbey, the history of which dates from an ancient church, said to be the first in England. It became a Benedictine abbey in 940. The remains of King Arthur and Queen Guinevere are supposed to have been discovered here in 1191 and reinterred in 1276. The present ruins date from the abbey which was built from 1185 to 1303 to replace the one that was burned in 1184. One of the finest cathedrals in England is at Wells, an attractive old city. Bath, the larg-

est town in Somerset and the most famous spa in England, is noted for the ruins of a Roman bath. The town has been written about by such famous authors as Jane Austen, Sheridan, Smollett, and Thackeray. Somerset sends six members to Parliament. Pop. 1952, 557,100. S. Van V.

**SOMERSWORTH** [sʌ′mərzwɜrth], a city in southeastern New Hampshire, situated in Strafford Co., on the Salmon Falls River, 33 mi. east of Concord, and opposite Berwick, Me., with which it is connected by bridge. The surrounding agricultural area is devoted principally to truck, dairy, and fruit farming. Somersworth was incorporated as a parish in 1729, as a town in 1754, and as a city in 1893. It was known at first as Great Falls. The city government is by mayor and council. A feature of the city is the Joseph Wentworth House, built in 1750. Transportation is supplied by the Boston and Maine Railroad. Local industries include woolen mills, shoe factories, and dye, bleaching, and bottling works. Pop. 1950, 6,927.

**SOMERVILLE** [sʌ′mərvɪl], a city in Middlesex Co., in eastern Massachusetts, just north of Cambridge and northwest of Boston. The community was founded as a part of Charlestown about 1630. The first ship built in Massachusetts was launched on the Mystic River in 1631 from Governor John Winthrop's farm on the city's site. On Prospect Hill, one of the community's seven hills, George Washington raised the first flag of the United Colonies on Jan. 1, 1776. The community was the scene of much activity during the Revolutionary War. Somerville was set off from Charlestown as an independent town in 1842, and it became a city in 1871. Of historic interest are Old Powder House and the Oliver Tufts House, which served as headquarters for General Charles Lee during the Revolutionary War. Tufts College is partially located in Somerville and partially in Medford. The Boston and Maine Railroad provides transportation. Somerville is an important wholesale distribution point. Slaughtering, meat packing, and the assembly of automobiles are the chief industries. Others produce foundry, brass, copper, paper, and glass products. Pop. 1950, 102,351.

**SOMERVILLE,** a borough in central New Jersey, the county seat of Somerset Co., situated 25 mi. southwest of Newark. There are numerous dairy and poultry farms in the surrounding district. Founded about 1690 and at first called Raritan, Somerville was made the county seat in 1783 and was incorporated as a borough in 1909. The borough government is by mayor and council. In the parsonage of the Dutch Reformed Church, built in 1751, Rev. John Frelinghuysen established the first Dutch Reformed Theological Seminary in America, which developed into Rutgers University at New Brunswick. Features of the borough are the Wallace House, headquarters of George Washington in the winter of 1778 to 1779, and the Somerville Hotel, which includes the Tunison Tavern built in 1770. Of additional interest is the James B. Duke estate near by. Transportation is provided by the Central Railroad of New Jersey. Local industries manufacture cast-iron pipe, lace for trimmings, soft drinks, and linoleum. Pop. 1950, 11,571.

**SOMME** [sɔ′m], a historic department in northwestern France, bounded by Pas-de-Calais and Nord departments on the north, Aisne on the east, Oise to the south, Seine-Inférieure on the southwest, and the English Channel on the west. It has an area of 2,443 sq. mi. The surface is a rolling plateau; the Somme is the largest river. Agriculture is the chief industry; wheat, oats, sugar beets, vegetables, and cider apples are the major crops. Pharmaceuticals, metallurgical products, phosphates, and textiles are manufactured. There are wide coastal sand dunes to the mouth of the Somme. Back of the dunes is land reclaimed from the sea by dikes. In the Bay of the Somme are the fishing ports of St.-Valéry-sur-Somme, Le Crotoy, and Le Hourdel. St.-Valéry is the port into which William the Conqueror was driven during his first attempt on England. Amiens, the prefecture, is the center of the French textile industry and has one of the largest cathedrals in France. The Ancre and Avre rivers join the Somme at Amiens. Amiens and many other places in the department were heavily damaged in World War II. Abbeville, Crécy, Ham, Montdidier, and Péronne are important historic towns. At Corbie are remains of a seventh-century abbey. The department was formed in 1790, largely from the old province of Picardy, of which Amiens was also capital. Pop. 1954, 464,153. S. Van V.

**SOMME** [sɔ′m], a river in northwestern France, 153 mi. long, flowing from the hills near St. Quentin to the English Channel. It enters the Channel by way of an estuary starting at Abbeville, and Amiens is the principal city along its course. The river is navigable and is connected by canal with the Seine-Oise river systems. The valley of the Somme was the scene of much fighting in World War I and again in World War II when German mechanized units advanced downstream to Abbeville to cut off the retreating British and French armies. S. Van V.

**SOMMER, FERDINAND** [zɔ′mər] (1875- ), German linguist, was born in Trier, May 4, 1875. He studied at Kassel, Freiburg (Baden), and Marburg, received the doctor's degree at Freiburg in 1896 and then continued his studies in Leipzig. He became *Privatdozent* at Leipzig in 1899 and professor at Basel in 1902. Thereafter he held professorships at Rostock, Jena, Bonn, and, since 1926, at Munich.

Sommer is one of the greatest living Indo-Europeanists, combining a wide range of knowledge with sound philological training and exactness of information. His best known work is the famous *Handbuch der lateinischen Laut-und Formenlehre* (1902), the most important book in the field and an essential tool for every Latinist. He has also published outstanding books on the Greek language including *Griechische Lautstudien* (1905) and *Sprachgeschichtliche Erläuterungen für den griechischen Unterricht* (1917); he has worked in the Lydian, Etruscan, and Baltic fields. His *Vergleichende Syntax der Schulsprachen* (*Deutsch, Französisch, Englisch, Lateinisch, Griechisch*) (1921), is excellent.

Sommer was one of the very few Indo-Europeanists who, immediately after the discovery of Cuneiform Hittite in 1917 by B. Hrozný, recognized the purely Indo-European character of the new language. Entering this new and difficult field, which seemed reserved to Assyriologists, he soon acquired a preëminent position in it and is now a recognized authority in Hittite philology as well as in Hittite linguistics. He has published many works on Hittite, some of a very sharp polemic character but all of great importance, among them *Die Ahhijavā-Urkunden* (1920), *Ahhijavā-frage und Sprachwissenschaft* (1934), and *Hethiter und Hethitisch* (1947). Since 1925 Sommer has directed the series *Hethitische Texte,* and from 1926 on (with A. Debrunner) the journals *Indogermanische Forschungen* and *Grundriss der Indogermanischen Sprach- und Altertumskunde* (Berlin); in 1927 he founded, with H. Ehelolf, the *Kleinasiatische Forschungen,* devoted mostly to Cuneiform Hittite. G. B.

**SOMMERFELT, ALF AXELSSON** [sɔ'mərfɛlt] (1892- ), Norwegian linguist, was born at Trondheim, Nov. 23, 1892. He studied in Oslo and abroad, received a French doctoral degree in Paris in 1921, became *Privatdozent* at Oslo in 1926, and was appointed professor of general linguistics at Oslo in 1931. Sommerfelt is one of the most distinguished Norwegian linguists; he is a member of the Scientific Academy in Oslo and was director from 1923 to 1940 of the Institut for Sammenlignede Kulturforskning. He has represented Norway in many international scholarly organizations, among them the Conseil Permanent de Linguistes, the Commission d'Enquête Linguistique, the Permanent Committee for the Organization of International Congresses of Phonetic Sciences, and, since 1945, the UNESCO.

A specialist in Celtic and Germanic linguistics, Sommerfelt has also been profoundly interested in problems of general linguistics. His book *La Langue et la société* (1936), which is devoted to an analysis of the language of one of the most primitive peoples of the world, the Aranta of central Australia, sums up all his previous studies in the field and reaches conclusions of the greatest importance. Dealing with the relationship between language and the mental level of the speaker, and therefore with the formation and evolution of language and linguistic categories in general, it is a fundamental work for all studies of this kind. More popular works by Sommerfelt include *Hvordan sproget til* (1934), *Sproget som samfundsorgan* (1935), and *Hva er rase?* (1939). In 1942 he published, in English, *The Written and Spoken Word in Norway*. Sommerfelt has also published a number of specialized linguistic studies, made important contributions to scholarly journals, and since 1923 has been editing, with Prof. Trygve Knudsen, a dictionary of the *riksmål*.

G. B.

**SOMNAMBULISM,** sleepwalking, a dissociated state, manifested by automatic motor activity during sleep.

Adequate statistical data on sleepwalking are lacking, but it is generally recognized that the phenomenon is fairly frequent in childhood and disappears, as a rule, during adolescence. Incidence in adults, however, is considerably greater than is generally believed. Somnambulism may occur in otherwise apparently normal children and healthy adults, but in the adults it is more often associated with epileptic, chronic alcoholic, and psychotic conditions.

Popular legend assumes that sleepwalkers move in a state of deep sleep, with their eyes closed, yet skillfully avoiding all obstacles and never coming to any harm, unless roughly and suddenly awakened. This assumption is incorrect. Except for the comparatively rare cases of post-epileptic automatism, sleepwalkers are in a state of incomplete sleep, with their eyes open and pupils dilated and reacting to light. Although they may walk for miles, without injuring themselves, unfortunate accidents are frequent. The most common type of sleepwalking, caused by acute anxiety, often following traumatic battle experiences, is manifested by aggressive tendencies during the sleepwalking stage. The patients often injure themselves and others, and seem to be in a state of terror. They perspire profusely; have tense, rigid muscles; and have rapid, shallow respiration. They resist attempts to lead them back to bed, talk incoherently, but do not answer questions. Upon waking, there is no recollection of the experience.

Chronic anxiety sometimes results in a different type of somnambulism. Attacks are less frequent and less violent. Patients walk aimlessly for one or two miles before returning to bed, but their movements are slow, arms relaxed, and respiration quiet and regular.

B. Van R.

**SOMNUS** [sɒ'mnəs], the personification of sleep, identified by the Romans with Hypnos and hence the brother of Death and son of Night. *See also* Hypnos.

G. E. D.

**SONATA** [sonɑ'tə], an extended musical composition in one or more movements, for one or more instruments.

**History.** The word "sonata" (from the Italian *sonare,* "to sound") has undergone numerous refinements and changes in meaning since it was first used in Italy in the late sixteenth century to refer merely to any instrumental or "sound" piece as opposed to the *canzone* or *cantata,* which referred to a piece that was sung.

*The Baroque Sonata.* In the course of the seventeenth century the term "sonata" came to be identified chiefly with the music for small string ensembles whose sections were expanded into separate, contrasting movements; it was thus commonly used with reference to the music written for two violins and bass that was known subsequently as the "trio sonata." Notable exceptions to this practice were the organ sonata and the "sonata," or introductory movement in the German suite for wind instruments. In Italy, two somewhat interdependent types grew out of the instrumental *canzone* and the suite. These were the *sonata da chiesa,* or church sonata, which consisted typically of a homophonic slow movement, a fugal allegro, a brief transitional adagio, and a giguelike finale, and the *sonata da camera,* or chamber sonata, which consisted of a freer assortment of idealized dance forms, especially the allemande, courante, saraband, and gigue.

At the end of the seventeenth century, these types reached a peak of development in Italy in the trio and the accompanied violin sonatas of Arcangelo Corelli. At the same time, they were taken up by Heinrich Biber in Germany, Henry Purcell in England, and Couperin le Grand in France, all of whom modified them. Further important and extensive additions to this literature, now become international in style and of a uniformly high quality, were made by Bach, Handel, Gluck, Tartini, Jean Marie Leclair, William Boyce, and many others during the first six decades of the eighteenth century. The solo keyboard sonata, pioneered chiefly by Bernardo Pasquini and Johann Kuhnau at the end of the seventeenth century, received comparatively little attention at the hands of Bach and his contemporaries; for the most part it was adapted from the church and chamber types, but especially interesting were some 550 one-movement étude-like pieces, called "sonatas" as well as "exercies," by Domenico Scarlatti. Special mention must also be made of Bach's extraordinarily rich sonatas for solo violin and solo violincello.

*The Classical Sonata.* The Classical Viennese sonata, with its fluent homophony, structural symmetry, and dramatic contrasts, developed from the earlier sonata and reached its height at the end of the eighteenth century in the works of Haydn, Mozart, and Beethoven. The word "sonata" now came to be restricted to music for the newly popular piano or other solo instrument, with or without accompaniment. Music resembling the sonata but scored for a greater number of instruments was called, according to the ensemble that played it, a trio, a quartet, or a symphony. With Beethoven the sonata achieved an inexorable logic and a dramatic drive never surpassed. This is particularly true of his thirty-eight piano sonatas, of which the Pathétique, the Moonlight, and the Appassionata have the accepted stature of masterworks. Beethoven explored and utilized the various resources of the sonata form so thoroughly that he marked at once the culmination and the dissolution of the Classical sonata

idea, and in spite of unusually beautiful harmonies and melodies and wonderfully dramatic episodes, uneven quality has prevented most of the solo and duet sonatas of his immediate successor, Schubert, from achieving the general popularity they otherwise deserve.

*The Romantic and Twentieth-Century Sonata.* The four piano sonatas by Weber and the three each by Mendelssohn, Chopin, and Schumann, all composed before 1845, indicate at a glance that wealth and intimacy of harmony and melody were taking precedence over the strict economy and logic of balanced form in the Romantic Era, this notwithstanding the fact that their composers made a self-conscious effort to emulate the Classicists in this form. A distinguished and wholly Romantic exception is Liszt's B minor piano sonata (1854), which combines all the movements into one. On the other hand, the ten sonatas written variously for piano, violin and piano, violincello and piano, and clarinet and piano by Brahms (1833-1897) present a genuine extension of the Classical principles of form during the Romantic Era.

In the large number of sonatas that continued to appear around the end of the nineteenth century, the competent but slavish adherence to an overly formal concept of the Classical sonata is belied by the thoroughly Romantic and often nationalistic content. An important evidence of the desire for an ever-greater unity between the several movements of Romantic sonata music, a unity accomplished by Beethoven through inner stylistic and expressive kinship, was the time-honored and overt principle of reiterating the same idea from movement to movement, often with programmatic implications. Such, for example, was a main purpose of Franck's cyclic form which can be observed in his popular violin and piano sonata (1886).

The lasting validity of the Classical sonata idea is demonstrated by the fact that nearly every important twentieth-century composer has resorted to it in some of his major instrumental works. Compact terseness, as in Prokofiev, has often supplanted effusive Romantic prolixity, while the innovations of original tonal systems, as in Hindemith, has replaced cyclic procedures. Yet beneath these tendencies the basic regimen of the Classical sonata has continued to be operative.

**Sonata Form.** Sonata (or sonata-allegro, or first-movement) form is the name given to the special ternary design used almost invariably since the Classical Era in one or more movements of the sonata, symphony, concerto, and frequently the overture; it is also used in the trio, quartet, quintet, and other types of chamber music. In this form, two or more themes, separated by bridge passages and contrasted in character and tonality, are typically introduced in the exposition or first section of this design and usually repeated. These themes are then exploited at the composer's discretion, through extension, reiteration, dissection, and modulation, in the development, or second, section. In the recapitulation, or third, section they are finally restated so as to conclude in the original key, and the entire sonata sometimes ends with an added coda. The cumulative tension thus created by the thematic contrasts and the climactic development and the release accomplished by the restatement of the themes in the light of their foregoing development is of great musical appeal, and the lasting validity of this general form is indicated by its use in nearly all types of music.

While chance examples of sonata form occur sporadically in the Baroque sonata movements and with increasing frequency throughout the eighteenth century, the form did not become categorized until the nineteenth-century theorists classified it. Since then it has been a point of departure for innovations of varying consequence. Although the designations "masculine" and "feminine" for the principal themes are of Romantic origin, the Romantic sonata often sacrifices the tension of thematic contrast and development to a more static and even disruptive lyricism. An interesting tendency, evident especially among the later symphonists, such as Bruckner, Sibelius, and Shostakovich, and certainly anticipated by Beethoven in the third and fifth symphonies, is the use of germ ideas that are developed and expanded to the status of full themes during the entire course of the sonata form rather than in the central section alone. This tendency may account for the greatly curtailed recapitulation in many twentieth-century examples of the sonata form, since the continual development of the ideas makes their full restatement superfluous. W. S. N.

**SONATINA** [so′nɑti′nə] (lit. "little sonata"), a form of musical composition, usually for piano, having fewer and shorter movements than the full sonata; it is also somewhat less developed formally than the fuller form and is easier to play. Such sonatinas as those of Muzio Clementi were designed primarily as teaching pieces; Busoni and Ravel, on the other hand, wrote sonatinas which, although they were abbreviated in form, were technically as difficult and artistically as substantial as any ordinary sonata. The term "sonatina form" has occasionally been applied to "sonata allegro" movements, in which the exposition and recapitulation sections are connected by a brief transition rather than by a true development section. W. Li.

**SØNDERBORG** [sö′nərbɔrχ], a city on the island of Als, off the southeast coast of Jutland, Denmark. A bathing resort and the commercial center of the island, Sønderborg is 110 mi. southwest of Copenhagen, in an area of fertile farms on glacial moraine and outwash. The town, first settled in the thirteenth century, is located on both sides of the Alsensund, which separates the island of Als and the mainland of Nord Slesvig, Denmark. The near-by castle, built by Waldemar the Great in the twelfth century, was the scene of the imprisonment (1532-1549) of King Christian II and now serves as a museum for relics of the Second Slesvig War and other articles. This war was brought to an end by the defeat of Denmark by Germany at Dybböl Hill, near the town, in 1864. At that time the town, which was burned, was ceded with the rest of Nord Slesvig to Germany. In 1920 the area was returned to Denmark by plebiscite, and the Crown Prince established his summer home at near-by Graasten Castle. Pop. 1953, 16,571. J. E. V.

**SONDRIO** [sɔ′ndrio], a province and its capital located in the Valtellina in northern Lombardy, northern Italy.

**The City.** Situated at 46° 10′ N. lat., 9° 50′ E. long., Sondrio lies at an elevation of 940 ft. above sea level on the small Mallero River just above its confluence with the Adda. The city is a small commercial and industrial center of local importance. Sondrio has seldom played a vital role in history. During the Thirty Years' War, the strategically located Valtellina was much fought over by French, Spanish, Austrian and other armies. Pop. (off. est.) 1947, 13,836.

**The Province.** Sondrio, comprising 79 communes, has an area of 1,239 sq. mi. with a population density of 115 per sq. mi., one of the lowest in Italy. In recent years the population has declined because of extensive emigration from the mountain communes to the Lombard Plain and elsewhere. The province consists of the Italian part of the Adda River

valley above Lake Como, plus the upper reaches of the Livigno Valley. On practically all sides it is bounded by high mountains, including the Bergamo Alps on the south. Agriculture and stockraising are the leading occupations. Recently industries have made a small beginning in metallurgy, textiles, and woodwork. Pop. (off. est. 1947), 153,000.

R. G. W.

**SONG,** in the usual general sense of the term, the musical utterance of men. No group of men has ever been found to whom song is entirely unknown. Among primitive peoples two kinds of song exist; the commonest is a chant closely related to speech and using prose rhythms with but few tones, while the other is an accented type, inseparable from the dance.

Song serves a variety of purposes in human society. Many peoples believe that it possesses magic efficacy, and songs have always been widely used to express religious exaltation, praise, or petition to some great power. In the feudal period, songs were newsbearing chants, and ballads based on actual events are still composed in many parts of the world, including the mountain regions of North America, where accounts of Charles Lindbergh's flight and the sinking of the *Titanic* have had an enduring popularity. Songs are also used to lighten labor by facilitating the rhythmic co-ordination of movements; for example, sea chanteys and the track-laying chants of the railroad construction gangs add to both the ease and the efficiency of the work that they accompany, and their usefulness has been so well recognized that on sailing ships a good chanteyman used to be paid more than his fellow sailors. Again, certain kinds of songs are used instead of instruments to accompany dancing, as lilting in Ireland, "mouth music" in the Hebrides, and play-party songs in the United States.

The art song appears very early in the history of mankind. A combination of expressive poetry and melody, often accompanied by an instrument, it is composed primarily either for pure pleasure in song or to express some personal human emotion such as love, grief, or joy; this form of song is not intended for any special ritual or social use. Usually a song is the musical setting of a poem, either accompanied by a musical instrument or intended for the voice alone; but musical settings of nonsense syllables are not uncommon, and several composers have written pieces, called *vocalises,* which are intended for wordless singing. The popular songs which have a brief but intense existence on juke box and radio may be described as a commercial form of the art song.

It is now generally recognized that the old theory of the "communal composition of song" is erroneous and that all creative activity of this sort, in which a group participates, depends not on any mystical act of participation but upon a folk leader, who is to a greater or less degree a poet and composer. The typical process by which group songs are composed may be observed in many parts of the world. Among the Portuguese, for example, the *fado* is a type of song that allows the individuals of a group to take turns improvising successive stanzas. In practice, however, this improvisation quickly becomes the prerogative of the readiest singers; the variants produced by these more gifted members of the group soon become traditional; and these variants are repeated by others unable to compose their own. Many repetitions in the oral tradition simplify the original material to a greater or less degree, and in the course of time this erosion produces what we call a folk song, marked unconsciously by the taste and characteristics of a people.

There is every reason to believe that the individual composition of a solo song is a very old institution indeed, and not the product, as many writers in the late nineteenth and early twentieth centuries confidently asserted, of any given moment in the short span of Western musical culture. A spectacular example of a solo song that antedates the Christian era is the Chinese melody called *Peachblossom,* thought to be thousands of years old. It first appears in written records in China before the birth of Christ, at a time when the Chinese devices for indicating relative pitches were already sufficiently accurate to indicate the outline of the tune. Variants of this same tune are familiar to most of the 400,000,000 inhabitants of modern China, and therefore it is probably safe to say that this is the most popular song ever known.

In European music, the first great flowering of song of which ample records exist is that which took place in France around A.D. 1100. The troubadours in the south of France and the trouvères in the north were the aristocrats among professional musicians of this period. They were both composers and performers, usually attached to one or another of the great houses of western Europe. The names of many of these artists are still known, and hundreds of their compositions have survived, usually solo songs influenced by the melodic and rhythmic modes of the medieval church. At first these singers composed both words and music and played their own accompaniments; later, however, the functions of poet and musician separated. The troubadours had a popular counterpart in the jongleurs and *ménétriers,* or minstrels, who combined various kinds of acrobatics and juggling with their roles as traveling musicians. They were succeeded in central Europe by the minnesingers, who differed from the troubadours in their insistence upon singing their own verses and in their refusal to be paid for their songs. By the beginning of the fourteenth century, however, professional music in Germany was in the hands of the Meistersinger, middleclass guildsmen who flourished as feudalism began to decline. By this time, also, many of the songs, whose forms (ballade, rondeau, madrigal, etc.) were as numerous as those of poetry and were closely related to them in structure, were set down with indications for an accompaniment to the solo voice.

By the middle of the fifteenth century the composers of northern Europe were absorbed in the writing of polyphonic music, and lyrical solo songs seem to have been rare in cultivated musical circles for a hundred years. With the songs of the lutanists in sixteenth-century England and Spain, however, a great revival of song occurred which reached heights never surpassed in either country. Meanwhile, the movement in Italy which resulted, about 1600, in the first opera, was developing two distinct types of song, the recitative and the aria. The recitative was close to speech and was used to carry the plot forward wherever it was important to understand the words; the interest in the aria, on the other hand, lay chiefly in the melody. The former style had great influence on French music, as the aria did on Italian. These types of song also influenced vocal style, and thus in the nineteenth and twentieth centuries Italian singers were famous for a flowing style which emphasized great beauty of tone, whereas French singers had developed a quite different use of the voice, coloring the words with intonations of great expressiveness.

By the end of the eighteenth century, several influences in central Europe had combined to bring about the great period of German song. Up to this time, song accompaniments for keyboard instruments usually made use of the figured bass system, which defined the harmonies intended by the composer but left the detail of their arrangement on the keyboard and their progression from one harmony to another

to the performer. Now, however, composers began to interest themselves in a new type of accompaniment, which soon ceased to be designed simply for the occasional support of the singer. The improved fullness and sustained qualities of tone that accompanied the development of the piano made more interesting the composition of music specifically for the piano, and the result was a series of songs described as *durchkomponiert,* or through-composed; that is, the music was composed to fit the song all the way through, and though the melody for successive stanzas was usually the same, the accompaniment was intended to heighten the dramatic effect of the words and to be more nearly equal in importance to the voice. Songs written in this general style are called *Lieder.* The word *Lied* is simply the German for "song," but the term has come to mean a certain kind of comparatively dramatic song with piano accompaniment.

Some modern composers have experimented with a style called *Sprechgesang,* or "speech song," which may be described as a singing that resembles speech. There is also a new type of recitative that is occasionally heard, called *Sprechstimme,* or "speech voice," which is speech with a singing quality and differs from primitive chants chiefly in its wide melodic leaps. *See also* Music; Singing. H. Cow.

**SONGDO.** *See* Kaesŏng.

**SONG FORM,** in music, a loose though well-established designation for that three-part or A-B-A structure in which a complete section is repeated after a contrasting digression. Song form is so named because it represents a design frequently found in the art song, though the A-B-A design, one of the oldest and most fundamental designs in music, is equally common in instrumental music. It is the design, for example, of the minuet with trio, the scherzo with one trio, and, indeed, of most of the smaller forms popularized during the Romantic period: the étude, waltz, mazurka, polonaise, romance, and nocturne.

The first of the three sections of the song form may end with a full cadence or it may dissolve by degrees into the digression. The latter may offer a diametric contrast in style, meter, key, and texture, or it may simply present a new facet of the initial idea. Finally, the initial section may be repeated literally, or it may be altered by additions, deletions, or ornamental treatment. In a broad sense, sonata form is an extended elaboration of song form. W. S. N.

**SONGHAI.** *See* African Peoples.

**SONGKOI** or **COI RIVER** [sɔ′ŋkɔi′], a river also known as Red River, rising in the south central part of Yunan province of southwestern China. It flows almost a straight course, through what is thought to be a structural valley, southeastward across Tonkin, northern French Indochina, into the Gulf of Tonkin, a distance of about 500 mi. Hanoi, Indochina, is the principal city on the river.

J. E. F.

**SONG OF HIAWATHA.** *See* Hiawatha, The Song of.

**SONG OF ROLAND, THE.** *See* Chanson de Roland, La.

**SONG OF SOLOMON,** also called Song of Songs and Canticles, a book of the Old Testament, belonging to the division of Hagiographa (Sacred Writings). It is one of the five scrolls and is read in the synagogue during the Passover holiday.

The Song of Solomon is a rhapsodic poem, or a series of love poems, expressing the desire of a young woman for her lover and the young man's responding passion. From very early times, the work has been traditionally regarded as an allegory, representing the love between God and Israel, and in fact, the conception of the relationship between God and Israel as a marriage is expressed in the early prophetic books of the Old Testament. It was doubtless on the strength of this interpretation and its ascription to the authorship of Solomon that the book gained admission to the canon; even so it was the subject of considerable dispute, some sages, while not denying that the work was allegorical, holding that its highly erotic character might prove a pitfall for unlearned readers. The Christian Church has similarly interpreted the Song of Songs symbolically, seeing it as a prophetic representation of the love between Christ and the Church.

Most modern critics hold that the poem is just what it appears to be—a glorification of earthly love. Even literally interpreted, however, the book presents many problems, and a number of explanatory theories have been advanced. While it is evident that the lines are spoken by more than one person, it is not certain how many persons are involved or what situation is depicted. Many critics see the work as a drama, and among the interpretations offered are the following: a young shepherd and shepherdess find fulfillment in married love; the king falls in love with a shepherd girl, but she remains faithful to her shepherd and is ultimately united with him; the king falls in love with a humble shepherd girl and elevates her to the position of queen. Those who do not regard the king as a participant in the action, explain the references to him on the basis of the oriental convention of calling a bridegroom a king. A theory which has gained ground in recent times is that the Song of Songs is a series of wedding songs sung at the celebration of a marriage feast; this removes the difficulty raised by the lack of continuity.

Whatever interpretation of the Song of Songs is accepted, the work is notable for its depth of passion and vivid sensualism, its effective imagery in which love is intimately associated with the beauties of nature, and its many exquisite phrases which have widely influenced language and literature. A notable Hebrew Sabbath hymn, for example, in which the Sabbath is likened to a bride, uses as a refrain the phrase *Lecha dodi* ("come, my beloved," vii:11).

It was formerly supposed by scholars that the Song of Solomon was, if not Solomonic, at least very early in date, but most critics have come to believe, on the basis of linguistic evidence, that it is of a comparatively late date; a precise date, however, has not been established. Some see in the work the evidence of Greek influence; this would suggest a date in the third or second century B.C. D. G. and G. W.

**SONG OF THE THREE HOLY CHILDREN, THE,** an Apocryphal book, consisting of three sections: The Prayer of Azarias, a brief narrative passage, and The Hymn of the Three. It is found only in the Greek Bible, and versions based upon it, but some scholars believe that it was originally written in Hebrew. In the versions in which it appears, the work, constituting an addition to the Book of Daniel, is inserted after iii:23 in that book. The Prayer purports to be a plea for deliverance from the fiery furnace into which Azarias or Azariah (Abednego) and his two companions, Hananiah (Shadrach) and Meshael (Meshach) have been cast by Nebuchadnezzar's orders; the narrative passage tells of the descent of an angel who delivers the three by cooling the center of the furnace; and the Hymn is the thanksgiving ode of the three.

It has been pointed out that both the Prayer and the Hymn seem unsuited to the situation: the first is a confession of national sin, an acknowledgment of the justice of the punishment, and a complaint of its bitterness; the second is a doxology, couched in general terms and closely resembling Psalm cxlviii, calling on all natural phenomena to join in the praise of the Lord. Accordingly scholars hold that the Prayer and the Hymn were never an organic part of the Book of Daniel, but that these, as well as the narrative passage, were later interpolated in a desire to expand the popular Daniel story. Internal evidence in the Prayer suggests the difficult period of the Maccabean revolt as the time of composition (c. 167 B.C.); the Hymn was probably composed some time later when conditions were improved. D. G. and G. W.

**SONNECK, OSCAR GEORGE THEODORE** [sa′-nɛk] (1873-1928), pioneer American musicologist, and first chief of the music division of the Library of Congress (Washington, D.C.), was born Oct. 6, 1873, at Jersey City, N.J. After a German education he returned to this country and began the researches in early American music which resulted in his many publications. *Early Concert Life in America* (1907), *Early Opera in America* (1915), and other studies by Sonneck painted for the first time a balanced and detailed picture of musical life in America before 1800. Appointed in 1902 to head the newly-organized music division of the Library of Congress, he created within the space of fifteen years one of the foremost music libraries of the world. In 1915 he founded and assumed editorship of *The Musical Quarterly,* America's first musicological journal, and from 1917 until his death he was a director of the music publishing firm of G. Schirmer, Inc. He died Oct. 30, 1928, in New York City. W. Li.

**SONNET,** a poem composed normally of fourteen lines of iambic pentameter rhymed according to a traditional scheme. The exact origin of the form is obscure, but it was well known in Italy in the thirteenth century and since that time has attained wide and permanent popularity in all the Western European literatures. Different groupings of the lines and different rhyme schemes have produced several distinct forms, of which two are common in English, although poets frequently experiment with variations.

Of the two standard patterns, the "Italian" or "Petrarchan" sonnet produces the more serene effect, one that is well illustrated in Wordsworth's *Westminster Bridge:*

> Earth has not anything to show more fair:
> Dull would he be of soul who could pass by
> A sight so touching in its majesty:
> This city now doth, like a garment, wear
> The beauty of the morning; silent, bare,
> Ships, towers, domes, theatres, and temples lie
> Open unto the fields, and to the sky;
> All bright and glittering in the smokeless air.
> Never did sun more beautifully steep
> In his first splendour, valley, rock, or hill;
> Ne'er saw I, never felt, a calm so deep!
> The river glideth at his own sweet will:
> Dear God! the very houses seem asleep;
> And all that mighty heart is lying still!

In the Italian sonnet the lines are arranged in two groups: the first group (the octave) contains eight lines closely knit together by the rhyme scheme *abbaabba;* the second group (the sestet) contains the six remaining lines in a rhyme scheme that is commonly *cdecde,* although many variations, especially *cdcdcd* as above, are used. The Italian sonnet is particularly appropriate for philosophic poems and for eloquent love poems; its natural pause after the octave makes it a logical form for the expression of two closely related ideas. In the best Italian sonnets, the rhythm normally builds to a climax at the end of the octave, and dies away to silence in the closing lines of the sestet.

The other common form is the "English" or "Shakespearean" sonnet:

> That time of year thou mayst in me behold
> When yellow leaves, or none, or few, do hang
> Upon those boughs which shake against the cold,
> Bare ruin'd choirs where late the sweet birds sang.
> In me thou see'st the twilight of such day
> As after sunset fadeth in the west,
> Which by and by black night doth take away,
> Death's second self, that seals up all in rest.
> In me thou see'st the glowing of such fire
> That on the ashes of his youth doth lie,
> As the death-bed whereon it must expire,
> Consum'd with that which it was nourish'd by.
> This thou perceiv'st, which makes thy love more strong,
> To love that well which thou must leave ere long.

Here the fourteen lines are treated as three quatrains and a couplet, so that the form lends itself particularly to the expression of three closely related ideas about the same theme, with a brief concluding statement. The rhyme scheme accentuates this grouping, being *abab cdcd efef gg.* Characteristically, there is a slight pause at the end of each quatrain, so that the rhythm does not have the single rise and fall that is heard in the Italian sonnet. Shakespeare is the great master of the English sonnet, a form that has continued to attract most serious poets since his time.

The sonnet sequence or cycle is a group of sonnets developing one central theme, usually love, and published as a unit. After Petrarch's great model (*Sonnets to Laura*) many cycles have been produced, the fashion having been particularly popular in English. The best-known examples are Platen's *Sonnette aus Venedig* (in German), Spenser's *Amoretti,* Sidney's *Astrophel and Stella,* Samuel Daniel's *Delia,* Shakespeare's *Sonnets,* Elizabeth Barrett Browning's *Sonnets from the Portuguese,* Dante Gabriel Rossetti's *House of Life,* and, in America, Edna St. Vincent Millay's *Fatal Interview* and William Ellery Leonard's *Two Lives.* R. Bn.

**SONORA** [sono′rə], a mountain pass 9,624 ft. high, located in Tuolumne Co. in the Sierra Nevadas of eastern California. It received its name from the near-by town of Sonora, which was a central point on the wagon trail used by the early explorers, miners, and immigrants in reaching the San Joaquin Valley. The pass, which was first used for the gold rush in 1853, was of major importance as a Sierra crossing during the 1860's. A. L. R.

**SONS AND LOVERS,** a vivid and poetically written autobiographical novel by D. H. Lawrence, first published in 1913. Composed before the study of modern abnormal psychology had reached an advanced stage, it constitutes, nevertheless, a classic literary investigation into the disastrous effect of an exaggerated emotional attachment between mother and son. Suffering from the effects of an unhappy marriage and the drabness of a poverty-ridden life in a coal-mining village, Mrs. Morel is driven to seek compensation for the disappointments of her own life in her influence upon her younger son, Paul, who finds this influence an unsurmountable barrier in his attempts to approach other women, whether spiritually or passionately. Only his mother's death frees him to make his own long-belated adjustment to the world and to himself. C. E. M.

**SONS OF LIBERTY,** the name of two underground political organizations which operated at different periods in American history.

1. The first Sons of Liberty was an intercolonial secret organization of the more radical groups in the American colonies after 1763. It appeared openly at the time of the Stamp Act. Its members helped lead the successful effort to force the stamp agents to resign in Boston and in New York. In the following years they were effective in forcing nonimportation agreements on American merchants. Sons of Liberty in the various colonies maintained contact by means of messengers. From time to time they took joint action against British measures. The organization appears to have been led by merchants, lawyers, and politicians, but included the masses of mechanics and artisans in the colonial towns. The masses sometimes got out of hand, rioted, and destroyed property. In 1765 the residence of Chief Justice Thomas Hutchinson in Boston was destroyed. In New York City houses of British officials were attacked, taverns were raided, and general riots followed. These violent methods alienated many merchants and other members, but there remained a small, well-organized group of leaders. This unit provided a solid basis for the revolutionary movement, which grew rapidly after the passage of the "Intolerable Acts" in 1774.

2. The second Sons of Liberty, a Copperhead order, was formed in 1864 during the Civil War as a result of the reorganization of the Order of the American Knights. C. L. Vallandigham of Ohio, then in exile in Canada, was the Supreme Commander. The order, at one time claiming a membership of 300,000, was organized to work for peace. Members were sworn to oppose the confiscation acts of the Federal Government and to support states' rights principles. They opposed the draft and discouraged enlistments in the Northern armies. Confederate agents in Canada used the order without success to promote a northwestern confederacy outside the Union. Six of its members were arrested and tried for treason, and three were condemned to death, but were never executed. M. Je.

**SONS OF THE AMERICAN REVOLUTION, THE NATIONAL SOCIETY OF.** *See* Societies, Associations, and Organizations.

**SONSONATE** [sɔ′nsonɑ′te], capital of the department of the same name, situated about 50 mi. from San Salvador and 12 mi. from Acajutla, near the volcano of Izalco, in El Salvador. It is the center of a rich agricultural district, which produces sugar, coffee, corn, tobacco, and balsam. Pop. 1950, 17,949. S. G. I.

**SOOCHOW (WUHSIEN)** [su′jo′, wu′shɪɛ′n], a city in the southern part of the Province of Kiangsu of central eastern China, to the east of Tai Lake, at 31° 15′ N. lat. and 120° 32′ E. long. Soochow is situated on the level, low-lying Yangtze delta, about 50 mi. west of Shanghai, although the Yangtze itself is 20 mi. north of Soochow. Near the city the Grand Canal takes a sharp turn toward the south, extending another 200 mi. down to Hangchow in Chekiang Province. Surrounded by a wall and a moat 12 mi. in circumference, Soochow was the capital of the local Kingdom of Wu about 600 B.C.—not to be confused with the later Kingdom of Wu (A.D. 222-280)—hence the alternate name Wuhsien. It was during the Sui Dynasty (A.D. 589-618) that the city was first known as Soochow.

Scores of canals cut through Soochow and in many cases take the place of streets, though many now have either been filled in or replaced by streets. Many of the ancient marble and carved stone bridges seen by Marco Polo, who counted 6,000 of them, are no longer in existence. The Tiger Hill Pagoda, built in A.D. 601 and rebuilt in 1438, is now in danger of collapse. The 1,000-year-old Taoist shrine, Shuen Miao Kwan, has now become a market place, but is still held sacred by Taoists. The Pao Tai Chiao, or the Precious Belt Bridge, 12,000 ft. long, which spans a stream connecting the Grand Canal with the Tai Hu or Great Lake, was built in the ninth century by a local official. In Soochow is Soochow (Tungwu) University, which is noted for its law school.

The climate of Soochow is warm and humid for much of the year, the average temperature being about 60° F.; June, July, and August average about 80° F. with a maximum temperature of 105° F. The three winter months of December, January, and February average about 38° F. Soochow has from 45 to 50 in. of rainfall annually, fairly evenly distributed but with a maximum of from 6 to 7 in. in June and July.

The area surrounding Soochow is thickly populated. A variety of agricultural products such as rice, cotton, beans, mulberry trees, wheat, tea, and vegetables are grown. There are food-processing establishments and textile mills in Soochow, the most important products being tea, cotton, and silk. Soochow is said to produce both the best rice and the best silk in China. The most important industry of the city is silk reeling. There are about 4,000 hand looms in operation, producing the finest brocade and silk gauze. Excellent embroideries, known as "Ku Hsiu" as distinguished from the "Hsiang Hsiu" of Changsha, are also produced in large quantities. Other important occupations are jade stone-cutting and grinding natural crystals into spectacle lenses. Soochow is on the Shanghai-Nanking Railway. Pop. (est. 1947), 260,000. A. C. T.

**SOONG, T. V. (SUNG TSE-VEN)** [sʊ′ŋ] (1891- ), Chinese banker and politician, was born in Shanghai in 1891. He was one of six children of an influential Chinese family; three sisters were married to Sun Yat-sen, Chiang Kai-shek, and H. H. Kung. Soong had his early schooling in Shanghai, then graduated from Harvard University and received a doctorate from Columbia University. After working in New York banking houses he returned to China in 1917 and rose rapidly in banking and politics. He was secretary of the Canton government in 1923, president of the Canton Central Bank in 1924, and minister of finance in the Nationalist government from 1925 to 1933. In 1933, for the first time in modern Chinese history, Soong balanced the country's budget without recourse to foreign loans. He unified the currency, abolished domestic tariffs, established central banking, and introduced other Western financial reforms. He founded the Bank of China and became its chairman in 1935. Soong was appointed minister of foreign affairs in 1941, and in 1944 he became acting premier and president of the Executive Yuan, second in importance only to Generalissimo Chiang Kai-shek. On May 31, 1945, he succeeded to the premiership when Chiang resigned in order to devote himself to other duties, remaining in that post until February 1947. After the Communist victory in the Chinese civil war, Soong arrived in the United States. He later went to Paris. On June 16, 1950, Chiang Kai-shek ousted both T. V. Soong and Dr. H. H. Kung as bank directors. Soong returned to the United States in July 1950. G. Q.

**SOPHISTS** [sɒ′fɪsts], a term originally denoting "men of wisdom." During the second half of the fifth century B.C.

the term came to be applied to the professional teachers in Greece who traveled about giving instruction in the arts of rhetoric, oratory, and the conduct of public affairs. The name gradually became a term of reproach, partly because the sophists took pay and partly because the radicalism of some of the later sophists scandalized the conservatives. Contrary to the traditional view, the sophists were not a clearly defined school or sect, with a recognized or common type of philosophical doctrine. They were characterized more by their mode of thought than by any fixed content of thought. However, though they made no pretense of being philosophers, their influence on philosophy, as well as on politics and ethics, was considerable; and their stress on dialectic, grammar, rhetoric, and oratory was of lasting value in the field of literary education.

In the history of philosophy the sophists mark the end of the era which preceded Socrates, but in actual fact they belonged neither to the pre-Socratic era of the Atomistic, Heraclitean, and Eleatic schools, nor to the later era of Socratic idealism. They represent, more correctly, a short pause in the development of philosophy, during which all Greek traditions and beliefs fell prey to the critical spirit of the age, and the stage was cleared for the second great period in Greek philosophical thought, which reached its highest development in Socrates, Plato, and Aristotle.

Sophistic skepticism was the outcome of a complex mixture of influences which shaped the social, political, philosophical, and religious conditions of Athens during the latter half of the 5th century B.C. The sophists sprang up as the result of a clear demand for a certain kind of culture, especially in the art of public speaking, proficiency in which, with the rise of Athenian democracy, became of paramount importance for those seeking success in civic affairs. This emphasis on worldly success tended to corrupt, and the later sophists became increasingly unscrupulous, setting no value on objective truth, making the worse seem the better cause, and teaching their pupils only how to win at all costs and by whatsoever means. However, no reproach of the sort was ever attached to the two leading philosophers of the sophistic age, Protagoras and Gorgias, though their doctrines led inevitably to moral, philosophical, and intellectual decay. Protagoras of Abdera (c. 480-411 B.C.), in the famous phrase attributed to him—"Man is the measure of all things"—denied objective truth and reduced knowledge to individual opinion, thus laying the foundation of the eristic method of dispute and, by making the subjective element everything in knowledge, turning attention from external nature to man himself. Gorgias of Leontini, a contemporary of Protagoras, proved by the use of dialectical reasoning that nothing exists, that even if it did exist it could not be known, and that if it could be known it could never be communicated, thus carrying the skepticism of Protagoras to nihilism. Hippias of Elis, the versatile rhetorician, and Prodicus of Ceos, the moralist, exemplified the logical limits of eristic and moral sophistry, the attempts of the latter to formulate moral precepts breaking down under skepticism, for, where truth is relative, laws become meaningless.

From this theoretical skepticism, in which the individual was a law unto himself in matters of knowledge, the step was not far to ethical skepticism and the view that man was a law unto himself in matters of conduct. It was left to the younger and more radical of the sophists—men like Polus, Thrasymachus, and Euthydemus—to draw these consequences. Morality became mere convention, the rules of morals were considered contrary to nature, and natural right was consequently the right of the stronger. Independence of thought had thus degenerated into intellectual and moral anarchy, and individualism into pure selfishness.

However, despite the inability of the sophists to employ the instruments of reason towards a constructive philosophy, their criticism of knowledge and morality focused attention on the fallacies and weaknesses of hitherto accepted standards and beliefs. The great value of the sophistic movement was that it wakened thought and challenged philosophy, religion, custom, morals, and the institutions based on them, to justify themselves to reason. And this was the challenge that Socrates (also classed as a sophist though he did not teach for pay) took up, meeting the threat of materialism and skepticism to the intellectual and moral life of the nation by determining the conditions of intellectual knowledge and by laying a deep systematic foundation for ethics. C. W. D.

**SOPHOCLES** [sɒ'fəkliz] (c. 495-406 B.C.), Athenian dramatic poet, was born sometime in the period 497-494 B.C., the son of a wealthy manufacturer, Sophillus, who lived in the district of Colonus about a mile northwest of Athens. As a boy, Sophocles received an education which emphasized thorough training in music, dancing, and gymnastics. He was pre-eminent in all of these and was noted for his grace and handsome appearance. Tradition has it that after the Greek victory over the Persians at Salamis in 480, he was chosen leader of the chorus of boys selected to sing the victory song. While still in his twenties (468 B.C.), he won first prize in the tragic contests in competition against Aeschylus, and from then on throughout more than sixty years of productivity his literary career was one of exceptional success. During this period he was also elected by the people to a number of important political offices. In 440 he was chosen along with Pericles as one of the ten generals of the state *(strategoi)*, one of the highest offices in public life. This and similar honors came to him probably because of his popularity as a tragic poet and not because of any particular aptitude for political affairs. He was active, too, in religious offices and seems to have performed certain priestly functions connected with the cult of Asclepius. He was regarded by the people as a favorite of the gods and was accorded a number of religious honors. Sophocles was so fond of his fellow citizens and his city that although he was invited to the courts of many rulers, he stayed in Athens throughout his life. And after his death the Athenians appear to have worshipped him as a semidivine hero under the name Dexion and to have built him a shrine at which they sacrificed yearly.

Of Sophocles' private life it is known that he married a woman named Nicostrate and by her had a son, Iophon, who himself wrote tragedies. He also was reputed to have had a son Ariston by a certain Theoris of Sicyon. Three other sons are named by one ancient source but nothing else is known about them. Sophocles died in the fall of 406. His career coincided with the birth, maturity, and decay of the greatness of Athens and its empire. In the midst of one of the most eventful periods of human history, he seems to have led a tranquil life of prosperity, universally admired as a man and as an artist.

**Works.** Sophocles composed some one hundred and twenty dramas, of which the titles of one hundred and fourteen are known. Most of them were produced at public religious festivals at Athens in groups of four plays on unrelated themes, trilogies of tragedies plus single satyr-plays, in competition with similar groups by Aeschylus, Euripides, and other poets. Sophocles won over twenty first prizes, more than any other Greek dramatist, and was never awarded less than second prize. Early in the Christian era seven of his

plays were selected by scholars as specimens for school study and these are the only ones which have survived. We possess no tragedies dating from the first half of his literary career; those that are extant date between his fiftieth and ninetieth years. They are: *Antigone* (probably 442 or 441), *Philoctetes* (409), *Oedipus at Colonus* (402, the date of its posthumous presentation), and, of uncertain date, *Ajax, Oedipus Tyrannus, Trachiniae,* and *Electra.*

SOPHOCLES

COURTESY OF THE NEW YORK PUBLIC LIBRARY

**Technique.** Tragedy suffered no basic alterations of form in the hands of Sophocles. It remained essentially what it was with Aeschylus, a highly complex art form combining metrically phrased speech, music, dance, and intricately metered song. According to ancient testimony, however, certain innovations were made by Sophocles. The more important of these were: (1) The introduction of the third actor, a change leading to greater flexibility and liveliness of dialogue, to fuller delineation of character, and to greater complexity of plot, as well as to a reduction of the importance of the chorus; (2) the use in the standard tragic trilogy of three separate plays with unrelated themes instead of three based on one theme as in Aeschylus' *Oresteia;* (3) development in the use of painted scenery; and (4) the increase of the chorus from twelve to fifteen members.

Sophocles' greatness, however, consisted not in his inventions but in his gradual perfection of the form which he had inherited. At the height of his productive career he became an unparalleled craftsman, particularly in his construction of plot and portrayal of character. Working in the same restricted area of mythical tradition as his predecessors, he broadened the scope of tragedy by bringing it down from its supernatural heights to the level, not of common man to be sure, but of heroic man idealized. He did not neglect the great moral and religious problems handled by Aeschylus but he did not permit them to obscure the human interest of his stories. He made them the background against which the human characters moved. He enriched the legends with a variety of incidents and motives skillfully interwoven and secured verisimilitude by relegating what was implausible to the antecedents of the plot. The course of events in his plays was natural; scenes and events were joined with smoothness and ease, and he took especial pains in motivating the entrances and exits of the players. With all his striving for harmonious structure, Sophocles' principal object was representation of human nature in action. He desired to make his hearers concentrate their attention upon the ethical and moral meanings of certain situations and actions and upon the character of the human agents. Thus his characterizations lay midway between the sketches of Aeschylus, drawn with a few bold and decisive strokes, and the comparatively intricate psychological portraits of Euripides.

Sophocles made particularly effective use of dramatic irony, and "Sophoclean irony" has become proverbial. It was of two kinds, verbal irony and irony of situation or destiny. Verbal irony itself was of two types. In one type the speaker, foreseeing the doom that was to come to another, grimly rejoiced in the prospect, using ambiguous language understood by the audience but not by the victim. The dialogue between Electra and Aegisthus at the close of *Electra* is a good example. In the other type, either an observer of the action, ignorant of the true state of affairs, or the unknowing victim himself was the speaker of double-edged phrases open to an interpretation quite different from his intended meaning. *Oedipus Tyrannus* is a perfect example of this type as well as of irony of situation.

**Thought.** Combining Aeschylean elevation of thought with the psychological insight of Euripides, Sophocles stood as a mean between these two poets. His plays dealt with serious and universal problems, for many of which he proffered no sure solution. His main concern was with man, his position in the world, his potentialities for good and evil, and his relation to the gods. The leading characters of Sophoclean tragedy were human beings cast in the heroic mold and the plots were designed to reveal their personalities. Both ancient and modern critics have admired Sophocles as a superb painter of such human characters. His portraits, however, were more than mere artistic studies; they were searching examinations of human ideals, of human values, and of the meaning of a human life that was subject to strict control by the gods. These gods were figures of the popular religion who had come down essentially unchanged through literature and cult from the time of Homer. It has been said that Sophocles accepted these conventional deities without qualification and without question. This is an oversimplification. Certainly he did not analyze them or attempt to determine the nature of the divine; he had no new theology, he did not try to justify the ways of god to man, he was no zealous reformer or preacher. Yet his conception of the divine and its role in human affairs was clear and positive. For him the gods were omnipotent and omniscient figures, inscrutable to humans and working for mysterious ends which were often incomprehensible, yet deserving unquestioning reverence; their laws could not be transgressed with impunity. They assigned man his lot, which was his to bear; within the limits which they set upon his action he was a free and responsible agent possessing dignity and worth; outside of them, his actions became immoderate and likely to create the tragic situation. The essence of this Sophoclean view of life can be found most wonderfully expressed in two magnificent choral odes, one on the eternal divine laws in *Oedipus Tyrannus* (ll. 863-910), the other on the wonders of man in *Antigone* (ll. 332-367). In these and others of his plays it can be seen how, with expert stagecraft and supreme mastery of the poetic art, Sophocles blended perfect form with an exalted and comprehensive interpretation of life. This was his genius. The achievement has been rarely matched in literature. *See also* AJAX; ANTIGONE; ELECTRA; OEDIPUS AT COLONUS; OEDIPUS TYRANNUS; PHILOCTETES; TRACHINIAE. S. D. At.

**SOPHRON** [so'frŏn], Greek playwright of Syracuse of the fifth century B.C., the inventor of the ancient literary genre called the mime, a short, quasi-dramatic sketch exhibiting realistic scenes from daily life. Sophron probably took as

his models certain early, popular dramatic skits and elevated them into a literary form; although he himself wrote in prose, it was perhaps consciously rhythmical, and later literary mimes are in verse. Sophron's works, now lost, were greatly admired by Plato, who was said to have kept the mimes of Sophron under his pillow and used them as models for his early Socratic dialogues. Some idea of the nature of Sophron's works may be gained from later imitations and adaptations: the second and fifteenth idylls of Theocritus and the fourth mime of Herodas are said to have been derived from them. Dramatic mime, which was very popular in Rome and almost drove all other dramatic forms from the stage, was another offshoot of the early, subliterary dramatic skits of the Dorian Greeks, especially of the so-called Phlyax Comedy of Sicily and South Italy. *See also* HERODAS. C. T. M.

**SOPRANO** [sopra′no], a term in music for voices in the highest range, extending upward for about two octaves from about middle C. Sopranos include not only the higher female voices but also boy sopranos, with unchanged voices, and male sopranos, either *castrati* or falsetto singers. Female sopranos are commonly classed as lyric when they are straight singers of songs and ordinary choral music, dramatic when they are concerned with operatic roles requiring greater power and depth of tone, and coloratura when they are practiced in the florid arias of eighteenth- and nineteenth-century opera and oratorio. In four-part writing, either choral or otherwise, the highest part is called "soprano," and the term also designates the highest or next-highest members of the trombone, saxophone, or other instrumental families. In the saxophone, sarrusophone, and similar instrumental families developed during the nineteenth century, the very highest instrument, which is usually pitched in E-flat, a fourth higher than the B-flat soprano, is called "sopranino."

The term "mezzo soprano" is used to designate a female voice between soprano and alto in pitch. W. Li.

**SOPRON** (Ger., **ÖDENBURG**) [sho′pron ö′dənburχ], capital of the ancient *comitat de Sapron,* located 6 mi. west of the south end of Neusiedler Lake in northwestern Hungary. It is an Austro-German city around which the Hungarian boundary was placed after the 1921 plebiscite. Sopron is a market town serving a grain and grazing region in the foothills. The first established college of mining and forestry in Europe is located in Sopron. Raiding, the Franz Liszt birthplace, is near by. Pop. (off. est. 1948), 42,255. H. J. R.

**SOPWITH, THOMAS** (1803-1879), English mining engineer, was born in Newcastle-on-Tyne on Jan. 3, 1803. He was the son of a cabinet-maker, and when his education at private schools in Gateshead and Newcastle was completed he was apprenticed to his father. He proved apt at drawing and began to show considerable interest in surveying and mining. In 1822 he submitted plans and drawings for a new prison in Newcastle and two years later received his father's consent to leave the family business in order to take a position as assistant to a mining and land surveyor, whose partner he later became. His work was varied and diffuse, including church plans, mine studies, and road surveys. He frequently addressed technical societies and wrote numerous papers, of which the most important are *On the Construction and Use of Geological Models in Connection with Civil Engineering,* for which he received the Telford Medal in 1841; *The National Importance of Preserving Mining Records* in 1844; and *On the Practical Importance of Geology* in 1859. He was elected a Fellow of the Royal Society in 1845 and was also a member of the Meteorological Society, of which he was president from 1859 to 1861. Sopwith enjoyed travel and in 1857 published an account of one of the most extensive of his journeys: *Notes of a Visit to Egypt, via Paris, Nîmes, Marseilles and Toulon.* He was much concerned with the welfare of the miners whom he supervised, and during his twenty-six years as mine agent he introduced many reforms, both in sanitation and educational facilities. He died Jan. 16, 1879, in London. S. M. M.

**SORATA.** *See* ILLAMPÚ.

**SORBIAN** [sɔ′rbiən], also called Wendish, especially by the Germans, and Lusatian Serb, a Western Slavic dialect now spoken in the upper valley of the Spree, formerly belonging in part to Prussia and in part to Saxony; as late as the sixteenth century it occupied practically all of Lusatia. Sorbian is the only living remainder of that vast mass of Slavic population which once occupied the whole of Eastern Germany up to the Elbe and even beyond. It is divided into two geographically separated and widely different dialects, Upper Sorbian to the South and Lower Sorbian to the North; it is spoken by 70,000 to 120,000 persons. It is in some respects a very conservative language, preserving the dual and the Slavic imperfect and aorist. It shows some connections with Polish on one side, having the treatment *trot* of the *tort* groups where Czech has *trat,* and with Czech on the other, since the Sorbian accent is fixed on the first syllable. The oldest Sorbian literary text is a translation of the New Testament in Lower Sorbian (1548). Since the Romantic period, a national movement favored by the Czechs and Poles has developed among the Sorbs. G. B.

**SORBONNE.** *See* PARIS, UNIVERSITY OF.
**SORBOSE.** *See* SUGAR CHEMISTRY.

**SORDELLO** [sɔrdɛ′lo], a poem in six books by Robert Browning, written in four periods over seven years, and published in 1840. Its purpose was to show the "development of a soul," and its vehicle was the legendary career of Sordello, the troubadour poet of Dante's *Purgatorio.* Like *Paracelsus, Sordello* is concerned with love, aspiration, defeat, triumph, and death, and owes more to Shelley and young Browning than to history. The poem is not carefully finished, and remains a potpourri of romance, psychology, and philosophy, with magnificent poetic interludes. Incomprehensible to reviewers, *Sordello* blighted Browning's reputation for 25 years. W. C. De V.

**SOREL, ALBERT** [sɔ′rɛ′l] (1842-1906), French historian and public official, was born in Honfleur, Normandy, Aug. 13, 1842. His masterpiece, *L'Europe et la révolution française* (8 vols., 1885-1904), corrected the earlier studies of Heinrich von Sybel and has remained a standard work on the international aspects of the French Revolution. Sorel interpreted the wars of the Revolution and Napoleon as a continuation of Louis XIV's expansion in quest of natural frontiers. In addition to his career as a historian, Sorel taught diplomatic history at the École Libre des Sciences Politiques and served in the French foreign office from 1866 to 1875. In 1875 Sorel became general secretary to the president of the senate, which gave him both income and leisure to carry on his historical research and writing. He was elected to the French Academy in 1894, and the Prix Osiris of 100,000 francs was awarded to him shortly before his death in Paris, June 29, 1906. R. M. Br.

**SOREL, GEORGES** (1847-1922), French engineer and social philosopher, was born in Cherbourg on Nov. 2, 1847. He was educated at the École Polytechnique and for twenty-five years was an engineer with the Department of Bridges and Highways. Becoming interested in revolutionary socialism, however, he resigned in 1872 and devoted himself to study and writing. Influenced by Proudhon, Marx, and Nietzsche, he helped to launch the syndicalist movement in France, acting as theoretician for the movement. Essentially a moralist rather than an economist or philosopher, Sorel was an anti-intellectual, anti-parliamentarian pessimist, whose revolutionary fervor was more authoritarian than it was humanitarian or consistent. He attack the faith in progress characteristic of the democratic optimism of the nineteenth century and posited the "myth of a general strike" and the "primacy of violence" as the rather cynical means toward revolutionary action. Largely on the basis of *Reflexions sur la violence* (1908), his best-known book, he has been credited with having had an influence on Mussolini and the rise of fascism, but his ideas lacked sufficient cohesiveness to have been of much importance. He died in Boulogne-sur-Seine on Aug. 30, 1922. C. W. D.

**SOREL** [sɔ′rɛ′l], a port city and the county town of Richelieu Co., Quebec, Canada, situated at the confluence of the Richelieu and St. Lawrence rivers, 43 mi. northeast of Montreal. It is located on Highways 3 and 21 and is served by the Canadian National Railways. Named for a Captain de Saurel who commanded the first French fort built on the site in 1665, it was incorporated as a city in 1889. An important port with extensive wharves and grain elevators, it is also a manufacturing center with shipyards, steel works, armament plants, a sawmill, and clothing factories. Pop. 1951, 14,961. D. F. P.

**SORGHUM** [sɔ′rgəm], *Sorghum vulgare,* a member of the grass family having many varieties of economic importance. It is a tall, strong, erect annual, much like Indian corn. Although believed to be a native of Africa, its origin has never been determined, but since very ancient times it has been a staple food for enormous populations in warm regions such as China and Egypt. In the many centuries of cultivation numerous valuable varieties have been developed which comprise four classes: (1) the saccharin sorghum with sweet, juicy pith, grown for fodder and syrup-making; (2) the grain sorghums grown for their starchy seeds, used for food and to some extent for fodder; (3) broomcorn sorghums whose long stiff rays of the flowering panicle are used for brooms; (4) the grass sorghums which include Sudan grass and are usually associated with the grasses. Climate often determines which of these classes are grown. From Kentucky and Missouri southward, sugar sorghum, var. *saccharatum,* is grown for syrup. Sorgo is another syrup variety. More than 40 types of grain sorghums are in cultivation in the United States, grown chiefly as forage and food for stock and poultry. They include chicken corn, var. *drummondii,* developed in Guinea; durra, var. *durra,* coming from the Nile valley and including forms known as yellow milo, Jerusalem corn, and Egyptian rice-corn; feterita, var. *caudatum,* of Central Africa, with several other varieties, both standard and dwarf, grown in Texas; milo and shallu, var. *roxburghii,* of India and Africa. *See also* Broom Corn. C. K. H.

**SORIA** [so′ryɑ], the province and the capital city of that province, in northeastern Old Castile, in north central Spain.

**The City.** The smallest of the Spanish provincial capitals, Soria is situated south of the Sierra Cebollera, on the upper Duero River, about 115 mi. northeast of Madrid. In the past Soria was important for its control over one of the principal routes from Aragon to Old Castile. This position was injured by the building of railways that passed it by so that Soria lies in an economic backwater in a generally backward region. Its chief function is as a local administrative and educational center and as a market place. Its industries are varied but small. Soria is on branch railway lines and is served by several regional highways. Despite its smallness, Soria is of considerable interest for its old buildings and monuments, its picturesque and narrow streets, as well as its *plazas* and *paseos.* The principal edifices include a number of churches, such as those of Santo Domingo and San Pedro (collegiate). The outward aspect of Soria has not changed markedly since late medieval times, and sections of the thirteenth-century walls remain.

Three miles north of the city, at the confluence of the Tera and the Duero rivers, lie the ruins of Numantia, an ancient town of Iberian origin that long resisted Roman conquest and later acquired importance under the Roman Empire. During the rise of Castile in the twelfth and thirteenth centuries, Soria was rebuilt and fortified. It played a minor role in the intra-peninsular wars and family quarrels that have marked Spanish history. Soria was the seat of a department during the Napoleonic era. Under the Restoration it continued as capital of a province, of which the boundaries were fixed in 1833. Pop. 1947, 15,425.

**The Province.** The province, which has an area of 3,977 sq. mi., corresponds roughly to the upper end of the Duero basin, though two small sections extend across the divide into the upper Ebro watershed. The terrain around the northern, eastern, and southern edges is generally mountainous, being bounded by the Sierra Cebollera, the Sierra del Moncayo, and the Sierra de Guadarrama, respectively. Elsewhere is part of the central plateau, or *meseta.* Nearly three fourths of the area lies more than 4,000 ft. above sea level. The climate is continental with long, cold winters and hot summers. Precipitation is scanty, ranging in the vicinity of 20 to 25 in. and usually falling only a few days a year. The population has been virtually stationary since the end of the nineteenth century because of heavy emigration to New Castile and overseas, primarily to Argentina. Soria is the most sparsely populated province in Spain, with a population of about 40 per sq. mi. The economy is essentially agricultural and pastoral, and methods are primitive. There are a few mineral deposits, but because of the lack of transportation these have been exploited only in small part. Pop. (off. est. 1947), 162,218. R. G. W.

**SORITES.** *See* Logic.

**SOROLLA Y BASTIDA, JOAQUIN** [soro′lyɑ i basti′-thɑ] (1863-1923), Spanish painter and illustrator, was born in Valencia, Feb. 27, 1863. He entered the Academy in Valencia at the age of fifteen and in 1884 won second prize at the Madrid Exposition. Next year he went to Rome on a scholarship, later visiting Paris, where he admired the works of Jules Bastien-Lepage and Adolph Menzel. He also became familiar with the work of the French Impressionists. Sorolla attained public recognition in the 1890's, and from then until his death he was internationally known.

His great output of painting embraces the life of the people of Spain, landscapes, seascapes, and portraits. He painted steadily throughout his career, and, using the direct, informal technique of the Impressionists, he could paint

rapidly. He was interested principally in recording the instantaneous effect of figures or objects as they appeared in strong sunlight and shadow. Many of his characteristic works of children romping on the beach are in the collections

JOAQUIN SOROLLA Y BASTIDA

COURTESY OF THE NEW YORK PUBLIC LIBRARY

of major museums. In 1919 he became professor of painting at the Academy in Madrid. Sorolla died in Madrid, Aug. 11, 1923. G. D.

**SORORITY.** *See* FRATERNITY.

**SORREL, HETTY,** a character in George Eliot's *Adam Bede* (1859), who kills her newborn, illegitimate child. Her death-sentence is commuted to transportation. G. G. F.

**SORREL,** also sheep sorrel or sour dock, a small herb, *Rumex acetosella,* of the buckwheat family naturalized in North America from Europe and Asia. It is a perennial with running rootstocks, and acid-tasting, halberd-shaped leaves. The tiny flowers, clustered on branching stalks, are yellowish or reddish. Its vigorous creeping habit makes it a troublesome weed in lawns and gardens. J. C. Wis.

**SORREL TREE,** a medium-sized tree, *Oxydendrum arboreum,* of the heath family, also called sour-wood. It is found from Pennsylvania and Indiana to Florida and Louisiana. The sorrel tree has a central trunk and slender branches, and sprays of small urn-shaped white flowers in clusters in summer. It is planted for the brilliant fall color of the sour, oblong leaves. J. C. Wis.

**SORRENTO** [sorrɛ′nto], a resort town on the southern shore of the Bay of Naples, located in Napoli Province, southern Italy, about 25 mi. west of Salerno. The town, strung out on terraces rising to 200 ft. above the sea, lies on the coast road between Naples and Amalfi, and is served by rail, steamer, and busses. Its picturesque site and mild climate have made Sorrento popular with sojourners. The remains of the Roman and medieval eras are fragmentary and of no great interest. Sorrento early became an episcopal seat, and during the Dark Ages appears to have been largely independent under its own dukes, and often in conflict with Amalfi and the Saracens. In 1137, it fell to the Normans and thereafter shared the political fortunes of Naples and its kingdom. Pop. (est.), 9,898. R. G. W.

**SORROWS OF YOUNG WERTHER, THE,** a sentimental and psychological novel in letter form, written by Johann Wolfgang von Goethe and published in 1774, with the title *Die Leiden des jungen Werthers.* The work established its author's international fame. It contains in its first part a more or less biographical account of Goethe's unhappy infatuation for Charlotte ("Lotte") Buff, fiancée of his friend G. C. Kestner, during the poet's otherwise happy summer of 1772 at Wetzlar, where he served his jurisdictional apprenticeship at the supreme court of the Holy Roman Empire. Its second part is based on the unfortunate experiences and fate of Karl Wilhelm Jerusalem, secretary of the Brunswick ambassador, who, snubbed by the aristocratic society of the Court, reprimanded by his superiors, and in love with the wife of a colleague, committed suicide in October 1772. The fusion and crystallization of these materials and characters, however, was effected through a painful incident that Goethe experienced in February 1774 at the house of the jealous husband of Maximiliane Brentano.

The sensational success of the novel cannot be attributed exclusively to the consummate art with which Goethe tells an apparently simple love story in epistolary form. Since the publication of the *Letters of a Portuguese Nun* (1669), the epistolary novel had slowly matured in such works as the writings of Samuel Richardson and in Jean Jacques Rousseau's *Julie; ou, la Nouvelle Héloise,* and *Werther* is one of the finest examples of the form. The letters of Werther are ostensibly written to a friend, whose sympathetic and warning voice might well be the reader's. But the content of the novel is more than the fate of Werther, who assumes that the outside world corresponds to the picture of it that he bears in his own heart. It is the creed of a whole generation protesting against the facile and optimistic rationalism of their elders who had viewed the marvelous abundance of nature as a system of abstract laws, its mysterious creator as a clockmaker, its life adventures as a set of moral precepts, and its devious paths of frustration and attainment as a calculable road to happiness to be reached through reasonable behavior. *Werther* proclaimed, in opposition to this view, the rights of the heart. The enthusiastic response of its readers, the translations of the novel into most European languages, its sequels, imitations, and dramatizations, and the *Wertherfieber* which was its unfortunate aftermath testify to Goethe's success in directing into a single channel the manifold currents of sentimentalism. E. F.

**SORSOGON** [sɔ′rsogɔ′n], a Philippine municipality and port, the capital of Sorsogon Province, located on Sorsogon Bay near the southeast tip of Luzon. At the mouth of the Sampaloc River, which flows into the head of the bay, the town lies on level ground but is surrounded by rolling, fertile terrain of volcanic origin. The shore line in front of the town rises abruptly, and fishing houses have been built over the bay. Abaca is the chief product, but copra is also exported and fish are sold to other parts of the Philippines. Sweet potatoes and cassava are major food crops in the province. The 16-mile-long bay affords excellent protection, but near its head the water is shallow, making it necessary for most vessels to anchor two or three miles from the port and transfer their cargo into smaller craft. In 1840 a severe earthquake killed seventeen persons, injured many more, destroyed many buildings, and caused the land to drop from four to five feet below its former level. Pop. 1948 (town) 9,971; (municipality) 26,004. A. Cu.

**SOSNOWIEC** [sɔsnɔ′vyɛts], a city in the Polish province of Kielce, located 35 mi. northwest of Kraków and about 160 mi. southwest of Warsaw in the Silesian coal area. It is an important railway junction and before World War

II was the second largest industrial city of Poland and the center of Polish coal mining. The city's industries include textile factories, rolling mills, electric power stations, and steel works. Pop. 1946, 77,834. L. M. A.

**SOTHERN, EDWARD HUGH** [sʌ′thərn] (1859-1933), American actor, son of the Anglo-American actor Edward Askew Sothern, was born in New Orleans, La., on Dec. 6, 1859. He was married twice: to Virginia Harned in 1896,

EDWARD HUGH SOTHERN

BROWN BROTHERS

and to Julia Marlowe in 1911. He toured England in 1882 and 1883 and joined the company of John McCullough in the latter year; from then until 1899 he was leading man in Daniel Frohman's Lyceum Theatre company in New York. Sothern had enormous success in romantic comedies on the order of *Richard Lovelace, If I Were King,* and *The Prisoner of Zenda,* and in Gerhart Hauptmann's mystical play, *The Sunken Bell.* He first played Hamlet in 1900. In 1904 he made his first appearance opposite Julia Marlowe in *Romeo and Juliet.* Thereafter their notable partnership in Shakespearean repertory made them foremost exponents of the Classic drama of their day. In 1916 he presented a gala revival of *If I Were King* to raise money for the British Red Cross. After Miss Marlowe's permanent retirement from the theatre in 1924, Sothern appeared under the management of David Belasco in two plays, *Accused* and *Hidden,* in 1925 and 1926, after which he left the stage to embark on a lecture tour. He said at the time, "I have not left the stage; the stage has left me." Sothern's autobiography, *The Melancholy Tale of Me,* was published in 1916. He died Oct. 28, 1933, in New York City. E. C. Ro.

**SOTHO.** *See* African Peoples.

**SOTOL** [so′tol; soto′l], a common name for *Dasylirion,* a genus of treelike desert plants of the lily family. The plants, to 6 ft. in height, bear linear, usually spiny, marginal leaves, and whitish lilylike flowers in dense panicled racemes. The leaves are used for thatching or baskets, and the fiber is made into cordage; the heads are edible, and the sap is sometimes made into an alcoholic beverage. All species are native to Texas, Arizona, and Mexico. L. de F.

**SOUARI NUT** [suɑ′ri], also called suarrow, or sawarra, *Caryocar nuciferum,* a timber tree growing to 100 ft. in height, native to Surinam. It bears, within its huge woody fruit, a number of extremely hard-shelled, kidney-shaped, warty, nutlike seeds, 2 in. or more in length. In texture and flavor, the edible flesh resembles a Brazil nut but has a tinge of almond flavor. Though the flavor of this nut is one of the finest known, the trees do not occur in sufficient quantities to make shipment profitable. In their native land, the trees are used for ship timber. C. H. Wo.

**SOUEIDA** or **ES SUWEIDA** [swe′da′, æs sʊwai′də], a city in the southwestern part of Syria, located about 58 mi. southeast of Damascus and 60 mi. northeast of Jerusalem. It is a railroad terminus, built on the site of an ancient Roman town. Soueida is situated on the edge of the rugged plateau which includes the 5,900-ft. peak of Jebel Druze. The lava plateau has been eroded into sharp peaks and steep valleys and is an inaccessible, semidesert region. To the north of Soueida lies the flat, fertile, wheat-producing area, immediately southeast of former Druse territory of Jebel ed Druz. The climate of Soueida is a modified Mediterranean type with short, cool winters and long, hot, dry summers. The average annual precipitation is about 15 in. a year, and almost all the rain falls during the winter months. The vegetation is grass, thorn bushes, and some pine trees. Agriculture and grazing are the two most important activities, wheat, millet and some vegetables being the chief products, and goats, sheep, and camels the animals pastured. Soueida is a famous center of the Druses, survivors of a Mohammedan sect founded in the tenth century. This small but fierce group took refuge in remote and inaccessible areas, winning from the French a semi-independent state within the French Mandate, with Soueida as their principal city. The Druses fought all French attempts to control the region and assisted Damascus in its attempted revolts in 1920 and 1926. Soueida was incorporated in the Arabic Republic of Syria on Jan. 12, 1942. Pop. 1953, 12,153. J. E. F.

**SOULT, NICOLAS JEAN DE DIEU (DUC DE DALMATIE)** [su′lt] (1769-1851), French marshal, was born at Saint-Amans-la-Bastide in the south of France on Mar. 29, 1769. At the age of sixteen he entered the French army, becoming a second lieutenant in 1791 and a captain two years later. He participated in the war against the First Coalition, and was made a general in 1794, but he showed his great strategical skill particularly in the Swiss and Italian campaigns (1799 and 1800) under André Masséna. Nominated marshal the day after the proclamation of Napoleon I as Emperor (1804), Soult took a decisive part in the Battle of Austerlitz (1805) and in the war against Prussia and Russia (1806-1807). Made Duke of Dalmatia in 1807, he was sent to Spain at the end of that year, where he was the leading French general until the beginning of 1813. After having participated in the initial battles of the Wars of Liberation, in the summer he was again dispatched to the south of France in order to stem the onslaught of the Duke of Wellington. During the First Restoration, Soult was made minister of war, but during the Hundred Days he accepted the post of chief of staff to Napoleon. From 1816 to 1819 Soult was exiled from France, but was called back by the Crown, which renewed his marshalship the following year and his peerage in 1827. Just as his political convictions had not hindered Soult from serving the Republic as well as the Empire and the Bourbons, he accepted under Louis Philippe the post of war minister during 1834. He was minister for foreign affairs in 1839, head of the government during 1832-1834, 1839-1840, and again in 1840-1847, foreign minister in 1839-1840, and ambassador extraordinary for the coronation

of Queen Victoria in 1838. Soult died at his castle of Soultberg, near his birthplace, on Nov. 26, 1851. W. Fr.

**SOUND,** the vibrational motion of matter displaced from equilibrium. In a continuous material, the displacement of one particle from its rest position causes a displacement of neighboring particles by elastic forces, and the disturbance spreads through the material in the form of a sound wave.

Sound may produce the sensation of hearing when vibrations occur in air more frequently than 15 or 20 times a second and less frequently than about 20,000 times a second. The frequency of a vibration is measured in cycles per second (c.p.s.) and is given by the number of times per second a vibrating object moves through its equilibrium position in the same direction. Thus, a sound is audible when its frequency lies between about 15 and 20,000 c.p.s. Frequencies lower than 15 c.p.s. are called subsonic, and frequencies greater than 20,000 c.p.s. are called ultrasonic. The word supersonic was sometimes used to denote ultrasonic, but now applies to a speed greater than the speed of sound in air. Normal human ears cannot hear sounds with ultrasonic frequencies, although some people and certain animals, e.g., dogs and bats, can hear frequencies well above the average limit of human audibility. Sounds with subsonic frequencies cannot be heard but may be experienced as a sense of bodily vibration or as pressure. Many subsonic vibrations are accompanied by audible sounds, but the sensation of hearing can usually be distinguished quite readily from the kinesthetic sensation caused by low-frequency vibration.

Considered as a physical phenomenon, sound includes mechanical vibrations with a much wider range of frequencies than that determined by the limits of audibility. The subjects of seismology and structural mechanics are concerned with frequencies of about one cycle per second or less, whereas molecular vibrations, considered in quantum mechanics, have frequencies of the order of 1 billion cycles per second or more. Acoustics, the science of sound, deals with vibrational motion in the intermediate frequency range between 1 c.p.s. and $10^9$ c.p.s.

The distinction between sound and vibration is largely a matter of viewpoint, since both words describe the same physical phenomenon. When attention is fixed on an individual object or particle, a repeated to-and-fro motion is called periodic motion or vibration. When the periodic motion of an individual particle is due to pressure exerted by neighboring particles of the same material or a surrounding medium, the related motions of the entire group of particles are called sound. These form a wave which progresses through the material with a definite speed in approximately the same way that a wave of disturbance travels through a closely spaced row of dominoes standing on end when one is tipped over.

## SIMPLE VIBRATING SYSTEMS

**Free Vibrations of a Mass and a Spring.** The simplest vibrating system contains two components, a mass and a spring, each associated with a characteristic type of force. The force required to extend or compress a spring unit distance is called the stiffness, $k$, of the spring. If one end of a spring is fixed, a displacement, $x$, of the other end from its equilibrium position is accomplished by a force, $F_k$, given by Hooke's law: $F_k = -kx$.

The negative sign indicates that the force exerted by the spring opposes the displacement. This restoring force acts to return the displaced end of the spring to its equilibrium position whether the spring is compressed or extended. If the displacement is too large, the spring can be permanently distorted, and Hooke's law will not apply. But in most systems related to sound, the vibrations are small and the restoring force is proportional to the displacement. When this is true, a spring possesses a linear, or Hooke's law, stiffness.

*Simple Harmonic Motion.* A fundamental type of vibration known as simple harmonic motion occurs when the force of a spring acts directly on a mass. The force between the spring and the mass obeys both Hooke's law and Newton's law, so that the equation of motion is $F = ma = -kx$; and the acceleration, $a = -\frac{k}{m}x$, is proportional to the displacement but in the opposite direction.

An important feature of the free vibrations of linear spring-mass systems is that the natural frequency does not depend on the amplitude but only on the ratio of stiffness to mass.

*Damped Systems.* The vibrational motion of a spring-mass system has been identified as simple harmonic motion, in which the amplitude does not change with time. It is common observation, however, that free vibrations gradually die away. This behavior, called decay, is due to the presence of a third component, resistance, in the system. A resistance is characterized by a force which opposes the motion and is (to a first approximation) proportional to the velocity; a system which contains such forces is called a damped or dissipative system.

Sound and vibration involve two principal types of resistance, namely, friction and radiation. Frictional resistance

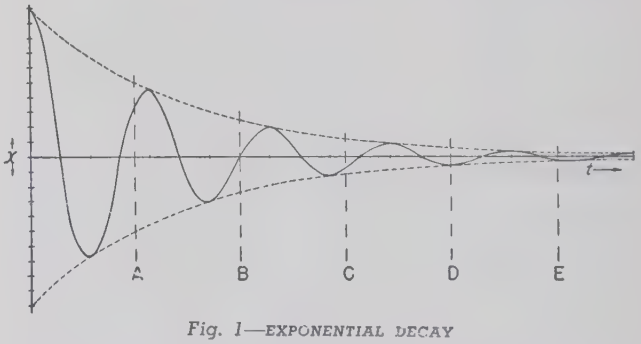


*Fig. 1—EXPONENTIAL DECAY*

*Reduction in amplitude of vibration as compared with original value of amplitude: (A) ½; (B) ¼; (C) ⅛; (D) 1/16; and (E) 1/32 (x) Displacement; (t) Time*

accompanies the flow of a viscous liquid or gas around an obstacle. Radiation resistance occurs when a vibrating object produces sound waves which carry energy away. Both types of resistance exert a force, $F_r$, on a moving object described by: $F_r = -rv$, where $r$ is a constant called the *resistance.*

When resistance is added to a spring-mass system, the equation of motion must be modified to read:

$$a = -\frac{k}{m}x - \frac{r}{m}v.$$

It is characteristic of the free vibrations of a damped system that the displacement amplitude decreases by the same fraction during all equal intervals of time. This behavior, known as exponential decay, is illustrated in Fig. 1. The damping of an exponential decay is described by a decay constant, $k = r/2m$, or by the reciprocal ratio, $2m/r$, which is called the modulus of decay and is the time interval required for the amplitude to decrease to $1/e (= 0.368\ldots)$ of its value at the beginning of the interval. The addition of resistance to a spring-mass system causes a small reduction

in the natural frequency, but for the resistances encountered in acoustics this effect is so small that it is usually ignored.

**Forced Vibrations of a Damped System.** *Sinusoidal Force.* Under the influence of an applied periodic force, a damped simple system undergoes forced vibration. The simplest type of an external periodic force is one that varies sinusoidally with time: $F=F_0 \cos \omega t$, where $F_0$ is the force amplitude and $\omega$ is the driving (angular) frequency. Since $\omega$ is a property of the external driving force, it may take on any value whatever, as distinguished from the natural frequency, $\omega_n=2\pi\nu_n$, which has a particular value determined by the constants of the system. The special case in which the driving frequency has the same value as the natural frequency is called resonance.

When a sinusoidal driving force is first applied to a system at rest, the initial motion, called the transient, is very complicated. But if the driving force continues with a steady frequency and amplitude, the vibration settles down to a steady state simple harmonic motion that continues as long as the driving force continues unchanged. The frequency of the steady-state vibration of a linear system is always the same as the frequency of the applied force, but the amplitude of the forced motion depends on the frequency.

*Impedance.* The responsiveness of a system in forced vibrational motion is described by the impedance of the system. A system with high impedance is hard to move and requires a large force amplitude to produce a specified amplitude of vibration, whereas a system with low impedance moves easily. The impedance, $z$, is defined as the force divided by the velocity, and its magnitude is the force amplitude required to produce a velocity amplitude of one centimeter per second. The impedance of a system generally varies with frequency.

When a force, $F$, is applied to an element of pure resistance, the resulting velocity is determined by a balance between the applied force and the resistive force, $F+F_r=0$. Since the resistive force is $F_r=-rv$, the ratio of applied force to velocity is: $z_r=F/v=r$; therefore, the impedance of a resistive element is independent of frequency and is equal to the resistance.

In a spring, an applied force, $F$, causes a displacement rather than a velocity: $F=kx$. But in simple harmonic motion the velocity is 90 deg. ahead of the displacement in phase and the velocity amplitude is larger than the displacement amplitude by a factor of $\omega$. This statement can be written: $x=v/\omega/\underline{-90^\circ}$; so that the impedance of a stiffness is $z_k=F/v=k/\omega/\underline{-90^\circ}$. It is clear that impedance is a vector quantity, since both its magnitude and phase angle must be specified. In this case the angle $/\underline{-90^\circ}$ indicates that the force, which has the same phase as the displacement, is 90 deg. behind the velocity in phase.

In a mass, an applied force causes an acceleration, $a=F/m$. In simple harmonic motion, the acceleration is 90 deg. ahead of the velocity in phase and the acceleration amplitude is $\omega$ times the velocity amplitude, so that: $a=\omega v/\underline{+90^\circ}$; therefore the impedance of a mass is: $z_m=F/v=\omega m/\underline{+90^\circ}$.

When a spring, a mass, and a resistance are combined into a simple system, the impedances of the three elements also combine; but because of the various phase angles, the impedances combine as vectors. At any frequency, the vector sum of the components of impedance gives the amplitude of the force required to produce unit velocity amplitude and the phase difference between the applied force and the velocity. Resonance occurs when the impedance of the spring just balances the impedance of the mass: $\omega m=k/\omega$, or $\omega=\sqrt{k/m}=\omega_n$.

At low frequencies, the impedance of the spring, $k/\omega$, is much larger than that of the mass or the resistance; at these frequencies, the motion is stiffness-controlled and the applied force is very nearly in phase with the displacement. Near resonance, the impedances of the mass and the stiffness are nearly equal, but they have opposite phase angles and hence cancel each other. The major contribution to the vector sum comes from the impedance of the resistance; such motion is resistance-controlled, and the force is approximately in phase with the velocity. At high frequencies, the major contribution to the total impedance comes from the mass impedance, $\omega m$, so the motion is mass-controlled and the force is very nearly in phase with the acceleration.

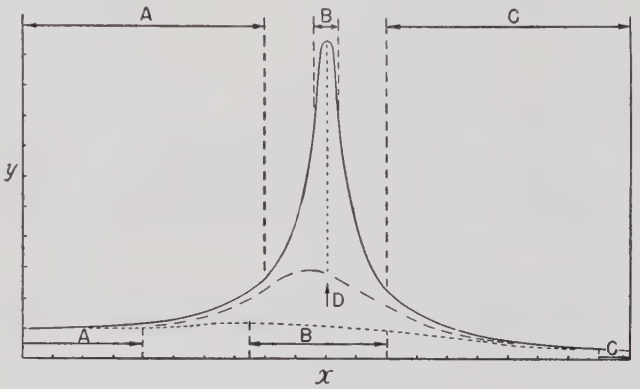

*Fig. 2—DISPLACEMENT AMPLITUDE OF A FORCED VIBRATION AT VARIOUS FREQUENCIES*

*(A) Stiffness-controlled; (B) Resistance-controlled; (C) Mass-controlled; (D) Resonance*
*(x) Displacement; (y) Frequency of applied force*

Because of the large impedance of a stiffness-controlled or a mass-controlled system, the displacement amplitude is low at frequencies well above or below the resonant frequency. In the vibrating systems of interest in acoustics, the resistance is usually much smaller than the impedances of the mass or the stiffness. Consequently, there is a low impedance in the resistance-controlled region, and the displacement amplitude passes through a maximum at resonance. The value of the displacement amplitude at various frequencies is shown in Fig. 2 for a simple system driven with a constant force amplitude. In this figure, the solid curve shows the behavior of a system with a small resistance, and the dotted curves show the behavior of systems with larger resistances.

*Complex Wave Forms.* Thus far, the discussion of forced motion has been limited to the case of a driving force which varies sinusoidally with time. It frequently happens, however, that the wave shape of the applied periodic force is not sinusoidal. Such cases are treated by considering the complex shape of the curve of force versus time as the sum of a number of sinusoidal forces with various frequencies and amplitudes acting simultaneously.

After a complex wave form has been analyzed into sinusoidal components by the techniques of Fourier analysis, the displacement due to each sinusoidal component can be obtained by evaluating the impedance at the appropriate frequency. The wave shape of the total displacement is then the sum of the component displacements at each of the frequencies in the harmonic series. These methods of analysis

and synthesis of complex wave forms are of great importance in the study of vibration and sound.

**Coupled Systems.** The previous sections considered the free and forced vibration of the simplest mechanical system, containing only a simple element of mass, of stiffness, and of resistance. This simple system can frequently be used to represent the gross behavior of a practical vibrating system such as a loudspeaker; the mass of the coil is acted on by the stiffness of the diaphragm and the motion is damped by the resistance of the sound radiated. Closer examination of the actual vibrating system, however, usually shows that more than one mass and more than one spring are involved. In a loudspeaker (*see* Fig. 3), each of the corrugated rings in the diaphragm acts as an element of stiffness, and the areas between the rings contribute mass and resistance.

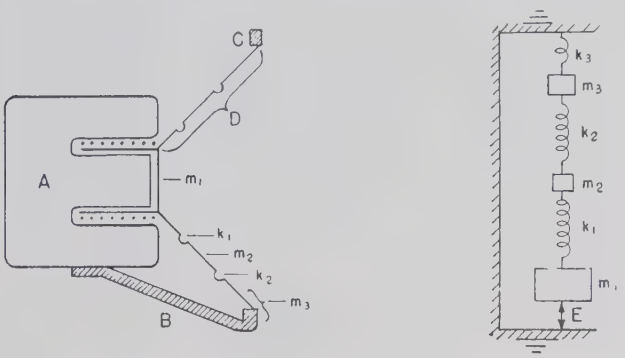

*Fig. 3—DYNAMIC LOUDSPEAKER (LEFT), AND EQUIVALENT COUPLED SYSTEM (RIGHT); (RADIATION RESISTANCE NEGLECTED)*

*(A) Magnet, large mass; (B) Bracket supporting the ring, stiffness $k_3$; (C) Ring; (D) Corrugated paper diaphragm; (E) Driving force applied between coil, $m_1$, and the large mass of the magnet, A; ($m_1$) Coil; ($m_2$ and $m_3$) Masses; ($k_1$ and $k_2$) Stiffness*

A single system that involves two or more masses interconnected by springs is called a coupled system. A characteristic of coupled systems is that the displacement of any single mass from its equilibrium position causes forces to act on the other masses of the system, as can be seen in the simple coupled system shown in Fig. 4. When either mass is displaced, the coupling stiffness, $k_c$, exerts a force on the other mass.

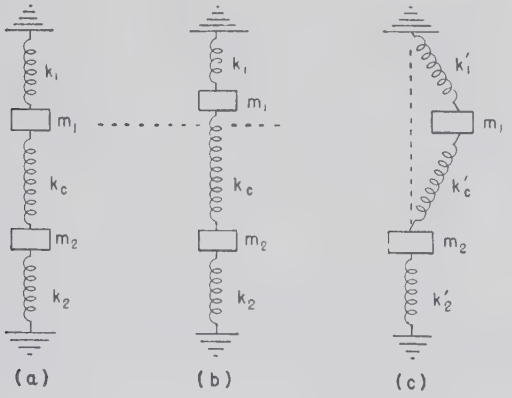

*Fig. 4—SIMPLE COUPLED SYSTEM*

*(a) System in equilibrium*
*(b) Upper mass displaced upward (longitudinally); force must be exerted on lower mass to keep it in equilibrium position*
*(c) Upper mass displaced sideward (transversely); force must be exerted on lower mass to keep it in equilibrium position. (The prime marks indicate that different values of the stiffnesses apply to tranverse displacements.)*

The behavior of a coupled system is most easily described in terms of the properties of the component simple systems. In Fig. 4, when the mass $m_2$ is clamped so that it cannot move, $m_1$ behaves like a simple system with a natural frequency at: $\omega_1 = \sqrt{\frac{k_1 + k_c}{m_1}}$. Likewise, when $m_2$ is clamped, $m_1$ behaves as a simple system with a natural frequency: $\omega_2 = \sqrt{\frac{k_2 + k_c}{m_2}}$.

When both masses are free to move, the system has two resonant frequencies instead of one. However, the coupling between the two simple systems causes the two resonant frequencies to lie farther apart than the two clamped frequencies. Even when the natural frequencies of the clamped simple systems have the same value, the two resonances of the coupled system are separated; one lies above and one below the common natural frequency.

The amounts by which the resonant frequencies are shifted depend on the degree of coupling. For very weak coupling, the resonances are shifted only a small amount. For a very strong coupling, one resonance of the coupled system occurs at a very high frequency, whereas the other resonance approaches the value obtained by combining the two masses into a single rigid body. The displacement amplitudes of the masses of a driven coupled system are shown in Figs. 5*a* and 5*b*, as a function of the frequency of the applied force.

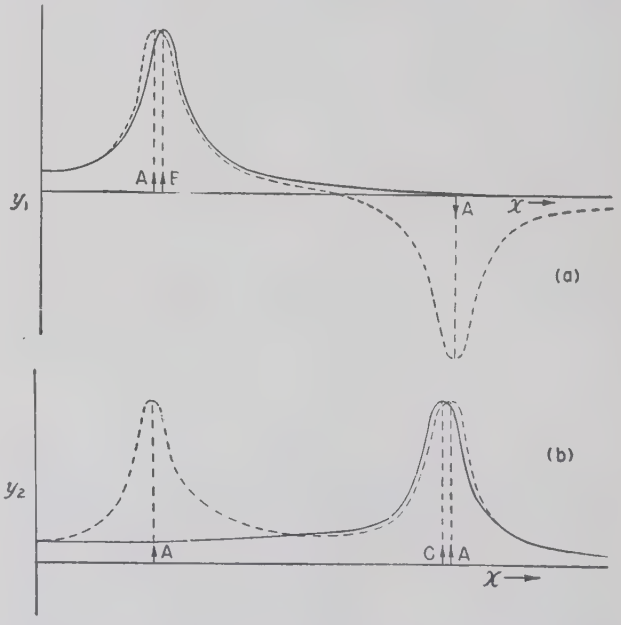

*Fig. 5—Displacement amplitudes of two masses in a coupled system; solid curves show displacement of one mass when other mass is clamped, while broken curves show displacement when both masses are free. (A) Resonance of coupled system; (B) Clamped natural frequency of $m_1$; (C) Clamped natural frequency of $m_2$. (x) Driving frequency; ($y_1$) Displacement amplitude of $m_1$; ($y_2$) Displacement amplitude of $m_2$.*

*Normal Modes of Vibration.* The character of the displacements is not the same at the two resonances. In the neighborhood of the low-frequency resonance, the two masses have the same phase, whereas in the neighborhood of the high-frequency resonance, the masses are always on

opposite sides of their equilibrium position and hence differ by 180 deg. in phase. The ratio of the amplitude of $m_1$ to the amplitude of $m_2$ depends in a complicated way on the values of the masses and stiffnesses involved. The types of displacement patterns for two equal masses in a coupled system are illustrated in Fig. 6. These same two patterns

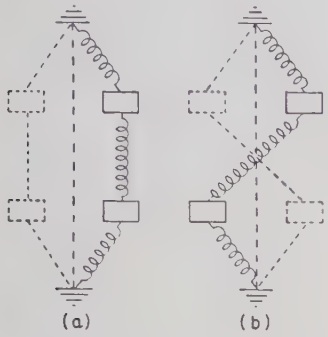

*Fig. 6—Normal modes of vibration of two equal masses: (a) Low-frequency resonance; (b) High-frequency resonance.*

of displacement are also associated with the free vibrations of the coupled system. If the masses are displaced initially into the pattern shown in Fig. 6b, both masses vibrate freely with simple harmonic motion at the lower resonant frequency. If the initial displacements follow the pattern of Fig. 6b, both masses vibrate with simple harmonic motion at the higher frequency. The patterns of the relative positions of the masses at the resonant frequencies are called the normal modes of vibration of the system, and in general each normal mode has a different natural frequency. The number of normal modes of a complex system is equal to the number of simple oscillators coupled together.

*Arbitrary Displacement.* If the initial conditions of a freely vibrating coupled system correspond to one of the normal modes, all masses move with simple harmonic motion at the natural frequency of that normal mode. If, however, the initial conditions do not correspond to one of the normal modes, the masses carry out a complicated motion that is not generally periodic and hence cannot be said to have a frequency. This motion consists of a combination of several simple harmonic motions with different frequencies and different amplitudes. By adding together the displacement patterns of all the normal modes of a system, each with an appropriate amplitude, it is possible to obtain any arbitrary initial displacement pattern. The analysis of an arbitrary displacement pattern into normal mode components is illustrated in Fig. 7. The possibility of constructing an arbitrary displacement pattern by adding together the patterns of the normal modes is a fundamental property of the normal modes of a system. Thus, the complicated motion of a free system can be described by finding the relative contribution of each normal mode to the initial displacement pattern, and by considering that the system vibrates with independent simple harmonic motions simultaneously at the natural frequency of each normal mode.

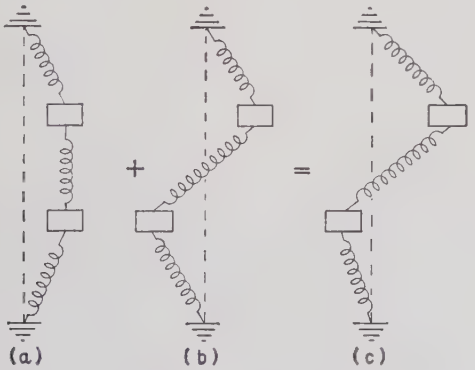

*Fig. 7—Analysis of arbitrary displacement pattern: (a) One normal-mode component; (b) A second normal-mode component; (c) Arbitrary displacement pattern, being the sum of a and b.*

When appreciable resistance is present in a coupled system, the free motion of the masses in the normal modes of vibration consists of damped harmonic vibrations rather than simple harmonic vibrations. In general, each normal mode has a different damping constant.

## DISTRIBUTED SYSTEMS AND WAVE MOTION

**Waves on a String.** The previous section described the vibrational motion of lumped systems containing individual elements of mass, stiffness, and resistance. In contrast, a stretched flexible string is a distributed system; a continuous material in which it is no longer possible to distinguish between masslike and springlike elements. The stretched string, a one-dimensional system, serves to illustrate several basic properties of wave motion without the complications encountered in systems distributed in two or three dimensions.

In describing the motion of a coupled system, as in the preceding section, it is necessary to specify the position of each mass as a function of time. Now, suppose that the number of coupled masses becomes very large and that the weight of each mass and the separation between masses becomes very small. If this process is carried far enough, the discrete coupled masses can no longer be distinguished, and the system becomes essentially a continuous elastic string with a "uniform" density. To describe the motion of this distributed system it is necessary to specify the displacement of every point along the string as a function of time, i.e., to give an equation for the displacement as a function of position as well as time.

At a given instant of time, the displacement and the phase vary from point to point along the string; with the passage of time, however, the pattern of the displacement moves along the string at a constant velocity and without change in shape. The progression of a displacement pattern constitutes a wave motion, and the ability to propagate waves of arbitrary shape is a fundamental property of distributed systems. Waves on a string and in air are propagated without change in shape, but some types of wave motion, particularly surface waves, involve a progressive change in the shape of the waves.

*Traveling Wave.* The simplest type of wave is a sinusoidal traveling wave, which can be produced in a long stretched string by moving one point with simple harmonic motion. If the driving point is moved back and forth parallel to the length of the string, the waves are longitudinal, and if the driving point is moved at right angles to the length of the string, the waves are transverse. In either case, other points in the string move with simple harmonic motion of the same frequency and amplitude as the driving point but with different values of the phase. A transverse wave travels with a velocity, $c$, given by $c = \sqrt{T/\mu}$, where $T$ is the tension in the string and $\mu$ is the mass per unit length. Thus, if the phase at the driving point is $\omega t$, the phase at a distance $x$ from the origin is $\omega(t-x/c)$, since $x/c$ is the time required for a disturbance moving with velocity $c$ to travel a distance $x$. Because of this uniform change in phase with distance, the displacement at a given instant in time varies

sinusoidally with distance; and with the passage of time, the sinusoidal pattern of displacement moves away from the driving point with a constant velocity, as shown in Fig. 8.

The distance between two points which have maximum displacement at the same time is called the wave length λ.

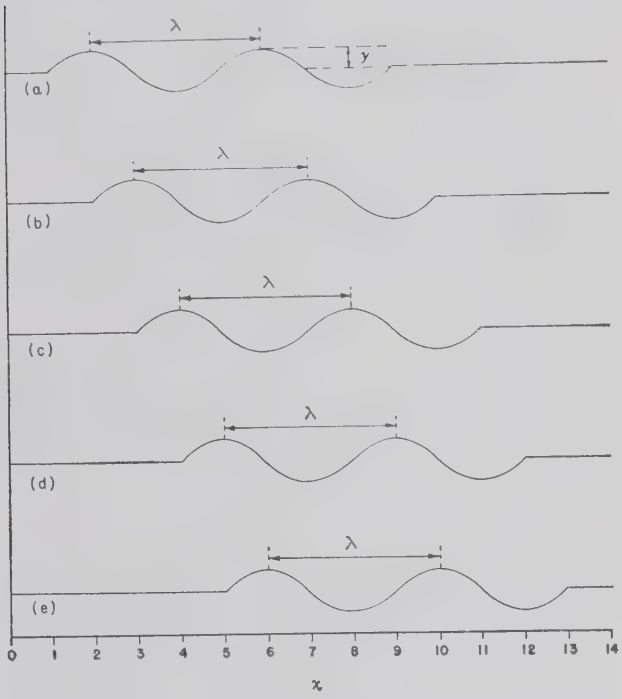

*Fig. 8—Motion of a wave train, consisting of two cycles, along a string; the time interval between the successive drawings (a,b,c, etc.) is one-fourth period, and the elapsed time between a and e is one period, T. (x) Distance; (y) Amplitude.*

The time between the arrival of successive maxima at the same point is the period, $T=1/\nu$. So, if a point of maximum displacement, or any other point in the wave pattern, travels a distance λ in a time $T=1/\nu$, the velocity must be: $c=\lambda/T=\lambda\nu$.

This fundamental relation for all sinusoidal traveling waves states that the distance a wave travels in one second is equal to the distance between successive points of equal phase times the number of such points arriving in one second. It can be seen that high-frequency waves have short wave lengths and that low-frequency waves have long wave lengths.

The force required to generate a transverse wave of a given amplitude varies with the tension and with the mass per unit length of the string. It is measured by the ratio of force to velocity, i.e., the impedance, of the driving point, which has the value: $z_o=\mu c=\sqrt{\mu T}$ (zero phase angle) for each direction of wave propagation. When the string extends in both directions away from the driving point, the impedance is $2z_o$, but when the driving point is at one end of the string, waves are propagated only in one direction and the impedance is $z_o$. In other words, a wave train in a very long string has a resistance which is constant for all frequencies in the same way as a lumped resistance element. The value, $z_o$, of the impedance of a driving point in a very long string is known as the characteristic impedance of the string.

It is implicit in the idea of a traveling or progressive wave that the ends of the string are sufficiently distant to have no influence on the waves being considered. In general, however, an end has the effect of reflecting a traveling wave. The ends of a stretched string are usually connected to a lumped mechanical system such as a large mass, a stiff spring, or some combination of such elements. When the impedance of the termination is very large compared with the characteristic impedance of the string, the end of the string does not move appreciably, and the reflected wave has the same amplitude as the incident wave but differs by 180 deg. in phase. At an end that moves freely, the reflected wave has the same phase as the transmitted wave.

*Standing Wave.* When two waves traveling in opposite directions encounter each other, the resulting displacement of the string is simply the sum of the displacements which would occur independently in each wave. After the wave trains have passed each other, they are entirely unaffected by the encounter. Each wave maintains its identity independent of the other, but in regions where two waves are present at the same time, the waves are superposed. The superposition of sinusoidal waves having the same frequency and amplitude but traveling in opposite directions results in a type of motion known as a standing wave, as illustrated in Fig. 9. Certain points, called nodes, have zero amplitude, since the displacements of the two waves are always 180 deg. out of phase at these points and therefore cancel each other. Midway between two nodes, the displacements of the two traveling waves are alternately in phase and out of phase; here the displacement amplitude of the string is twice the amplitude of either wave independently. Such points are called antinodes or loops. The distance between adjacent nodes is half a wave length, and the distance between a node and an antinode is a quarter of a wave length. When the end of a string is connected to a rigid (high-impedance) structure, a node occurs at the end, but when the string has a low-impedance termination, e.g., a long light spring, an antinode occurs at the end. In either case, nodes and anti-

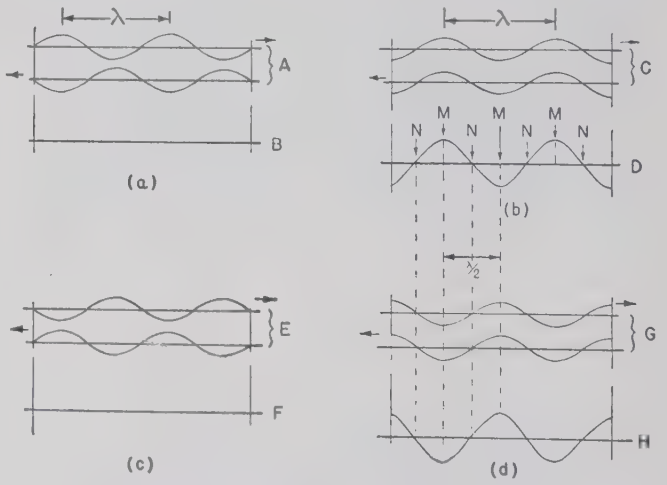

*Fig. 9—ADDITION OF TWO TRAVELING WAVES; OF EQUAL FREQUENCY AND EQUAL AMPLITUDE, TO FORM A STANDING WAVE*

*(a) Waves cancel each other completely, and their sum is zero*
*(b) Waves having progressed in opposite directions by a quarter wave length; they are in phase and add to give positive and negative displacements of twice the value in each wave*
*(c) Waves having progressed in opposite directions by a half wave length; they are opposite in phase and cancel each other*
*(d) Further travel of an additional quarter wave length results in a relationship that is similar to that in b but out of phase with the latter by 180°*
*(A,C,E,G) Traveling waves; (B,D,F,H) Sum; (M) Anti-node; (N) Node*

nodes occur successively every quarter wave length along the string.

*Natural Frequencies.* Consider, now, the effect of a second boundary point. Suppose that a string is stretched tightly between two immovable points a fixed distance apart. A traveling wave on the string is reflected first at one end and then at the other, so that each boundary point produces a standing wave pattern with a nodal point at the end. However, nodal points always occur at intervals of half a wave length. In order to satisfy both of these conditions, it is necessary that the distance between the fixed points be an integral number of half wave lengths. Thus, a string which is fixed at both ends cannot carry out free vibrations except at those frequencies for which the length of the string is an integral multiple of the half wave length. These frequencies are called the natural frequencies of free vibration, and associated with each natural frequency there is a characteristic standing-wave pattern that constitutes one of the normal modes of vibration of the string. The fundamental frequency occurs when there is only one loop between the nodes at each end, the length of the string is $L = \lambda/2$, and the frequency is $\nu_1 = c/2L = \sqrt{T}/2L\sqrt{\mu}$. As an example, the D string on a violin has a vibrating length of 33 cm. and a mass per unit length of 0.0115 gram per centimeter. When the tension on this string is $4.32 \times 10^6$ dynes per centimeter, the fundamental frequency is:

$$\frac{1}{2 \times 33}\sqrt{\frac{4.32 \times 10^6}{0.0115}} = 294 \text{ c.p.s., the frequency of D.}$$

The second harmonic frequency is twice the fundamental and the corresponding normal mode has two antinodes and one node between the nodes at the ends. Higher natural frequencies occur at each multiple of the fundamental frequency, forming an harmonic series. The normal modes of vibration corresponding to the first four natural frequencies are shown in Fig. 10.

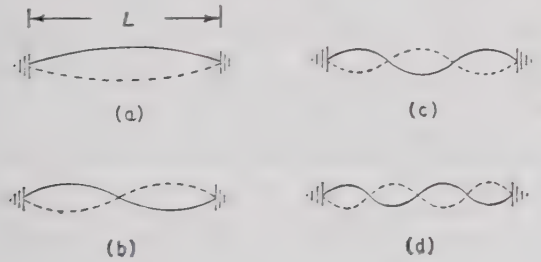

*Fig. 10—Normal modes of vibration associated with the first four natural frequencies of a string of length L fixed at both ends: (a) Fundamental ($\nu = \sqrt{T}/2L\sqrt{m}$); (b) Second harmonic ($\nu_2 = 2\ U_1$); (c) Third harmonic ($\nu_3 = 3U_1$); (d) Fourth harmonic ($\nu_4 = 4U_1$).*

As in the case of the free vibrations of a coupled system, the free vibration of a string released from an arbitrary initial displacement is very complicated. It can be described, however, by analyzing the initial shape of the string into components which follow the patterns of the various normal modes, in a manner similar to the Fourier analysis of complex wave forms. Each normal mode component then vibrates in its own characteristic standing-wave pattern at its own natural frequency. At a given instant, the displacement of any point on the string is the sum of the component displacements in the standing-wave motion of each of the normal modes.

*Bounded System.* A string rigidly terminated at one end and driven at the other end by a sinusoidal force of constant amplitude provides an example of the forced motion of a bounded system. There is no limitation on the frequencies of the waves that can be propagated on the string; every point on the string moves with simple harmonic motion at the frequency of the driving force. The presence of one rigid boundary causes a standing wave system with a node at the fixed end of the string; other nodes occur at intervals of half a wave length along the string. As the driving frequency is varied, the wave length changes and the nodal points move along the string in order to maintain a separation of half a wave length. Thus, depending on the wave length and the length of the string, the driving point may be at a node, at an antinode, or at any intermediate position. When the driving point is near a node, the amplitude at that point is small; the nodes are points of high impedance. The antinodes, however, are points of low impedance, since here the applied force causes a relatively large displacement at the driving point. As the frequency changes, the impedance at the driving point varies in a periodic manner. The frequencies of minimum driving point impedance are resonant frequencies, and the shape of the string at each of these frequencies is the same as the corresponding normal mode of vibration of a string fixed at one end and free at the other.

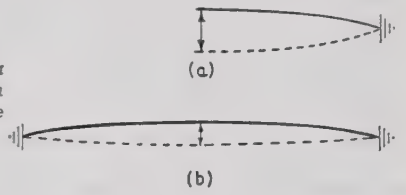

*Fig. 11—The case of a string fixed at both ends and driven in the middle*

The case of a string fixed at both ends and driven in the middle *b* is equivalent to the sum of two strings fixed at one end and driven at the other *a*. The driving-point impedances of the two component strings add, so the impedance of a string fixed at both ends and driven in the middle is twice that of a string half the length driven at one end, as illustrated in Fig. 11. The resonant frequencies of a string fixed at both ends occur at those frequencies for which the wave length is twice the distance between the two fixed ends.

**Wave Motion in Gases, Liquids, and Solids.** *Longitudinal Waves.* The wave motion of three-dimensional systems is necessarily more complex than the wave motion of a one-dimensional string, but there are many close analogies between waves on a string and waves in air, water, or solid bodies. In the discussion of strings, attention is focused chiefly on the propagation of transverse waves, since the transverse motion of a string is more readily observed than the longitudinal motion. However, the wave effects described also occur for longitudinal displacements. A longitudinal wave is associated with compression and expansion of the material while a transverse wave is associated with bending. A solid material, such as steel or rubber, can propagate either transverse or longitudinal waves. The two types of waves are transmitted with different velocities, since the compressive stiffness of a solid is different from the stiffness under bending. But in a fluid such as water or air, only longitudinal waves can be propagated, since it is not possible to "bend" a gas or a liquid.

In a longitudinal wave, the displacement of the particles from their equilibrium positions causes local regions of high pressure and low pressure. The difference between the instantaneous value of the total pressure at a point and the average value of the static pressure is called the sound pressure or the excess pressure; but since the static pressure is of relatively little concern in acoustics, the word "pressure,"

without the qualifying adjective, usually refers to sound pressure. The sound pressure takes on both positive and negative values and, over any extended period of time its linear average is zero. In an unconfined medium, the value of the excess pressure is proportional to the gradient (the spatial rate of change) of the displacement, so the regions of maximum and minimum pressure occur where the displacement is changing most rapidly. In a single-frequency compressional wave, the sound pressure and the displacement both vary sinusoidally with distance at a given instant of time, but the pressure leads the displacement by 90 deg. in phase.

*Intensity.* In order to produce sound pressure, it is necessary to disturb a condition of stable equilibrium in the medium. Consequently a sound source must supply energy to the medium in order to generate a sound wave. As the disturbed regions move away from the source in the form of a sound wave, they carry energy with them, so that there is a continuous flow of energy from the source into the medium. The amount of energy passing through a surface of unit area in one second is called the intensity of the sound wave. In a traveling wave which is several wave lengths away from its source, the intensity is proportional to the square of the sound pressure. At a given point in space, the intensity has not only a magnitude, but also a direction, so that it is a vector quantity. Since the intensity is the rate of energy flow, it represents power; it is usually measured in watts per square centimeter.

The magnitudes of the quantities involved in an audible sound wave are very small. For example, the minimum audible sound at 1,000 c.p.s. has the following characteristics:

| | | |
|---|---|---|
| Pressure amplitude | $=2\times10^{-4}$dynes/cm.$^2$ | or $3\times10^{-9}$lb./in.$^2$ |
| Displacement amplitude | $=8\times10^{-10}$cm. | or $3\times10^{-10}$in. |
| Velocity amplitude | $=5\times10^{-6}$cm./sec. | or $2\times10^{-6}$in./sec. |
| Intensity | $=10^{-16}$watts/cm.$^2$ | |

The intensity of a sound wave is sometimes expressed as a logarithmic ratio by the relation $N = 10 \log_{10} (I/I_0)$, where $N$ is the number of decibels (db.), $I$ is the intensity, and $I_0$ is the reference intensity ($I_0 = 10^{-16}$ watts/cm.$^2$). On the decibel scale, the minimum audible sound at 1,000 c.p.s. is approximately 0 db., and a 1,000-c.p.s. sound becomes painful at an intensity level of about 120 db.

A painfully loud sound at 1,000 c.p.s. has the following characteristics:

| | | |
|---|---|---|
| Pressure amplitude | $=2\times10^2$dynes/cm.$^2$ | or 0.003 lb./in.$^2$ |
| Displacement amplitude | $=0.0008$ cm. | or 0.0003 in. |
| Velocity amplitude | $=5$ cm./sec. | or 2 in./sec. |
| Intensity | $=10^{-4}$watts/cm.$^2$ | |

*Velocity.* For small changes in pressure, the compressional stiffness of the air is quite accurately proportional to the static pressure, and the general relation for the velocity of a wave, i.e., $\sqrt{\text{stiffness/mass}}$, in air is: $c=\sqrt{P_0\gamma/\rho}$, where $c$ is the wave velocity, $P_0$ is the static pressure (about $10^6$ dynes per square centimeter at one atmosphere), $\rho$ is the density (0.0012 gram per cubic centimeter for normal air) and $\gamma$ is a constant with a numerical value of 1.4 for normal air ($\gamma$ is the ratio of the specific heat of air at constant pressure to the specific heat at constant volume). The quantity $P_0\gamma$ is the stiffness of a unit volume of air and $\rho$ is the mass of a unit volume. The velocity of sound also varies with temperature since the density and pressure of air both change with temperature. At a pressure of one atmosphere and at 32° F., the velocity of sound in air is 1,088 ft. per second (332 meters per second), or about 740 m.p.h. The velocity increases about one foot per second for each degree Fahrenheit of increase in temperature.

When air particles are permitted to move only in one dimension, as in a long straight tube, there is a complete analogy between the wave motion of the air and the wave motion of a string. A one-dimensional wave motion in a three-dimensional medium is known as a plane wave, since the behavior of the medium is uniform over any plane perpendicular to the direction of wave propagation. In a three-dimensional medium, it is necessary to make a modification in the concept of impedance, since a driving force cannot be applied to a point but must be distributed over an area. Hence the three-dimensional impedance is defined as the ratio of pressure (force per unit area) to velocity, instead of force to velocity. The ratio of pressure to velocity is called unit-area impedance as distinguished from the ratio of force to velocity, which is called mechanical impedance. The impedance of a very long column of air of unit area to plane wave motion is the characteristic impedance of air; it is commonly designated by the expression $\rho c$ (pronounced "rho-see"), since it is the product of the density, $\rho$, and the velocity of sound, $c$. The $\rho c$ of air is a pure resistance, and for normal air its numerical value is such that a pressure amplitude of 42 dynes per square centimeter produces a velocity amplitude of 1 cm. per second.

In a string, a wave motion is described by specifying the displacement of every point as a function of time. To describe wave motion in air, it is usually more convenient to specify the pressure as a function of time and position, since this quantity is more easily measured than the displacement.

*Vibrations of Air in Tubes.* The free plane wave vibrations of air in short tubes resemble very closely the free vibrations of a string bounded at two points. When one end of a tube is terminated by a rigid wall, the displacement must vanish at that wall, so that a displacement node always occurs at the closed end of a tube. This corresponds to a point of maximum pressure. At an open end, the boundary condition is such that the sound pressure must vanish, so that the displacement has a maximum value here. The free vibration of air in a short tube involves a sinusoidal variation of displacement and pressure with time at one of the natural frequencies of the tube.

A tube open at both ends or closed at both ends can propagate only those frequencies for which the length of the tube is an even multiple of the half wave length.

A tube open at one end and closed at the other has a displacement node (pressure maximum) at the closed end and a displacement antinode (vanishing pressure) at the open end. The fundamental frequency of such a tube occurs when the length of the tube is one-quarter of a wave length; the second natural frequency occurs when the length of the tube is three-quarters of a wave length, and higher frequencies occur when the length of the tube is an odd multiple of a quarter wave length. The forced motion of sound in uniform tubes also parallels very closely the forced motion of a bounded string.

The natural frequencies of a closed or open organ pipe are calculated in the same way as for fixed and free strings, except that the velocity of sound in air replaces the wave velocity on strings. For example, the fundamental natural frequency of an "8-foot closed" organ pipe at 70° F. is $\gamma_1 = c/2L = 1{,}120/(2\times8) = 70$ c.p.s., about two octaves below middle C. An "8-foot open" pipe is one-quarter wave length long at the fundamental instead of half a wave length, so its fundamental is about 35 c.p.s., or three octaves below middle C.

*Plane Wave Motion.* It has been assumed in the discussion above that the particles of the medium were constrained to move in a single dimension by being confined in a long straight tube. Plane wave motion can also occur when a driving pressure is applied uniformly over a large area. The air particles in front of the plane are carried along with it, and a region of high pressure is built up in front of the plane. Near the boundaries of the plane the pressure is somewhat relieved by flow around the edges, but near the center of the plane the air particles can only move directly away from the plane. Thus, in front of the center of a large plane surface, the particles of air are effectively limited to a one-dimensional motion as the plane moves back and forth.

*Motion of Air in a Nonuniform Tube.* More generally, however, motion of the particles can occur in three dimensions. An example of such motion is provided by the behavior of air in a nonuniform tube, with a cross-sectional

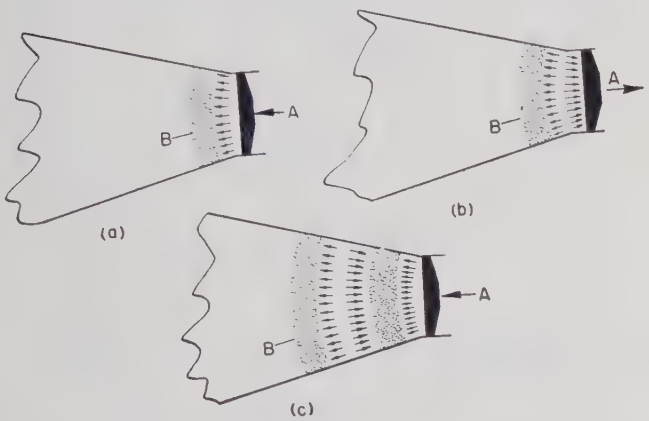

*Fig. 12—MOTION OF AIR IN A NONUNIFORM TUBE*

*(b) High-pressure region moving out, and piston moving in opposite direction*
*(c) Piston creating a second region of high pressure*
*(A) Direction of piston; (B) High-pressure region*

area that changes with distance. Consider a flat piston moving with simple harmonic displacement in the small end of a flared tube, as shown in Fig. 12. As the piston moves forward, the air particles are displaced and a region of high pressure occurs over its face. As the resulting sound wave moves along the tube, the volume occupied by the high-pressure region increases because of the increase in the cross-sectional area of the tube. As a consequence, the maximum pressure in the high-pressure region diminishes as the wave moves along the tube. This reduction in the pressure of traveling sound wave, due to an increase in the area of the wave front, is called geometrical attenuation. Whenever the area covered by a traveling sound wave increases as the wave progresses, the intensity of the wave must decrease, since the product of the area and the intensity remain constant, i.e., the sound energy flowing into any closed volume is equal to the sound energy flowing out of this volume. In the case of a conical horn or of a small source radiating in all directions into free space, the geometrical attenuation causes the pressure to decrease in inverse proportion to the distance from the source, and the intensity is said to vary as the inverse square of the distance from the source.

*Reflection in Three-dimensional Wave Motion.* The phenomenon of reflection is also more complicated in three-dimensional wave motion than in one-dimensional wave motion. In general, reflection occurs whenever a sound wave encounters a surface with a different characteristic impedance. The intensity of the reflected wave $I_R$ depends on the characteristic impedance of the medium $Z_1$ and the characteristic impedance of the reflecting surface, $Z_2$:

$$\frac{I_R}{I_I} = \left(\frac{Z_2 - Z_1}{Z_2 + Z_1}\right)^2 ,$$

where $I_I$ is the intensity of the incident wave. The value of $\rho c$ for air is 42 in c.g.s. units, whereas the value of $\rho c$ for a typical liquid is about $5 \times 10^5$ and for a typical solid, about $1.2 \times 10^6$. Consequently, any continuous surface of a liquid or a solid provides an almost perfect reflector for sound waves in air.

Surfaces that are much larger than the wave length reflect sound according to the familiar law of optics, that the angle of reflection is equal to the angle of incidence. Thus, when a plane sound wave encounters a large smooth obstacle, the direction or directions in which the sound wave is reflected may be determined by thinking of the sound wave as a beam of light and the obstacle as a mirror. However, when any dimension of the reflecting surface becomes comparable in size with the wave length of the sound, the situation is much more complicated. The wave reflected under such conditions, even from a plane surface, is scattered, i.e., reflected simultaneously in all directions.

Since the wave lengths of audible sound in air range from about 50 ft., at 20 c.p.s., to about ¾ in., at 20 kilocycles, common objects of moderate dimensions generally reflect high-frequency sounds like a mirror but scatter low-frequency sounds. Hence, the behavior of a sound wave containing many frequencies when it encounters an irregular obstacle of moderate dimensions is highly complex.

**Radiation of Sound.** In the previous section it is pointed out that a very large plane surface moving back and forth through the air with simple harmonic motion produces a plane wave in front of the central region of the surface. This is a somewhat idealized case, since no actual plane surface can be indefinitely large. To give a complete description of the production of sound, it is necessary to take account of the motion of the air particles around the edges of the radiating surface.

*Simple Source.* Theoretically, edge effects are eliminated only in the case of a sound source having complete symmetry, e.g., a small sphere with a radius that changes sinusoidally with time. Such a "breathing" sphere is called a simple source. Because of the symmetry, the particle displacement at any point takes place along a radial line, and the sound waves move out as spherical surfaces with a constantly increasing radius. As mentioned in the previous section, the sound intensity falls off as the inverse square of the distance from the center of a sphere and the sound pressure falls off as the inverse first power of the distance from the sphere. Any mechanical system which undergoes a periodic change in volume can be considered a simple source for sounds which have wave lengths much longer than the maximum dimension of the system. Thus, at a frequency of 100 c.p.s., a loudspeaker mounted on one surface of an airtight box, 12 in. on a side, is effectively a simple source, since the wave length, 11 ft., is considerably greater than the dimensions of the source, 1 ft.

*Directionality.* Suppose now that two simple sources are located near each other, as shown in Fig. 13; that they are changing in volume by the same amount and at the same frequency; and that they both have maximum volume at the same time. Each source radiates a spherical wave and, by the principle of superposition, the sound pressure at any

point is the sum of the pressures due to each source independently. In some directions, the pressure maximum in the wave train from one source arrives at the same time as the pressure maximum in the wave train from the other source, so that the two waves add together to give twice the value of

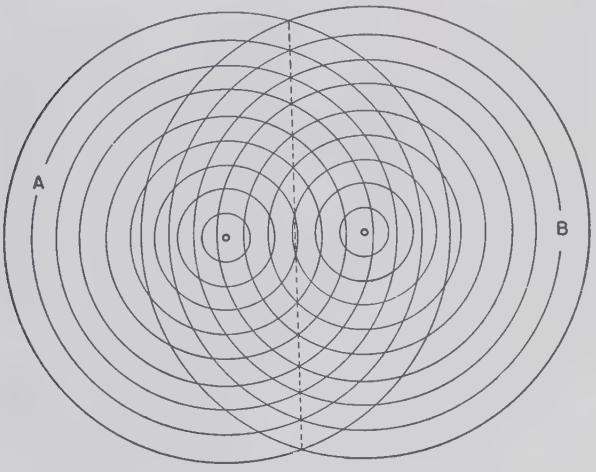

*Fig. 13—INTERFERENCE PATTERN OF TWO SOURCES OF EQUAL AMPLITUDE*

*(A) Wave fronts from left-hand source; (B) Wave fronts from right-hand source*

the pressure of either source independently. In other directions, however, the pressure maximum from one source arrives at the same time as a pressure minimum from the other source so that the two sources cancel each other completely in these directions. The distribution of sound around

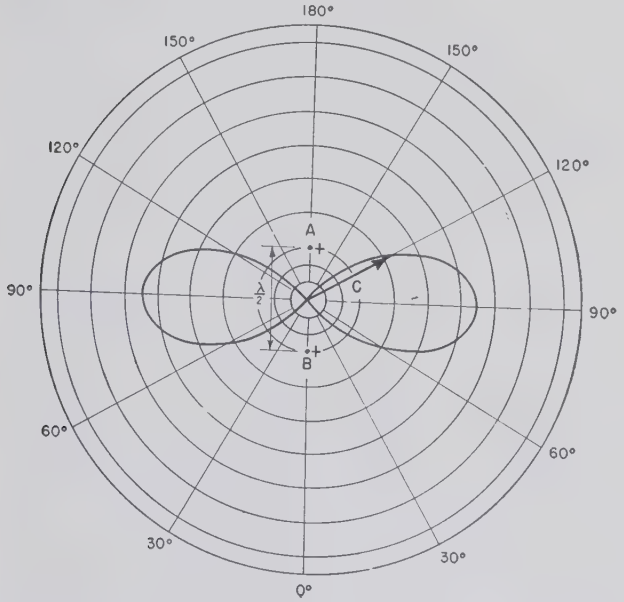

*Fig. 14—DIRECTIVITY PATTERN OF TWO SOURCES IN PHASE AND HALF-WAVE LENGTH APART*

*(A and B) Two sources; and (C) Intensity of sound radiated to a particular point on the curve*

the two sources now has directionality, since the intensity of the radiated sound depends on direction. When two equal sources in phase with each other are located half a wave length apart, the intensity of the radiated sound varies with direction in the manner shown in Fig. 14; two out-of-phase sources located half a wave length apart behave as shown in Fig. 15.

Very complicated directionality patterns can be obtained by various arrangements of the phase relations and the separations between a small number of simple sources. Such a planned arrangement of sources is called an array.

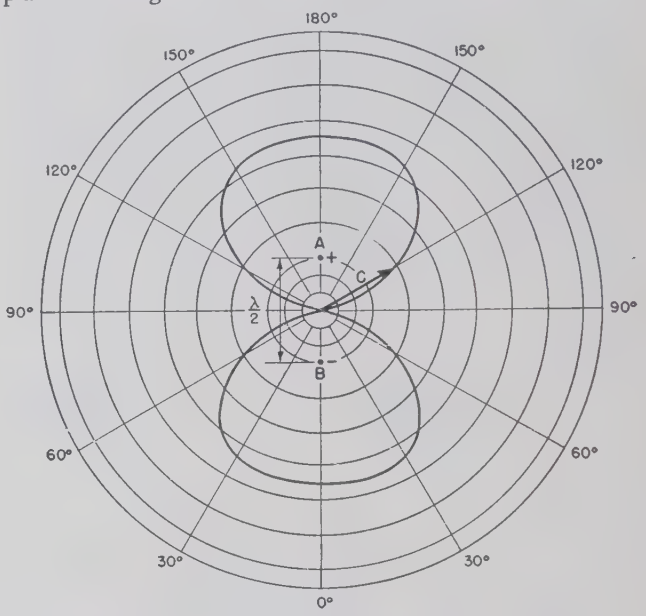

*Fig. 15—Directivity pattern of two sources 180° out of phase and half-wave length apart: (A and B) Two sources; (C) Intensity of sound radiated to a particular point on the curve.*

*Effect of Source on Radiation.* In many cases of interest, however, the dimensions of a source are comparable with the wave length of the radiated sound. This is true, for example, of a 10-in. loudspeaker operating in the frequency region between 500 and 2,000 c.p.s. ($\lambda$=2 ft. to 6 in.). In such cases, the directivity of the radiated sound depends, in a very com-

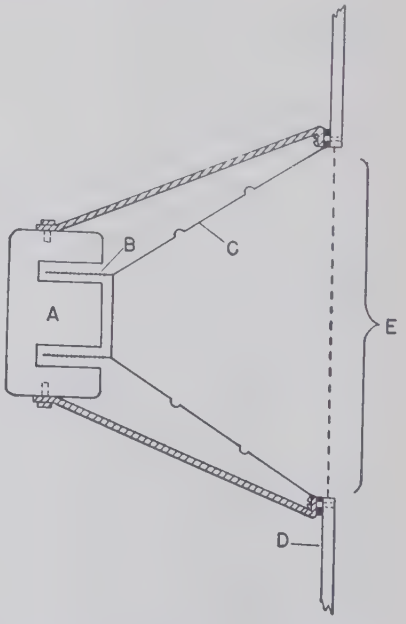

*Fig. 16—Details of a dynamic speaker; (A) Magnet; (B) Coil; (C) Cone; (D) Large baffle; (E) Equivalent piston.*

plicated way, on the ratio of the dimensions of radiator to the wave length, and on the arrangement and size of any reflecting surfaces in the neighborhood of the radiator.

Loudspeakers are frequently mounted in a large, flat re-

flecting surface (a baffle). In this arrangement, the speaker is approximately equivalent to a plane piston moving with the same volume displacement as shown in Fig. 16. The directionality of the speaker can be calculated, within this approximation, by considering every point on the surface of the piston to be a simple source and adding together the contributions from the entire collection of simple sources.

The directionality of high-frequency radiation can be noticed easily with a conventional radio or phonograph. The low-frequency sounds are more or less uniformly spread around a room, but the high frequencies, which contribute to brilliance, are concentrated directly in front of the loudspeaker. Flared and sectionalized horns (tweeters) are sometimes used to spread high-frequency sounds more widely.

At a given frequency, the total power radiated depends directly on the area of the radiating surface. At low frequencies, when the wave length is large compared with the radius, all sources are relatively poor radiators. In order to increase the total power radiated and to decrease the frequency at which the wave length is comparable with the diameter, dimensions of a radiator should be as large as possible. The effective size of a radiator is frequently increased by the use of a horn. In a small, partially closed speaker, such as the one shown in Fig. 17, it is possible to develop relatively high sound pressures. A horn, arranged as shown, distributes this pressure uniformly over a relatively large area and, thus, provides a more efficient radiator than a speaker unit alone.

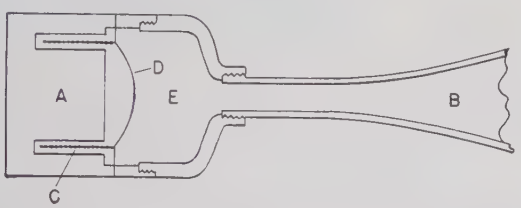

*Fig. 17—Dynamic speaker coupled to an exponential horn: (A) Magnet; (B) Horn; (C) Coil; (D) Diaphragm; (E) Air volume.*

*Effect of Radiation on Source.* Only the effect of source shape and dimensions on the radiated sound have been considered. An additional aspect of the general question of radiation lies in the effect of the radiation on the source. In general, sound sources consist of lumped mechanical or electromechanical systems, and the motion of these systems may be treated by the methods described under Simple Vibrating Systems. However, when a mechanical system radiates sound energy, this fact must be taken into account in the description of the mechanical motion, since the mechanical and the acoustical aspects of the problem are intimately coupled.

The effect of radiation on a mechanical system is to add a radiation impedance to the previously existing mechanical impedance of the system. In terms of the mechanical system, the added impedance is given by the area of the radiating surface times the acoustic impedance at that surface. When the radiated sound is transmitted away from a simple source, the impedance added to the mechanical system is a pure resistance, but when reflecting surfaces, tubes, or horns are used as part of the radiating system, the radiation impedance added to the mechanical system may include an effective stiffness or an effective mass as well as a resistance. *See also* Acoustics; Ultrasonics; Vibration.

**SOUND-RECORDING SYSTEMS.** *See* Acoustics (*Electroacoustics*).

**SOUND SYMBOLISM,** also called *symbolic phonetics,* that correspondence between the sound and meaning of words which lies outside the realm of onomatopoeia, or sound imitation. The reasons for a correspondence of this kind are not clear, but the phenomenon is so widespread and attested by so much material from all languages that its existence is undeniable.

Ferdinand de Saussure observed that Latin adjectives indicating diseases or deformities of the body contain almost regularly the vowel *ă* (e.g., *caecus, calvus, claudus, crassus, laevus, paetus, parvus, paucus, paulus, plautus, raucus, scaevus,* etc.). This is true not only in Latin, but in Primitive Indo-European too; and it may be added that the vowel *ă* is very rare in that language and that it is outside of the general vocalic system, since it does not take part in the general apophony of all other vowels. There is no question of onomatopoeia in this case, nor can it be said that sick or deformed persons have any preference for the vowel *ă,* or that *ă* is in any other way connected with disease or deformity. The fact remains unexplained, but its existence is well established.

Another clear case of symbolism is presented by *č* (written *tsch*) in German. This sound is entirely outside of the phonemic system of German consonants; it does not go back directly to any Indo-European sound either through Grimm's Law or Verner's Law, and it did not exist in Old High German. It crept slowly into Middle German in a few words of French origin, reproducing the French *ch,* which was at that time pronounced *č* (e.g., *tschevalier, tschamber,* from French *chevalier, chambre*). In Modern German the sound is rather frequent, occurring not only in words of foreign origin, such as *Gletscher, Peitsche, Kutscher, Patschuli,* and *Tschech,* but also in German words that are either recent creations or modifications of old German forms. These words may be divided into two classes: onomatopoetic words (e.g., *zwitschern,* "to twitter"; *klatschen,* "to gossip"; perhaps *rutschen,* "to slide") and expressive or affective words, frequently with a pejorative tinge. Among the latter are *Quatsch,* "nonsense"; *Kitsch,* "daub"; *Patsche,* "puddle"; *patschen,* "to slap," "to splash"; *Putsch,* "political outbreak"; the interjections *ätsch! ritsch! ritsch ratsch!* and, in a very different tone, several words meaning "caress" or "fondle," among them *hätscheln, tätscheln,* and *knutschen.* By no stretch of the imagination can onomatopoeia be found in some of the words in this second category.

The same sound *č* has doubtless an expressive symbolic value in other languages, usually indicating, as in German, something despicable. Spanish has the sound in the endings *-acho, -echo, -icho, -ucho,* and the pejorative Italian suffixes *-iccio, -uccio,* and *-accio* have *čč,* which no other suffix has. In all these languages, *č* is also frequent in affective diminutives from personal names, even where the original name does not have the sound, as in German *Tschatzi* (=*Schätzchen*), Spanish *Chabel* (from *Isabel*), and Italian *Cicci, Ciccio* (from *Francesco*). In Spanish, as in German, there is no "etymological" reason for initial *č-* except in a few foreign words, and it is therefore exclusively onomatopoetic or expressive.

The expressive value of the consonant *l* was recognized by Plato, whose ideas on the subject were developed later by Wilhelm von Humboldt and Otto Jespersen. Plato called attention to the presence of the sound in the Greek words for "smooth," "gliding," "sleek," and "glutinous." It is significant that three of these words have the *l* sound in English also, and there are innumerable examples in English of words that express the idea of gliding with this same sound, e.g.,

*flow, flag, flake, flutter, flicker, flurry, flit, fling, fly, flee, float, slide, slip,* etc.).

Perhaps the clearest case of sound symbolism is presented by the vowel *i,* which is frequently found in the words that indicate something small. Plato noticed this phenomenon also, and there is a vast amount of material now available to illustrate it. A few examples are *little, wee, bit, whit, skimpy,* and the Shakespearean *minikin;* for animals or persons, *kid, chick, kitten, shrimp, filly;* and for small objects, *twig, sprig, chip, strip, tip, pip,* etc. The vowel *i* is particularly frequent in diminutive suffixes and pet-names, especially feminines, and this is true in all languages. Thus English has *auntie, baby, laddie, Dolly, Dicky;* Spanish has *animalico, perrito, mujercita, hombrecillo;* Italian has *bambino, animalino, cagnolino;* and Greek has *παιδίον.* It is significant that many of the Romance suffixes are either new creations or, like *-inus,* had another meaning in Latin and became diminutives because of their sound.

As opposed to *i* (and in some degree *u*), the full vowels *a* and *o* frequently indicate something big. As against *-uccio* and *-ino,* Italian has *-accio* and *one.* "Small" is *petit* in French, *chico* or *pequeñito* in Spanish, and *piccolo, piccino,* and even *piccinino* in Italian (all new creations), while "big" is respectively *gros* or *grand, gordo* or *grande, grosso* or *grande.*

This opposition of *i* or *u* to *o* and *a* appears also in many words of the type *ping-pong, chitchat, zigzag, flic flac, kling klang*—a type that is fairly frequent in many languages of the world. In these formations, it is always the first member that has the *i,* the second one the *a* or *o* (always *ping-pong,* never *pong-ping*). There is certainly a connection between this opposition and that found in adverbs and pronouns expressing the concepts *near* and *far.* The word indicating something near usually has the vowel *i,* while the word indicating something far has the more open vowels *a, o,* or sometimes *e* (Eng. *this:that, here:there;* Ger. *dies:das, dieser: jener;* Fr. *ici:là, celui-ci: celui-là;* Sp. *allí: allá,* etc.).

Despite the frequent recurrence of some of these instances of symbolism, it should be remembered that no regularity can be attributed to the phenomenon. Some sounds are symbolic in some words and not in others, as the vowel *i* in English sometimes indicates a small object but often does not; and conversely, objects are not always indicated by a symbolic sound. Thus in English, from the point of view of sound symbolism, the vowels in *big* and *small* should be reversed and those in *thick* and *thin* should be differentiated. Nevertheless, the evidence is sufficient to prove that phonetic symbolism exists, even though it is not found in all the words in which it might be expected to occur.

Sound symbolism may sometimes be found in conflict with the normal processes of phonetic change. Thus, the vowel *i* in Old English *micel* was transformed to the rather open and obscure vowel of Modern English *much,* a sound that better expresses the meaning of the word. Likewise the word *great* had the vowel *i* until the eighteenth century, and doubtless underwent change for symbolic reasons. *Tiny* had once a symbolic *i,* which became *ai* as in all other words of its type (*mine, wine, shrine, mite,* etc.) and thereby lost its expressive value; but women and children have re-established *teeny.* Even *little,* as normally pronounced, is sometimes considered insufficiently expressive and is replaced by *leetle,* with a longer, narrower, and higher *i.*

Poets, and writers in general, use sound symbolism much more than is usually realized. In *Gulliver's Travels,* Jonathan Swift gave the name *Lilliput* to the land of the dwarfs and *Brobdingnag* to the land of the giants; among the giants, Gulliver himself, being small, is called *Grildrig.* Furthermore, it is possible to observe the liquid effects that a multitude of poets have secured by the use of the sounds *l, r,* and *n,* and to be aware of the contrast between the "light" vowels *i, u,* and *e* and the "somber" vowels *o* and *a* when these sounds are abundant in a few lines of verse. A famous example of sound symbolism in French poetry is Paul Verlaine's

*Les sanglots longs*
*des violons*
*de l'automne*
*blessent mon coeur*
*d'une langueur*
*monotone.*

There is also a remarkable contrast between lightness and gloom in the sound of the two following passages from the *Divine Comedy*:

*quale ne' plenilunii sereni*
*Trivia ride tra le ninfe eterne*
*che dipingon lo ciel per tutti i seni . . .*

*Dopo la dolorosa rotta, quando*
*Carlomagno perdè la santa gesta*
*non sonò sì terribilmente Orlando*

Such examples might be multiplied indefinitely. In many cases onomatopoeia undoubtedly plays a part, but some of the effects of sound symbolism in poetry have eluded all efforts to trace them to that source.

Attempts have been made to explain sound symbolism, or at least some of its manifestations, but none of them have been accepted as wholly satisfactory. It has been argued, for example, that small animals make shrill sounds and large animals deeper ones, and that this explains the opposition *i:o* (*a*). Jespersen suggested that a high-pitched vowel may, as in certain African languages, be associated with small things, and a low-pitched vowel with large things. It has also been pointed out that some vowels require larger openings than others, whether between the lips or in the oral cavity, *a* and *i* being at opposite extremes. Furthermore, the relation of the couple *i:o* (in *ping-pong, ding-dong,* etc.) to the opposition *near:far* has been explained on the ground that distant sounds are less shrill than those near at hand, and that it is natural for the speaker, when he utters two such sounds in succession, to begin with the one that he feels to be nearer. The problem is further confused by the difficulty of distinguishing, in some instances, between sound symbolism and onomatopoeia.

The phenomena of sound symbolism seem to offer definite support to the ancient theory that language is a natural product, not an arbitrary convention. The concept of symbolism was all but completely discarded during the positivistic period of linguistic studies, but it has regained favor with the rise of A. Meillet and his school. Since the same symbolic phenomena are found all over the world, in the most distant and unrelated languages, they present a remarkable example of a linguistic affinity that is based not on historical contacts or common origin, but on the fundamental identity of the human spirit. G. B.

**SOURIS** [sʊ′rɪs; su′ri′], a port town in Kings Co., Prince Edward Island, Canada, situated on Colville Bay, at the eastern end of the island, 45 mi. east of Charlottetown. It is served by the Canadian National Railways. It has fisheries and is a tourist center and supply point for the vicinity. The town was incorporated in 1910. Pop. 1951, 1,183. D. F. P.

**SOURSOP** [sau′ərsɒp], a small evergreen tree, *Annona muricata,* of the custard-apple family, native to the American

tropics. The tree, which grows as high as 20 ft., is also called guanabana. It is cultivated for its edible fruits which are large, juicy, and dark green, and have short, fleshy spines. These fruits are used for jellies and preserves, and for flavoring beverages. The guanabana is naturalized throughout the tropics. J. C. Wis.

**SOUSA, JOHN PHILIP** [su′sə] (1854-1932), American bandmaster and composer, was born Nov. 6, 1854, in Washington, D. C. In his youth he studied the violin, band instruments, and music theory, and later played for five years in the United States Marine Band. At the age of seventeen he began conducting theatre orchestras and practicing composition in his spare time, and in 1880 his steadily growing reputation brought him the post of bandmaster of the Marine Band. His meticulous rehearsal technique and firm leadership restored the morale, broadened the repertory, and improved the instrumentation of this organization, raising it to an enviable position as a concert and marching band. In 1892 Sousa obtained his release from the Marine Corps and formed his own organization, which he took on tour. After a slow start this group became, under his exacting training, crisp direction, and brilliant showmanship, one of the world's most celebrated musical organizations and made many tours of America, several of Europe, and one around the world.

JOHN PHILIP SOUSA

BROWN BROTHERS

Sousa continued along the lines marked out by Patrick Sarsfield Gilmore to broaden the range of dynamics and tone color of the symphonic band by improvements in instrumentation and personnel. He also composed a great number of marches which, by virtue of their remarkable military vigor, attractive tunefulness, and brilliant instrumentation, brought him the well-deserved title "The March King." Among the most famous of these marches are *The Stars and Stripes Forever* (1897), *Semper Fidelis* (1888), *Washington Post March* (1889), and *King Cotton* (1897). In addition to his marches he wrote ten comic operas, including *El Capitan* (1896), *The Bride-Elect* (1897), and *The Free Lance* (1906), as well as suites, overtures, and waltzes. He was also the author of three novels and books of reminiscences. Sousa died March 6, 1932, at Reading, Pa. C. S. Sp.

**SOUTH, UNIVERSITY OF THE,** an accredited, privately controlled college of arts and sciences and school of theology for men, conducted by twenty-two southern dioceses of the Protestant Episcopal Church. The institution, which is coeducational in the summer session only, occupies an area of 9,350 acres in Sewanee, Tenn., in the Cumberland Mountains. The charter was granted in 1858 and first instruction was offered in 1868, the date of the founding of the College of Arts and Sciences. The Theological School was added in 1878. The degrees offered are the A.B. and the B.S. in liberal arts, the B.D. in theology, and the M.A. The library contains many interesting collections, including the Fairbanks collection on the history of Florida and other Southern states; the Houghteling collection on the Reconstruction period in the United States; and the Hudson Stuch collection on travel and exploration, particularly in Alaska. The local chapter of Phi Beta Kappa was chartered in 1926.

All students must live in the college dormitories. Scholarship aid is generous, and there is some opportunity for self-help. *For statistics see* COLLEGES AND UNIVERSITIES.

J. R. To.

**SOUTH AFRICA, UNION OF.** *See* UNION OF SOUTH AFRICA.

**SOUTH AFRICA, UNIVERSITY OF,** at Pretoria, created by the University Incorporation Act in 1916. Its immediate predecessor, the University of the Cape of Good Hope, was founded by legislative enactment in 1873 and replaced the Board of Public Examiners, established in 1858. The act of 1873 granted the property of the Board to the university council. The University Extension Act authorized the council to hold examinations outside of Cape Colony, and to admit noncolony residents to compete for scholarships and prizes offered by the Council of South Africa. The University amendment acts of 1896 and 1908 increased the membership of the council and enlarged the degree privileges of the university. The Act of 1916 incorporated the University of the Cape of Good Hope and six other colleges—Grey University College (in 1935 the University College of the Orange Free State), Huguenot University College, Natal University College, Rhodes University College, Transvaal University College, and South Africa School of Mines and Technology (also known as University College)—into the University of South Africa, the several collegiate units being known as constituent colleges.

The first University College of Orange Free State (Bloemfontein) was founded in 1885 with departments of arts, commerce and administration, education, law, philosophy and social science, and science.

Huguenot University College at Wellington, Cape Province, was founded in 1898 with departments of education, philosophy, English, African and Dutch languages and literature, domestic science and chemistry. Potchefstroom University College for Christian Higher Education in the Transvaal (Transvaal University College) was founded in 1869 and incorporated in the University of South Africa in 1921. It has departments of arts, divinity, education, science, music, commerce and administration, and social science. Rhodes University College at Grahamstown, Cape Province, opened in 1904.

The University of South Africa acts as an examining body for its constituent colleges. In 1946 the Higher Education Amendment Act incorporated the division of external studies for students from nonconstituent colleges. A. L. H-Q.

**SOUTH AMBOY** [a′mbɔi], a city in northeastern New Jersey, in Middlesex Co., 9 mi. east of New Brunswick, at the mouth of the Raritan River, opposite Perth Amboy, with which it is connected by two bridges. Truck farms are found in the surrounding area. Founded in 1835, it was incorporated as a city in 1908. In 1950 the government was the

mayor-councilmanic type. Important as a transfer point, the city ships by barge to New York and New England large quantities of hard coal received by rail from Pennsylvania. Passenger transportation is provided by the Pennsylvania Railroad and the Central Railroad of New Jersey. Located in the rich clay area, South Amboy has several terra-cotta plants. Other industries produce paint pigment, cigars, and wearing apparel. Pop. 1950, 8,422.

**SOUTH AMERICA,** the southern continent of the Western Hemisphere, the fourth in size among the continents, with an area of approximately 6,846,000 sq. mi., excluding Central America. In shape it is roughly triangular, with the greatest width in the equatorial regions of the north. The northernmost point is Punta de Gallinas, Colombia, at approximately 12° 30′ N. lat. and the southernmost is Cape Horn, Chile, at approximately 56° S. lat. Tierra del Fuego at the southern end of the continent is, outside of the Antarctic, the southernmost land mass in the Southern Hemisphere. South America lies east of most of North America. The most westerly point of the continent, Punta Pariña, Peru, 81° 28′ W. long., is at about the same latitude south as Savannah, Georgia, is north. From the eastern projection of the continent in northeast Brazil, 34° 46′ W. long., the distance across the South Atlantic to Dakar in West Africa is about 1,900 mi., or a little more than half the distance across the North Atlantic from New York to London.

**Political Divisions.** The ten republics of South America, with their approximate areas, are: Brazil, 3,286,111 sq. mi.; Argentina, 1,074,209 sq. mi.; Peru, 482,257 sq. mi.; Colombia, 439,825 sq. mi.; Bolivia, 416,040 sq. mi.; Venezuela, 352,141 sq. mi.; Chile, 286,322 sq. mi.; Paraguay, 150,516 sq. mi.; Ecuador, 101,481 sq. mi.; and Uruguay, 72,172 sq. mi. The three European colonies, British Guiana, Surinam (Netherlands Guiana), and French Guiana in northeastern South America have a total area of about 179,000 sq. mi. In most cases estimates of area contain a considerable margin of error since large parts of the continent have never been accurately surveyed. Island possessions of South American countries include the Galápagos (Ecuador) and the Juan Fernández group (Chile). Along the Caribbean coast of Venezuela are the Dutch islands of Aruba, Curaçao, and Bonaire and the British islands of Trinidad and Tobago, all of which are geologically part of South America. In the South Atlantic off the coast of Argentina are the Falkland Islands, a British dependency claimed by Argentina.

P. E. J.

## HISTORICAL GEOLOGY

**Present Physiographic Regions.** The continent of South America is divided into six major physiographic regions, as follows:

(1) The Brazilian Shield, a large region of Archeozoic and Proterozoic rocks with local areas of younger strata, which extends from the Amazon Basin southward to Uruguay and westward to the Andes Mountains.

(2) The Guiana Highlands, a highly dissected upland composed of old igneous and metamorphic rocks. Before the Paleozoic era they were probably the northern extension of the Brazilian Shield.

(3) The Amazon Basin, a great alluvial plain, extending from the eastern flank of the Andes Mountains and separating the Brazilian Shield and the Guiana Highlands.

(4) The Andes Mountains, a complicated range of folded Paleozoic and Mesozoic strata and intrusive igneous rocks, which extends along the entire western border of the continent from Panama to Tierra del Fuego.

(5) The Orinoco Basin, an alluvial plain extending from the west end of the Amazon Basin northward between the Andes Mountains and the western slopes of the Guiana Highlands.

(6) The Argentine Plateau, extending eastward from the southern Andes Mountains from Paraguay on the north to Tierra del Fuego on the south. It is a low plain to the north but becomes an elevated plateau known as Patagonia to the south.

**Archeozoic and Proterozoic Eras.** During the Archeozoic and Proterozoic eras thick sediments were deposited over the Brazilian Shield. Rocks of the same ages are present in the Guiana Highlands, and it is quite possible that the two areas were covered by the same sea. At the end of the Proterozoic era extensive uplifts and mountain building folded and metamorphosed these rocks and they were subjected to many igneous intrusions. This period of mountain building formed a large upland extending from the Guianas to southern Brazil. Extensive erosion had reduced parts of this upland to a low plain by the beginning of the Paleozoic era.

**Paleozoic Era.** In the earlier part of the Paleozoic era the Andean trough appeared along the west side of the Brazilian Shield. This trough is a persistent structure which was submerged and received marine sediments throughout much of the Paleozoic and Mesozoic eras. Another trough, the Amazon trough, developed along the trend of the present Amazon Basin and connected the waters of the Andean trough with the Atlantic. Occasionally, small marginal seas overlapped the eastern end of the Brazilian Shield and parts of the Argentine Plateau. These conditions persisted through the Devonian period, after which a general uplift of the continent occurred which extended throughout most of the Mississippian period. During the Pennsylvanian and Permian periods the seas reoccupied the Andean and Amazon troughs. At this time extensive continental sands and silts were deposited over much of the Brazilian Shield and the northern part of the Argentine Plateau. Parts of these beds are of glacial origin, indicating the presence of ice sheets in this region during the Permian period. The remains of reptiles and plants found in these continental deposits are remarkably similar to those found in the Karroo beds of the same age in south central Africa. This similarity has caused some geologists to suggest that a land bridge existed across the south Atlantic during the Permian period. At the end of the Paleozoic era another general uplift of the continent caused a general withdrawal of the seas.

**Mesozoic Era.** At the beginning of the Mesozoic era the Andean trough was again depressed and flooded by the sea. Thick marine sediments were deposited in the trough in the Triassic, Jurassic, and Cretaceous periods. The rest of the continent remained above sea level throughout the era, but many continental strata were deposited. In the Triassic period thick terrestrial sands and silts were laid down over parts of the Guiana Highlands, Brazilian Shield, and Argentine Plateau. In the southern part of the Brazilian Shield these beds were covered by extensive lava flows.

During the Jurassic and the early part of the Cretaceous, the only rocks deposited in South America were marine strata in the Andean trough, but in the later Cretaceous another series of continental sands and silts was deposited over parts of the Brazilian Shield and the Argentine Plateau. These extensive deposits contain many dinosaur remains and many fresh-water lake beds.

At the end of the Mesozoic era the thick sediments that had been accumulating in the Andean trough were folded and squeezed to form the Andes Mountains. This period of

mountain building continued into the early part of the Cenozoic era.

**Cenozoic Era.** In the early part of the Tertiary period the seas were very restricted in South America. The elevation of the Andes Mountains prevented any invasion from the Pacific. Two small seas were present at opposite ends of the continent. One of them covered the northern end of the Orinoco Basin in northern Venezuela, and the other covered the southern tip of Argentina. Toward the middle of the Tertiary period the northern Venezuelan and southern Argentine seas increased in size. Beginning at this time a secondary uplift of the Andes Mountains occurred. Erosion of the newly uplifted range caused the deposition of a tremendous amount of terrestrial sands, silts, and clays along the eastern flank of the mountains, the Amazon Basin, and parts of the Argentine Plateau. It is in these terrestrial deposits that so many of the interesting fossil remains of Tertiary mammals have been found.

At the end of the Tertiary period a general uplift of the continent caused a withdrawal of the local seas and a termination of the continental deposition. Many alpine glaciers appeared on the Andes Mountains. This glaciation was more intense in the southern part of the range where, in many places, the glaciers coalesced to form ice fields that extended eastward over parts of Patagonia and westward to the Pacific, producing the fiorded coast of southern Chile by their erosive action. At the present time the continent is still relatively high above sea level and glaciers are still active in the southern Andes. E. C. S.

## SURFACE FEATURES

**Major Land Features.** The major surface features of North and South America are broadly similar in that both have high, relatively young mountains on the west, lower, geologically older mountains on the east, and, between the mountains, extensive interior plains. Along the entire western side of South America are the Andes, which with the highlands of Venezuela form a mountainous continuation along the Caribbean coast, terminating in the island of Trinidad. In the central portion of the continent lie the plains of the Orinoco, the Amazon, and the Paraguay-Paraná-La Plata river systems. Major divisions of the highlands which occupy much of the eastern part of the continent are the Guiana Highlands north of the Amazon, the extensive Brazilian Highlands south of the Amazon, and the dry plateaus of Patagonia which occupy nearly all of the narrow southern end of the continent east of the Andes.

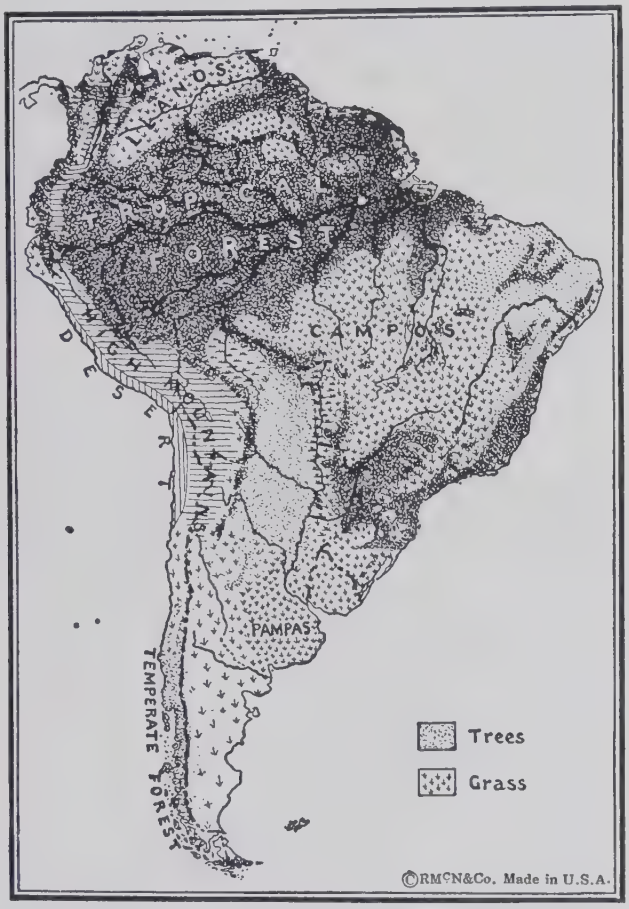
For more than 4,000 mi., from the shores of the Caribbean to the end of Tierra del Fuego, the Andes stand as a barrier between eastern and western South America. They are narrower but considerably higher than the western mountains of North America. Fifty peaks or more reach elevations of over 20,000 ft., and there are very extensive areas lying between 12,000 and 15,000 ft. above sea level. Passes are more than 10,000 ft. above sea level. South America west of the Andes is only a narrow fringe, in most sections less than 100 mi. in width. Along most of the western front of the Andes a foothill belt marks the transition from the Andes to coastal lowland or elevated coastal upland. Along the Pacific coast of Colombia and Ecuador as far south as the Gulf of Guayaquil there is a coastal lowland of swampy grassland, wide alluvial river deltas, and scattered low hills. In the north this lowland extends across the base of the Isthmus of Panama to the Caribbean, separated from the Pacific by the Cordillera del Chocó. From the vicinity of Punta Pariña southward heavy Pacific surf and geologic uplift have produced a coastline of elevated marine terraces and wave-cut cliffs. In some places the cliffs, ranging in elevation up to several thousand feet, drop off directly into the sea, while in others they appear several miles inland with the immediate shoreline occupied by sandy beaches or new marine terraces. Along the northern coast of Peru spurs of the Andes descend gradually to the sea, broken only by small river-built alluvial fans. Low coastal mountains, averaging 3,000 ft. in elevation, appear over most of the distance from southern Peru to southern Chile. In southern Peru they are backed by bleak, rock-surfaced, deeply-dissected pampas which rise gradually to the base of the Andes. Between the coastal range and the Andes in northern Chile is a longitudinal depression occupied by the series of basins which make up the Atacama Desert. From La Serena almost to Valparaiso spurs of the Andes descend to the coast, but southward for hundreds of miles the longitudinal depression appears again as the Central Valley of Chile. In southern Chile the coastal ranges appear as a series of islands and rocky promontories separated by deep fiords and arms of the sea, a region sometimes called the Chilean Archipelago. The Strait of Magellan extends from the Pacific to the Atlantic, separating Tierra del Fuego from the continental mainland.

**Central Plains.** The central plains of South America, composed largely of river- and wind-deposited materials, have in general a gently rolling surface almost entirely under 1,000 ft. in elevation. The plains are neither so extensive nor so continuous as the central plains of North America. The Orinoco plain (the llanos) is separated from the Amazon plain by a belt of highlands. The Amazon plain and the plain of the Paraguay-Paraná-La Plata are continuous in the west along the base of the Andes, where the alluvium brought down from both the Andes and the Brazilian Highlands has covered all but a few of the more prominent features of the underlying rock surface. The Amazon plain, which is wide along the eastern base of the Andes, narrows to only a ribbon of flood plain along the main stream east of Manaus where the river passes between the Guiana and Brazilian highlands.

The llanos of the Orinoco consist of a vast almost featureless savanna-covered plain approximately 600 mi. from west to east and 200 mi. from north to south. It slopes very gradually from the base of the Andes and the Venezuelan highlands to the Orinoco River. Even in the highest part it is little more than 600 or 700 ft. above sea level. The streams which cross it wind about in broad valleys with low gradients. The low mesa-like interfluves between the valleys are the most conspicuous features of the landscape. The area at the mouth of the Orinoco is a rapidly growing, low, swampy delta.

Only a small part of the vast region drained by the rivers of the Amazon system may be described as a plain. Along the lower course of the Amazon only the immediate flood plain is left as a band of lowland between the bordering highlands. Above the junction of the Rio Negro and the Rio Madeira the plain widens out in spatula fashion reaching a north-south extent of some 800 to 1,000 mi. at the base of the Andes. This wide eastern part of the Amazon Basin has been built up by materials brought down from the Andes by the Purús, the Juruá, the Yavari, and the main stream, called Solimões above the Rio Negro in Brazil and Marañón in Peru. About 10 per cent of the Amazon plain consists of river flood plain in which the soils are renewed annually by river-borne silt and the remaining 90 per cent of somewhat higher areas above flood level. The flood plain of the main stream averages about 50 mi. in width though it narrows

to about 20 mi. at Obidos and Santarém near the mouth of the Tapajós. Downstream from the junction with the Rio Xingú the plain widens out, leaving a broad area of lowland at the mouth embracing the island of Marajó and extending northward along the coast to the Guianas and southeastward to the Rio Parnaíba. The flood plain of the Amazon, like the lowlands of the Mississippi, is bordered by valley bluffs between which the river meanders in shifting channels which leave oxbow lakes and swamps.



*AREAS OF VEGETATION TYPES*

**Southern Plains.** The plains of the Paraguay-Paraná-La Plata river systems extend some 1,500 mi. from southeastern Bolivia to La Plata River. Almost all of the area is a vast featureless lowland subject to annual floods. Along the immediate river banks of the Paraguay and Paraná rivers there are natural levees high enough to stand above all but the highest floods. Back of the levees are marshy areas filled with stagnant water which barely drains away even in the dry season. West of the Paraguay River lies the vast alluvial plain of the Gran Chaco, composed of unconsolidated sands and clays brought by rivers from the erosion of the Andes. The Pilcomayo, Bermejo, Salado, and Dulce rivers cross the Chaco with winding, shifting courses, in a pattern of braided channels, crescent-shaped swamps and abandoned levees. South of the area drained by the Paraguay-Paraná-La Plata system but continuous with it are the Argentine Pampas, vast plains, level to gently undulating, mantled to a depth of hundreds of feet by an accumulation of unconsolidated beds of sand, clay, silt, and wind-blown dust, or loess, absolutely gravel free. There are almost no rivers or natural drainage courses. Numerous small ponds and sloughs, salinas in the drier west, dot the landscape.

**Eastern Highlands.** Much the greater part of eastern South America is occupied by highlands, which extend with few interruptions from southern Colombia and Venezuela across Brazil to the northern bank of the Plata and appear again in Patagonia. The highlands have a base of ancient crystalline rocks which forms a hilly upland. Above the hilly upland in a few places appear the stumps of old worn-down mountains with a massive rounded appearance similar to that of parts of the southern Appalachians of the United States. The crystalline bases, especially in the interior, have a cover of stratified rocks which has formed table-like plateaus with steeply scarped margins.

In the Guiana Highlands, lying between the Orinoco and Amazon rivers in Venezuela, the Guianas, and Brazil, the granites and gneisses of the crystalline hilly upland have weathered deeply, producing a thick mantle of fine-grained soils and gently rounded hills. Above the hilly upland in French and Dutch Guiana and along the border of Brazil rise low mountains with steep sides and rounded tops. The most continuous group of such mountains is the Tumucumaque Range, some 3,000 ft. in elevation, which forms the drainage divide between Brazil and French and Dutch Guiana. The stratified sandstones are much more resistant than the granites in the rainy tropics and stand distinctly above the general level of the crystallines with margins marked by steep cliffs. The sandstone plateaus are found in the west, particularly in Venezuela. The highest elevation of the Guiana Highlands is Mount Roraima, with an elevation of 9,219 ft., which is not a mountain at all, but a flat-topped plateau bounded by steeply cliffed sides. Magnificent waterfalls occur where the rivers rising on the sandstone plateaus of western British Guiana fall over the scarped sides.

The same elements appear in the much more extensive Brazilian Highlands. In most of eastern Brazil the base of crystalline rocks is exposed in a surface of rounded, gentle slopes. Scattered over these uplands are many low knobs, groups of hills, and ranges of low mountains composed of quartzites and other types of crystalline rock more resistant than the granites and gneisses. The highest point in Brazil is the Pico da Bandeira, 9,386 ft., on the border between the states of Minas Gerais and Espírito Santo. Relatively high ranges of mountains are the Serra dos Orgãos, northeast of Guanabara Bay, and the Serra de Mantiqueira, on the southeastern border of Minas Gerais. Lower, but significant for its mineral deposits, is the Serra do Espinhaço in the state of Minas Gerais. In northeastern Brazil the highlands rise gradually from the Atlantic coast to the interior, but south of Salvador the coast is backed by a steep wall-like slope, the Great Escarpment, which rises to elevations of 2,600 ft. and more. Generally it is broken into a series of steps, forming parallel escarpments with deep valleys between. Along the coast in São Paulo state, in the section known as the Serra do Mar, the escarpment forms one unbroken slope from the edge of the upland to the sea. Most of the rivers which drain the Brazilian Highlands have their sources in the central and southeastern sections, some at the very edge of the Great Escarpment within sight of the Atlantic. They flow, however, westward or northwestward toward the interior, draining to the Atlantic by circuitous routes through the Paraná, São Francisco, or Amazon systems. Over large areas of inland Brazil the crystalline base disappears under a covering of stratified rocks in the form of table-like plateaus. In northeastern Brazil, the eastern limit of the main sandstone plateaus is a prominent cuesta which runs south-

ward from Parnaíba along the eastern boundary of the state of Piauí. In the stratified formations of southern Brazil and in patches elsewhere occur sheets of dark-colored lava known as diabase. The Paraná Plateau is one of the world's largest formations built of such accumulations of successive lava flows. The diabase is especially resistant to erosion, and the edges of the lava sheets stand out prominently in steep escarpments over which rivers plunge in great waterfalls, as at Iguaçu and Guaíra.

In dry Patagonia the granites and gneisses of the crystalline base are relatively resistant to the processes of erosion and stand out prominently as areas of hilly land surmounting the vast level-topped plateaus. The plateaus, formed of horizontal strata, some of sedimentary origin, some composed of flows of lava, rise like a series of gigantic steps toward the west where the highest tablelands are over 5,000 ft. above sea level.

**Harbors.** The South American coasts offer few good natural harbors. Most of the ports along the more than 2,000 mi. of Pacific coast of Peru and Chile are only partly protected by headlands, and ships must anchor well out beyond the heavy surf and load and discharge cargo by lighter. The largest indentation of the Pacific coast, outside the Chilean Archipelago, is the Gulf of Guayaquil. The port of Guayaquil, a few miles up the Guayas River from the gulf, is accessible to all but the largest vessels. In middle Chile a large crescent-shaped bay protected by a headland to the south made possible the development of Valparaiso as the principal Pacific port of South America. Along the tideless Caribbean coast, sand bars and rapid silting at river mouths necessitate constant dredging at such ports as Barranquilla and Maracaibo. Two of the best harbors on the Caribbean coast are Puerto Cabello and La Guaira, which is artificial, but both are backed by the abruptly rising mountains of the Venezuelan highlands. The northeast Atlantic coast is also marked by silting and sand bars. At Georgetown, British Guiana, the sand bar at the harbor entrance can be crossed only at high tide. Guanabara Bay, formed by a break in the Great Escarpment which allows the sea to come in, gives Rio de Janeiro one of the world's finest natural harbors, but the highland slopes which hem it in render access to the interior difficult and costly. The harbor at Buenos Aires is not natural; this port is maintained only by constant dredging of the low flats of the Plata. Along the desert coast of Patagonia, cliffs at the water's edge and the great tidal range make landing difficult. Only at Puerto Madryn, located on a deep gulf, and at Punta Arenas on the Strait of Magellan is it possible for ships to tie up at docks.

**Rivers.** South America's major navigable rivers have not contributed to the development of the continent as have those of eastern North America. The Amazon, though navigable for ocean-going steamers farther upstream than any other river in the world, traverses a region on which human efforts have so far failed to make much impression. The Orinoco likewise serves an area of very sparse population. The Paraguay-Paraná-La Plata system is marked by shallow waters, sand bars, and shifting channels, and only the lower portions up to Santa Fe are heavily used. The Magdalena, which for some 800 mi. is Colombia's chief artery of transportation, is characterized by a silting mouth, fluctuating water levels, shifting channels, and rapids which must be portaged. Falls and rapids make the rivers which drain the Brazilian Highlands useless for navigation, except for the São Francisco which is navigated with difficulty for hundreds of miles above the Paulo Afonso Falls, a series of three waterfalls which lie between Alagoas and Baía states.

## CLIMATE

Three-quarters of South America lies within the tropics, but, contrary to popular beliefs, all tropical climates are not unhealthful and all tropical climates are not alike. Tropical South America includes regions of such varied climatic conditions as the cool, cloudy desert of the Peruvian coast, the snow-capped peaks of the Andes, the hot and rainy Guiana

*AVERAGE ANNUAL RAINFALL*

coast, the dry Caribbean coast of Venezuela, and the highlands inland from Rio de Janeiro where winters are moderate in temperature and relatively dry. The effects of location in terms of latitude, or distance from the equator, are modified by such other major controls as ocean currents, the direction of prevailing winds, high and low pressure areas, size and shape of land masses, mountain barriers, and altitude.

**Pacific Coast.** Along the Pacific coast there is a succession from north to south of hot wet climate (Colombia and northern Ecuador), cool, often cloudy, desert (southern Ecuador, Peru, and northern Chile), a mediterranean climate of cool dry summers and mild wet winters (middle Chile), and a perpetually stormy, cool and rainy climate (southern Chile). Major factors are the warm waters of the Pacific Equatorial Counter Current off the coasts of Colombia and Ecuador, the cold Peru (Humboldt) Current which bathes the coast from about 30° S. lat. northward to the Gulf of Guayaquil, and the prevailing westerly winds, the roaring forties, which sweep the southern tip of the continent south of 40° S. lat.

**Eastern Coast.** Prevailing east and northeast trade winds blowing across the warm waters of the Caribbean and Atlantic coasts bring an abundant annual rainfall of 40 in. or more to most of eastern South America north of the mouth

of the Plata. Exceptions are the arid Caribbean strip of Venezuela and an area of irregular rainfall and frequent drought in northeast Brazil. Rainfall of over 80 in. a year is found along the Guiana coast, in the upper part of the Amazon Basin, in scattered spots along the Great Escarpment, and on some of the mountain summits of southern Brazil. Temperatures average above 80° F. in the warmest months along the Caribbean and Guiana coasts (August or September), in the Amazon Basin (August, September, October, or November), and in the Gran Chaco (December or January). The highest extreme temperatures in South America have been recorded along the Caribbean coast and in the Argentine Chaco rather than in areas close to the equator. In the Chaco the difference in temperature between the warmest and the coolest month is nearly 30°, the greatest in South America, while in regions closer to the equator there is little variation in temperature from month to month. It is this lack of any cool season and, in the Guianas and the Amazon Basin, the effects of high humidity which give the equatorial regions a reputation for intense heat. In actual fact, much greater extremes of hot weather are experienced in the North American corn belt during summer heat waves. In the interior of Brazil, inland from Rio de Janeiro and São Paulo, because of the higher altitude, climates are relatively cool, similar to those of the southern Appalachians of the United States.

Buenos Aires and the humid Pampas, located in a transition zone, have weather noted for its variability. Cloudy, warm, and depressing weather is brought by the *norte,* the sultry north wind, and clear, cool, dry weather is brought by the *pampero,* the invigorating wind which comes from the cool south across the Pampas. In general, Buenos Aires has about the same temperature in January, the Argentine summer, as does New York in July, while July temperatures in Buenos Aires are about the same as winter temperatures at Charleston, South Carolina. South of the latitude of Buenos Aires the shape of the continent, a relatively narrow finger projecting into the wide expanse of the southern ocean, is an important factor in temperature conditions. Temperatures are relatively mild, being much lower in summer and higher in winter than those associated with areas of the middle latitudes far distant from the moderating effect of the oceans. Even in Tierra del Fuego, more than 55° south of the equator, winters are not comparable in severity to those of Canada or the northern United States. Although temperatures in January, the warmest month, average below 50°, temperatures in June, the coldest month, average above 32°. Most of Patagonia is desert, the cold waters of the Falkland Islands Current reducing moisture from the Atlantic and the Andes acting as a rain barrier on the west.

P. E. J.

## SOILS

Perhaps less is known generally about the soils of South America than about those of the other continents. Most of them are tropical, except in the southern part. At the very southern tip is a bit of tundra. East of the high mountains in Argentina, there are broad areas of grassland soils, similar to those in North America and Asia. Most important are the nearly black, highly fertile chernozem and similar soils. Actually, in Argentina, many of these soils are sown for grazing, although they could be used more intensively for grains.

West of the mountains, the soils, for a long way each side of the equator, are very dry. A few are irrigated, and probably more could be. The northwest coastal strip contains a variety of tropical soils, some of which are suitable for the production of cacao and other plantation crops. Some of the most abundant food crops are produced from the associated alluvial soils.

Most of the agricultural development in Brazil is in the southern part of the country, on red-yellow podsolic soils somewhat like those in the southeastern United States. Such soils have more clay in the subsoil than in the surface, and are not highly productive when first cultivated; moreover, they are subject to erosion when unprotected by thick-growing vegetation. They can be built up to a high state of productivity, however. Besides these soils, there are others, developed from limestones and highly basic igneous rocks, that are naturally more productive and not so erosive.

The great Amazon Basin is largely unexplored, although a few soil scientists have seen parts of it. There are significant but undetermined areas of ground-water laterite, a very poor soil. Such soil develops on nearly level landscapes having alternating wet and dry seasons. Beneath the leached surface there is a mass of weathered clay that hardens to a slaglike rock upon exposure, or even, sometimes, following the cutting of the natural forest. But there are good soils in the Amazon Basin: alluvial soils along many of the streams, and soils on steep slopes that are continually rejuvenated through washing away of the leached surface and the incorporation of fresh minerals from beneath. Such soils are productive, but when they are placed under cultivation great care must be taken to prevent erosion through the use of terraces, or of nearly permanent mixed cultures.

Certainly there are many millions of acres of soil suitable for farming in South America, especially in the upper basin of the Amazon and in the central part of the continent, provided modern fertilizers and other techniques are used. But little actual study and mapping of the soils have been done, and much of the possible development must await the growth of transportation and industry.

Many casual observers of the luxuriant tropical forest are incorrectly persuaded that its soils are fertile. Sometimes they are. But often the nutrients of such soils are exhausted by a few crops, unless the soils are fertilized, or unless large amounts of compost are used. As in Africa and other tropical countries, many native farmers clear a few acres from the forest, grow a few crops, and then let the soil return again to the forest as they clear more land.

C. E. K.

## MINERAL RESOURCES

Most of the mineral wealth of the South American continent is contained within the rocks of either the Andes Mountains or the Brazilian Shield. The Guiana Highlands and the sedimentary basins along the Caribbean coast are additional districts with valuable minerals. Located between the Andes and the Brazilian Shield, the Argentine Plateau is as yet largely unexplored. South America is most prominent in the production of oil, bauxite, copper, lode tin, nitrate, vanadium, and quartz crystal.

**The Andes Mountains.** The province of the Andes, which extends from northern Colombia to the southern tip of the continent along its western border, consists of both igneous rocks, including recent volcanoes, and sedimentary rocks. Within the sedimentary rocks are occasional beds of coal, but neither the Andes nor South America generally can be considered as having adequate coal resources for domestic needs. On the other hand, the metalliferous deposits of the Andes include some of the great ore bodies of the world.

At the northern end of the province is Colombia. Within its borders are a number of coal fields which had not been extensively developed by 1950. The coal is of Cretaceous age;

some of it is coking coal. Colombia is the only South American country to produce platinum and emeralds.

Farther to the south is Peru. In its sedimentary rocks occur both coal and oil deposits in relatively minor amounts. Still producing copper, as well as lead in substantial quantity, the Cerro de Pasco mine high in the Andes was at one time one of the leading copper producers in the world. The greatest vanadium mine, the major source of the world's vanadium for many years, is at Minas Ragra in Peru at an elevation of 16,500 ft. Although South American mercury production has become negligible, the Huancavelica district was at one time an important source. Likewise in the early days of exploration and exploitation Peru was a major source of gold and silver.

That part of the Andean province located in Bolivia contains the largest known lode-tin deposits in the world. Occurring in a mineralized zone about 60 mi. wide and 500 mi. long, the tin ores are associated with tungsten, silver, and copper. Bolivia also has stood high in antimony production, and although individual deposits are small, it is believed a considerable reserve exists.

Chile is one of the leading coal producers of South America and has reserves estimated at 2,000,000,000 tons. It is most noted, however, for its enormous copper deposits located at Chuquicamata, Potrerillos, and Braden. At Chuquicamata, 90 mi. east of the coast, is perhaps the world's largest, with over 1,000,000,000 tons of known reserve. Chile is also the leading source of natural nitrate, which occurs in an impure rock known as caliche in the arid intermontane valley, the Atacama Desert, which lies between the coast range and the Andes. Volcanic sulphur, commercial exploitation of which began in 1935, is also abundant. Other mineral resources include some iron ore and manganese.

The eastern slope of the Andes in southern South America is in Argentina. Tungsten deposits are scattered along the belt for a considerable distance, and lead is produced in the Aquilar district in sufficient quantity to make Argentina self-sufficient in this metal. Zinc in substantial amounts is associated with the lead.

**Brazilian Shield.** The Brazilian Shield is a large area in eastern South America underlaid by rocks of Pre-Cambrian age. It is an upland and plateau country, separated from the Andes by the low-lying Argentine Plateau. During World War II the Brazilian Shield was of utmost importance as a source of quartz crystal used in the construction and operation of radio and allied detection devices. Another strategic mineral produced in quantity is sheet mica. Industrial diamonds have been mined in Brazil since the eighteenth century. Until the richer deposits of India were discovered, the Brazilian seashore sands supplied the world with monazite, the ore of thorium. There remains, however, a large reserve of raw material for atomic energy in the monazite sands of the Brazilian coast.

One of the largest deposits of high-grade iron ore known in the world is in Minas Gerais, Brazil. Although it contains an enormous quantity of 70-per-cent iron ore, there is no near-by coal supply for smelting, so that the ore has to be shipped abroad for conversion to metal. Minas Gerais also contains high-grade deposits of manganese ore, which is mined in considerable quantity at Ouro Preto. The reserves are plentiful. Manganese is exported from Brazil to the United States in increasing volume. In the southern part of São Paulo, Brazil, a number of deposits of silver-lead ore were discovered and developed during the early years of World War II.

**Guiana Highlands.** The Guiana Highlands are geologically similar to the Brazilian Shield, but are separated from it by the alluvial valley of the Amazon. The climate, warm and humid, causes more rapid weathering processes in the Guianas than in the more temperate Brazilian Shield, a fact which has produced enormous deposits of bauxite, the ore of aluminum, in Surinam and British Guiana. These deposits are the major source of raw material for aluminum manufacture in the United States and Canada.

**Sedimentary Basins Province.** This province is at the northern end of the continent adjacent to the Caribbean Sea. The basins contain a series of thick sedimentary rocks in which prolific amounts of oil have been discovered. At the epicenter of the Maracaibo Basin, covering western Venezuela and eastern Colombia, is Lake Maracaibo. What is perhaps the greatest aggregation of oil fields in the world, one that has been responsible since the late 1920's for Venezuela's rank as second or third among the world's oil-producing nations, is adjacent to the eastern shore of the lake. In eastern Venezuela is the Orinoco Delta, where a number of oil fields have been discovered, and beyond it is the British island of Trinidad, which produces both liquid petroleum and natural asphalt in abundance.

**Argentine Plateau.** This province includes the plains belt located between the Andes and the uplands of the Brazilian Shield. The large volume of sedimentary rocks present in this province is mostly unexplored. Southern Brazil has a small coal-mining industry in an area of Carboniferous rocks. The Argentine Pampas contains a number of relatively small oil fields, and additional fields occur in western Argentina in the Pampas-Andes border zone. The potentialities of oil production in the Chaco region of Paraguay, Bolivia, and Argentina were under exploration and initial development in 1950. K. K. L.

## FLORA

**General Characteristics.** South America, stretching over almost seventy degrees of latitude embracing steaming jungles and scorching deserts to regions of perpetual snow, is one of the richest and most complex botanical regions of the world. Its diversity in topography and climate is reflected in a corresponding multiplicity of vegetation types and in one of the richest of all floras. Many important economic plants come from this area, and the Inca Indians of the Andes were among the most active and successful of all peoples in bringing plants under cultivation.

The flora is incompletely known, but contains an enormous number of species. Tropical regions, in general, have far more numerous species than do temperate, and the greater part of South America is tropical. Since portions of it have been above water from geologically very ancient times, and since the degree of isolation has been extreme, endemism is marked and connections with other floristic regions are relatively slight. The principal relationship is with the floras of Central and North America, to the tropical floras of which it has contributed heavily, receiving certain elements, especially montane ones, in return. Relationship with the Antilles also is close, much of the flora of the latter being derived from South America. A small but very definite common element exists with the flora of western Africa, and the south Andean flora has close connections with that of Australasia.

Floristic regions of more than ordinary interest are the Pacaraima mountain system, between Brazil and Venezuela; the highlands of southeastern Brazil; the Amazonian lowlands; and the Andes. Local endemism is extreme in many areas, but the whole continent is so poorly explored botani-

cally that little of real significance can be said on this subject. A number of families are endemic to the continent, as the Nolanaceae, Malesherbiaceae, Brunniaceae, Brunelliaceae, Thurniaceae, Calyceraceae, Trigoniaceae, and Gomortegaceae. Many others have their principal development there. Some theories suggest South America as the place of origin of the seed plants. Fossil plants are known from various parts of the continent, but South American paleobotany is in its infancy.

**Floristic Regions.** Floristically the continent may be divided very roughly into about twelve regions. These overlap and grade into one another, are complex within themselves, and are difficult to define.

*Coast of Colombia and Ecuador.* The rainy region of the Pacific coasts of Colombia and Ecuador is really a continuation of the Central American rain forest. It also has much in common with the Amazonian rain forest.

*Caribbean Coast.* The dry north coast has a typical Caribbean flora, with thorny Leguminosae, *Bursera, Hura, Crescentia, Tabebuia,* Bombacaceae, and Cactaceae prominent.

*Orinoco Plains.* The plains (llanos) of the Orinoco drainage are grasslands, savannas, and tropical deciduous forest, with numerous grasses, sedges, Leguminosae, and Palmaceae such as *Mauritia* and *Copernicia.* The floristic relationships are primarily to the south.

*Andes.* The Andes, with their tremendous north and south extension, altitude, and topographic diversity, have a rich and complex flora with many highly endemic elements. There are many genera better known from the temperate zones of North America, such as *Lupinus, Castilleja,* and *Viola;* austral genera from the subantarctic regions, such as *Acaena, Gunnera,* and *Drimys;* and numerous derivatives of the surrounding lowland zones. Striking is the development of the Compositae, Campanulaceae, Rubiaceae (including *Cinchona,* source of quinine), Labiatae, Ericaceae, Rosaceae, Orchidaceae, Bromeliaceae, and Pteridophyta, as well as such endemic families as Malesherbiaceae, Brunelliaceae, and Gomortegaceae. An extension of this region may be the Patagonian-Fuegian steppe, of extreme southern South America, even though this is largely at lower altitudes.

*Pacaraima Region.* The poorly explored but fascinating Pacaraima region, a series of flat-topped sandstone mountains on the Brazilian-Venezuelan border, is small in area, but on these summits is an almost wholly endemic flora. This consists largely of archaic relicts of a former flora, the other principal present-day remnants of which are found in the mountains of southeastern Brazil. There is also some slight affinity with the floras of the Andes, the high mountains of the Oriente of Cuba, and the mountains of West Africa. Among the families with outstanding endemics are the Eriocaulaceae, Xyridaceae, Bromeliaceae, Cyperaceae, Ericaceae, Lentibulariaceae, Rubiaceae, etc.

*Amazonian Forest.* The vast forest of the Amazon Basin, though mostly occupying a relatively uniform and recent area, is complex and rich in species. Rubiaceae, Loganiaceae, Myrtaceae, Lecythidaceae, Ochnaceae, Euphorbiaceae, Lauraceae, Moraceae, Palmaceae, and Leguminosae are among the prominent families. The relationships are with the Pacific Coast-Central American and southeast Brazilian rain forest regions.

*Eastern Brazil.* Eastern Brazil is a complex region, mainly forested, but largely with different genera and species than in the surrounding areas, growing under completely different conditions. The northern part of this region is characterized by palm forests with species of *Orbignya, Copernicia, Mauritia, Euterpe,* etc. The caatinga zone is noted for its Cactaceae, as well as for Leguminosae and other families which lose their leaves in the dry season. Floristic relationships are with other dry regions of the continent, as well as with Amazonia and the forests to the southwest.

*Coast of Southeastern Brazil.* The wet coast of southeastern Brazil, the area of Rio de Janeiro, contains an unbelievably rich flora, characterized by numerous species of Rubiaceae, Bromeliaceae, Melastomaceae, Euphorbiaceae, Moraceae, and Myrtaceae. It has much in common with the Amazonian forest and with the west eastern slopes of the Andes.

*Highlands of Southeastern Brazil.* The highlands above and to the west of this coastal strip are characterized by an ancient flora with many Xyridaceae, Eriocaulaceae, Bromeliaceae, Velloziaceae, and Lentibulariaceae. Its closest connections are with the flora of the Pacaraima Mountains. There are also many elements from the surrounding regions.

*Paraná Basin and Argentine Plains.* The Paraná drainage and the Argentine plains are quite diversified in their flora, but form a logical floristic region. Gramineae, Cactaceae, Leguminosae, Anacardiaceae, and Rhamnaceae are prominent families. Here are found the economically important yerba maté (*Ilex paraguariensis*) and quebracho (*Schinopsis* and *Aspidosperma*), and in the northeast is the famous Paraná pine (*Araucaria angustifolia*). The floristic affinities are largely with semiarid and arid regions in more northerly parts of South America, but *Larrea divaricata, Koeberlinia spinosa,* and some other genera and even other species are common to this region and arid southwestern North America.

*Pacific Lowlands.* The desert strip along the western base of the Andes has a relatively small but highly specialized flora. Solanaceae, Nyctaginaceae, Bromeliaceae, Cactaceae, Compositae, Boraginaceae, Leguminosae, Rhamnaceae, Malvaceae, the endemic Nolanaceae, *Capparis,* and such strand plants as *Batis, Sesuvium,* and *Distichlis,* characterize the deserts, lomas, desert scrub, and salt flats of these Pacific lowlands. The relationships are with more northern and inland dry areas, with the tropical strand flora, and with arid southwestern North America.

*South Chilean Forests.* The Fuegian, Magellanic, or south Chilean forests, dominated by *Nothofagus* and southern hemisphere conifers, and forming the most isolated major forest region in the world, has its floristic connections with New Zealand and southern Australia, as well as with the Andes to the north.

**Principal Economic Species.** The forest flora of South America is rich in economic species. *Bertholletia excelsa* produces brazil nuts; *Anacardium occidentale,* cashews; *Theobroma cacao,* chocolate; *Hevea* and *Castilla,* rubber; *Swietenia,* mahogany; *Cinchona,* quinine; *Schinopsis* and *Aspidosperma,* quebracho; *Caesalpinia,* tara, divi-divi, and brazilwood; *Myroxylon,* Peru and tolu balsams; *Copernicia,* carnauba wax; and *Attalea* and *Leopoldinia,* piassava fiber, to mention but a few of the most conspicuous and important. Prominent domesticated plants that originated in South America are beans, pumpkins, squashes, tomatoes, potatoes, peanuts, sweet potatoes, pineapples, red peppers, tapioca, tobacco, barbasco, cacao, guarana, coca, Pará rubber, *Cinchona,* and probably maize. Of these, all but rubber and *Cinchona* were domesticated by the aborigines in prehistoric times. Important exotic plants in South America are coffee, sugar cane, African oil palm, coconut, molasses grass (*Melinis*), other forage and soil-protecting grasses, *Eucalyptus,* wheat, barley, and numerous and varied types of garden vegetables.

**Classification.** The vegetation of South America is complex and often difficult to classify. Much of it falls readily into the three commonly recognized major groups, forest, grassland, and desert, but many intermediate types exist, as well as some which do not fit well into any of them. Such is the type dominated by huge cushion plants in the Andes. Only with difficulty can the Colombian páramo be considered grassland. The *cerradão* of eastern Brazil is not easily placed; it is generally considered a savanna, since it is intermediate between grassland and forest, but it is strikingly different from other savannas.

**Forests.** *Rain Forest.* The forests are of many types. Basic is the tropical rain forest, which occupies enormous areas in the Amazon Basin, the coastal strip of southeastern Brazil, the Guianas, the upper southern tributaries of the Orinoco, the eastern slopes of the central and northern Andes, the middle Magdalena Valley, the Atrato Valley, and the Pacific slopes and lowlands of Colombia and Ecuador. It varies greatly from place to place, ranging from the tall lowland type, with a dense canopy filled with vines, clean tall trunks, and little undergrowth, to montane rain forest on high slopes, with lower stature, great quantities of bryophytes, ferns, orchids, and other plants as epiphytes, and an almost impassible undergrowth. The former type grows either on sterile soils which accumulate little or no humus, or on low flood plains which are under water a part of the year. The montane type usually has a rich humus layer. In the northern Andes the rain forest extends to very great altitudes in places, assuming, of course, a temperate character. Some forests of *Polylepis* and *Gynoxys* reach elevations of 12,000 ft. or more in Colombia and Ecuador.

*Subantarctic Beech Forest.* In southern Chile and around the Strait of Magellan is the *Nothofagus,* or subantarctic beech forest, a temperate rain forest. In its northern portions various Southern Hemisphere conifers and podocarps constitute a large part of it. It is an evergreen forest occurring generally at middle and low altitudes on the rainy west coast, in the belt of the prevailing westerly winds. The position of this forest corresponds to that of the dense wet evergreen forests stretching from Oregon to Alaska in the Northern Hemisphere.

*Palm Forest.* Palm forests are found in various regions, covering small or even extensive areas. The species of palms vary greatly in different regions. Best known and most extensive in area are the forests of *Orbignya, Copernicia, Mauritia,* and *Euterpe* in eastern Brazil. The Andean wax palm (*Ceroxylon*) forms forests in certain high valleys in Colombia. In some areas, as in the Chaco of Paraguay, palms occur in thin stands in grasslands, termed palm savannas.

*Tropical Deciduous Forest.* Tropical deciduous or rainy-green forests, similar to the monsoon forests of the Old World tropics, are found in widely scattered parts of the continent. They are usually in places that are transitional between rain forests, on one hand, and savannas and deserts, on the other. They are characterized by various Leguminosae, Bombacaceae, Meliaceae, Bignoniaceae, and other families that tend to lose their leaves in the dry season. There are usually various epiphytic Bromeliaceae and numerous vines, the latter also deciduous in the dry season. The weird, thickened, and often bottle-shaped trunks of some of the Bombacaceae give this type of forest a picturesque appearance. There are extensive areas of this type in the Chaco of northern Argentina, Paraguay, and Bolivia, and farther north in the Bolivian lowlands and western Brazil, in the caatinga of eastern Brazil, in the valleys of the west slopes of the Andes in Peru, in the deeper inner valleys of the Andes from Peru to Colombia and Venezuela, in the coastal hills west of Guayaquil, Ecuador, in the upper and lower Magdalena Valley of Colombia, along the Caribbean coast, and in the northern and southern parts of the Orinoco Valley plains. Along the Caribbean coasts, in eastern Brazil, and in coastal southern Ecuador, thorny legumes, cacti, and other thorny or spiny plants dominate this type of forest. Wooded tracts in these areas are termed thorn forests.

*Paraná Pine Forest.* In southern Brazil are extensive forests dominated by a picturesque and economically important timber tree, the Paraná pine (*Araucaria angustifolia*). These forests have been so exploited for timber that they are now much more restricted.

**Savannas.** Savanna is a term usually applied in phytogeography to a transition between forest and grassland in the form of open grassy country with scattered trees and patches of forest. The term park land is sometimes applied to it. Being thus transitional, it is an extremely variable formation. Areas corresponding to savannas are found in the plains of the Orinoco, where the term was originally applied; in scattered patches north of the Amazon; in large sections of the campos of south central and southwestern Brazil, especially in the Mato Grosso; in the Chaco; in northern and central Argentina; and in Uruguay. In the last it is intermingled with large sections of pure grassland. There is little doubt that in many or most regions the savanna is the result of fire and is maintained by both fire and grazing.

**Grasslands.** True grasslands of a prairie type, known as the Pampas, occur principally in the La Plata region of Uruguay and Argentina, and just to the south of that area. The Pampas are rich plains of loess soil, dominated by tall grasses, and are the basis of most of Argentina's wealth. They are ideal agricultural land. Consequently there are almost no stands of this vegetation in its original state.

The meadows above the timber line in the Andes, especially in Peru and parts of Bolivia, including the famous two-mile-high Altiplano around Lake Titicaca, also form extensive grasslands. In the south, from central Peru to central Chile, the *puna* type is a dry steppe, dominated by several harsh xerophyllous species of *Stipa,* while in northern Peru and Ecuador the *jalca* type is much wetter and has a more varied flora. Cushion plants of various sorts are dominant locally in all of these high regions. In northern Ecuador, Colombia, and Venezuela the meadows are dominated by the fantastic frailejon (*Espeletia*), a genus of the Compositae with large, conspicuously woolly leaves in great rosettes, either acaulescent or on erect postlike stems. These meadows are termed páramos, and are the home of a rich endemic flora with many gorgeous flowers. In the páramos of the Sierra Nevada de Santa Marta and of the Venezuelan Andes are found vegetable sheep (*Rauliopsis*), another composite genus, so woolly that the clumps of plants resemble small sheep. Vegetable sheep are otherwise known only in New Zealand. The different characters of these three types of mountain meadows seem to be correlated with the fact that they become dryer to the south.

**Desert Vegetation.** The Patagonian-Fuegian Steppe, in many respects, is an extension of the high altitude vegetation of the Andes, covering the southern extremity of South America east of the *Nothofagus* forests, even down to the low plains. It is a dry, cold, treeless desert, dominated by harsh grasses, rosette plants and cushion plants. Because of the extreme southern latitudes, somewhat the same condi-

tions prevail as at higher altitudes farther north. The area is also mostly in the rain shadow of the Andes.

North of this, from the east slopes of the Andes to the Atlantic coast of Argentina and the savanna west of the Pampas, extending north to the Chaco, is an extensive desert scrub formation. It is in the rain shadow of the Andes in the horse latitudes and the northern part of the prevailing westerlies belt. This vegetation, known as *monte occidental,* is a sparse xerophyllous type, with shrubs or low trees widely spaced. The creosote bush (*Larrea divaricata*), also dominant in the North American desert scrub, is common or dominant here.

Another type of scrub is the *tola* heath of the Altiplano of Bolivia and southern Peru. It is practically a pure stand of the genus *Lepidophyllum.* Other dry rocky areas in and around the Altiplano are dominated by huge woody species of the curious cushion plant, genus *Azorella,* called *llareta* or *yareta* locally. Both *tola* and *yareta* are important local fuels because of their high resin content and the absence of other combustible materials.

The narrow strip between the Andes and the Pacific, from north central Chile to the northern border of Peru, including the famous Atacama Desert and the Chilean nitrate beds, is one of the most extreme deserts in the world. Great areas are completely devoid of vegetation. Other areas have a low gray covering of several extremely xerophytic *Tillandsia* species. At the mouths of deep valleys emerging from the Andes are strips of vegetation running to the sea, supported by underground water draining from the mountains. Here are *Prosopis, Vallesia,* and *Tessaria,* as well as *Distichlis* and other grasses. Most of these areas are under irrigation and are Peru's most productive agricultural lands. In this desert the coastal hills, when bathed by periods of heavy fog or after the rare rains, sometimes many years apart, produce the remarkable loma vegetation. During a foggy season or after a rain, a covering of herbs appears, consisting of ephemeral annuals and tuberous rooted perennials, where before there had been nothing but bare ground. Many bright colored flowers, especially of the endemic family Nolanaceae, are found here. The lomas in central and southern Peru, as well as those around 26° S. lat. in Chile, are more dependent on fog, and develop more frequently, while those in northern Chile and northern Peru depend on rain and very rarely produce vegetation. Other large areas in this region have a very sparse scattering of *Prosopis,* cacti, and tree *Capparis.* The last is especially common in sandy places, where it acts as a dune binder. Toward the coast, in saline areas, are *Distichlis, Grabowskia, Baccharis,* and in the north the endemic *Cryptocarpus.* Immediately adjacent to the coast such strand succulents as *Batis* and *Sesuvium* have assumed dominance in places. Judging from the archeological remains, terraces, canals, fortifications, and so on, the land in this region under irrigation and human occupation in the time of the Incas and pre-Incas was much more extensive than now. This whole desert is the result of the proximity of the cold Peru Current off the coast. The current cools the sea air, which constantly flows toward the warmer coastal plain, bringing no available water with it for the lowlands and the lower western Andean slopes.

**Mangrove Formations.** The only other major vegetation type is the mangrove formation. This consists of a number of genera of trees especially adapted to growing in salt-water mud flats and estuaries. Many are equipped with extensive systems of prop roots, others with pheumatophores, apparatus for aerating the roots, which are usually submerged in still water. This formation occurs wherever there are extensive estuaries, a low or sinking coastline, or tidal flats in the tropical part of the continent, and is frequent from Ecuador to Panama on the Pacific side, and along the Caribbean and down the Atlantic coast to southern Brazil. F. R. F.

## FAUNA

**Origins and Relationships.** From the standpoint of zoogeography, South America forms the greater part of the Neotropical region, which includes, in addition, Central America, the West Indies, the lowlands of Mexico extending into Texas, and the coastal strip of Florida. Most of the South American fauna is of indigenous origin, but there is an important element which has descended from North American immigrants. There also are many interesting relationships between the faunas of the Neotropical, Ethiopian, and Australasian regions. These involve common fauna which are not extant in the northern continents, and about which varying theories of origin have arisen. On one hand, numerous land bridges have been visualized to account for their migrations from one region to another; on the other, they have given rise to the thesis that the cradle of mammalian life, at least, was in the northern continents, whence the primitive and usually less successfully specialized groups were pushed slowly into the southern continents as new waves of more aggressive and successful mammals appeared.

**Mammals.** The marsupials, characteristic of Australasia, are more abundant in South America than in the only other continent where they occur, North America. There are two families, the Didelphidae and the Caenolestidae. Of the didelphids, or opossums, there are at least three genera containing sixteen or seventeen species. The second family, the surviving remnant of a once very extensive and widespread group, is represented by *Caenolestes,* found in Ecuador, Colombia, and Peru.

Although continental South America has no representatives of Insectivora, the shrew, *Blarina,* is found in Central America. In Cuba and Haiti are found two species of an especially noteworthy insectivore, *Solenodon,* the nearest relatives of which are the tenrecs, *Centetes,* of Madagascar.

Perhaps the greatest contrast between the faunas of North and South America is that afforded by the Primates. North America has no monkeys and has had none for ages past, whereas there is a great variety of them in the tropical forests of South America. Indeed, South America ranks second in the number of primate genera, Africa having twenty-five and the Neotropical region fourteen. The Neotropical primates are representative of two families, the Hapalidae, or marmosets, and the Cebidae. The marmosets are the smallest of the monkey tribe and differ from all other monkeys in several features. The most conspicuous are the long claws on the feet and the nonopposable thumbs. The second family, the Cebidae, consists of the spider monkeys which, while superficially resembling those of the Old World, are very different in detail and are readily distinguished from them by their prehensile tails. In this family are the spider monkey, *Ateles;* the capuchin monkey, *Cebus;* the red howler, *Mycetes;* the saki, *Pithecia;* and the douroucolis, *Nyctipithecus.*

Just as Africa is a major center of insectivorous adaptive radiation, South America is one of the most important centers of rodent diversification. It is the center of the porcupine group, *Hystricomorpha,* of which there are at least twenty-nine indigenous genera. This variety of porcupines is in striking contrast to the sole North American representative, the Canadian porcupine, *Erethizon.* Among the many interesting hystricomorphic rodents are two genera of arboreal

porcupines which have long, prehensile tails: *Coendou* and *Chaetomys.* The coypu, *Myocastor,* is a large aquatic animal resembling the muskrat. The chinchillas (*Chinchilla* and *Lagidium*) of the Andes, the cavies (*Cavia*), and the Patagonian hare (*Dolichotis*) are typical South American hystricomorphs. The water hog, *Hydrochoerus,* an aquatic animal about the size of a pig, is the giant of the entire order Rodentia. Still another family of hystricomorphic rodents consists of the paca, *Cuniculus* and the agouti, *Dasyprocta.*

The remainder of the rodents in the Neotropical region are of northern origin and constitute a much smaller number of families and genera than in North America. There are very few species of rabbits; one is found in Brazil, and another in Costa Rica. True arboreal squirrels are present, but there are no ground squirrels, i.e., chipmunks, marmots, prairie dogs, and beavers. There is only one family of mice. The Carnivora are especially well represented in South America. The Felidae are represented extensively by the jaguar, *Felis onca,* which ranges from Central America into southern South America; the puma, *F. concolor,* occurring from British Columbia southward almost to Cape Horn; and the ocelot, *F. pardalis,* which is plentiful in the tropical regions of South America.

There are no true wolves or foxes in the region, but there are several species of canids not found elsewhere: *Icticyon venaticus, Canis microtus,* and *Cerdocyon thous.*

The weasel family is represented by two skunks, *Conepatus* and *Spilogale;* the grison, *Galictis;* the tayra, *Tayra;* and several species of otters, *Lutra.* The raccoons are especially well represented in South America. Typical members of the family are the coati, *Nasua,* and the kinkajou, *Cercoleptes.*

South America has only one genus of bears. This is the spectacled bear, *Tremarctos,* of the highlands of Peru and Chile. The only living perissodactyls of the Western Hemisphere are the tapirs, *Tapirus,* which are widely distributed throughout the warmer regions of South America.

Although their numbers are small when compared with the Old World, the artiodactyls are well represented. The peccaries, *Dicotyles,* range from Texas through Central America to Paraguay. Outstanding among the South American artiodactyls are the members of the camel family. Neotropical forms are the llama, *Lama glama;* the alpaca, *Lama pacos;* the guanaco, *guanacus;* and the vicuña, *Lama vicunna.*

True ruminants are represented in the Neotropical region only by deer, of which there are several genera shared with North America. The Virginia deer, *Odocoileus,* of the northern United States, extends through Mexico and Central America to Guiana and Peru. Peculiarly Neotropical are the diminutive brockets, *Mazama,* which seldom exceed two feet in height and have simple spikelike antlers not more than three inches long. The Chilean pudu, *Pudu,* is the smallest of all deer.

With the exception of one armadillo which has invaded Texas the Xenarthrous edentates are entirely confined to the Neotropical region. The armadillos are represented by three genera, *Priodon, Lysurius,* and *Chlamydophorus.* Included among the South American edentates are the ant bears, *Myrmecophaga;* the diminutive anteater, *Tamandua;* and the sloths, *Bradypus.* Both the sloths and the anteaters are forest animals, and are tropical or subtropical in distribution.

**Birds.** The Neotropical avifauna includes, as in all other southern zoogeographical regions, a representative of the ratites, the rhea, *Rhea.* Among the gallinaceous birds, South America has the curassows, *Crax,* and the guans, which are closely related to the brush turkeys of the Australasian region. The hoatzin, *Opisthocomos,* somewhat resembles the guans, but has some features that appear to associate it with the rail and cuckoos. Although the storks are, in general, confined to the Palaearctic and Oriental regions, there is one representative of the group in South America, the jabiru, *Ciconia.*

Closely allied to the ducks are the South American screamers, which form only one family and an order, Palamedeae, in themselves. The Derbian screamer, *Chauna chavaria,* is one of the best known species. There are several outstanding Neotropical swans, *Cygnus,* including the black-necked and the coscoroba swans.

Probably the most characteristic South American bird is the condor, *Sarcorhamphus,* of the Andes. This huge turkey vulture is the largest of the flying birds. Another characteristic member of the Cathartidae is the black turkey vulture, *Catharistes,* which ranges through Central America. Another of the Neotropical birds of prey is the huge and fierce harpy eagle, *Harpia harpyja,* of Central and South America.

The hummingbirds, although restricted to the New World, are not confined to the tropical regions, but the majority of the approximately five hundred species are natives of Central and South America. Some may be seen on the wing in snowy weather in Tierra del Fuego, and some frequent the vicinity of perpetual snow in the Andes of Ecuador at a height of at least 16,000 ft. The largest species, *Patagona gigas,* the giant humming bird, is nine inches long, while the smallest scarcely exceed a bumblebee in size.

Although the parrots evidently originated in the Australasian region, where they are one of the predominent elements of the avifauna, South America is credited with having some of the most advanced genera. The Neotropical macaws, *Ara,* are the most showy and gaudily colored of the entire parrot tribe. Rivaling the macaws in coloration is the quetzal, *Pharomacrus,* the national symbol of Guatemala. The brilliantly colored toucan, *Ramphastos,* is another typical Neotropical form. The Neotropical chatterers include the umbrella bird, *Cephalopterus;* the companero, *Chasmorhyncus;* and the cock of the rock, *Rupicola.* Closely related to the chatterers are the manakins, Pipridae, and the plant cutters.

**Reptiles.** Outstanding among the reptiles of South America are the crocodiles, *Crocodilus,* of Central and South America. The caymans, *Caiman,* close relatives of the alligator, are numerous in the rivers of the tropical regions.

The turtles are represented by members of the following families: Chelydridae, Dermatemyidae, Emydidae, and Testudinidae. The trionychid turtles, which are well represented in Holarctica, Ethiopia, and Australasia, are entirely absent from the Neotropical region. Lizards in the Neotropical region include amphisbaenids, anguids, and iguanids. Among the latter are the basilisk, *Basiliscus,* and the common iguana, *Iguana.* Snakes characteristic of South America include the bushmaster, *Lachesis mutus;* the fer-de-lance, *Bothrops atrox;* and the largest of all snakes, the anaconda, *Eunectes murinus.*

**Amphibians.** The amphibian fauna of South America is quite small, with only a few families represented. Except for three Amblystomas in Mexico, the plethodontid genus, *Oedipus,* includes all of the thirty or more Neotropical urodeles. Two genera of aglossal frogs, *Pipa* and *Protopipa,* inhabit the Amazonian and northern parts of South America. Their closest relatives, *Xenopus,* are found in Africa. *Eleutherodactylus* and *Leptodactylus* are typical of the bufonids in the Neotropics. Toads of the family Brachycephalidae are confined to South America. The tree frogs are typically New World forms and are widespread in South America, being

represented by the marsupial frogs, Hemiphractinae, and such genera as *Hyla, Gastrotheca,* and *Phyllomedusa.*

**Fishes.** South America is among the richest of the zoogeographic regions in the abundant variety of fresh-water fishes, ranging from the minute characins to the giant osteoglossid, *Arapaima.* Closely related to the African lungfish is the South American form, *Lepidosiren.* The largest portion of the fish fauna is composed of fishes of the order Ostariophysi. There are eleven families of catfishes. The most widely distributed family of the order is the Characinidae, many specimens of which are found in the aquaria of North American fish fanciers. The family includes both carnivorous and herbivorous forms and is represented by such genera as the cannibal fish *Serrasalmo; Curimatus;* and the fresh-water flying fish, *Gasteropelecus.* Closely related to the characins and probably derived from them are the electric eels, Gymnotidae, which are exclusively Neotropical in distribution. The oviparous cyprinodonts range southward from North America to Argentina. Another highly characteristic group of South American fishes is that of the numerous cichlids.

From the point of view of zoogeography, the Neotropical fishes are of great interest. The characins, cichlids, and nandids are shared with the Ethiopian region; the cichlids are shared with the Oriental region; and the lungfishes are shared with the Ethiopian and Australasian regions.

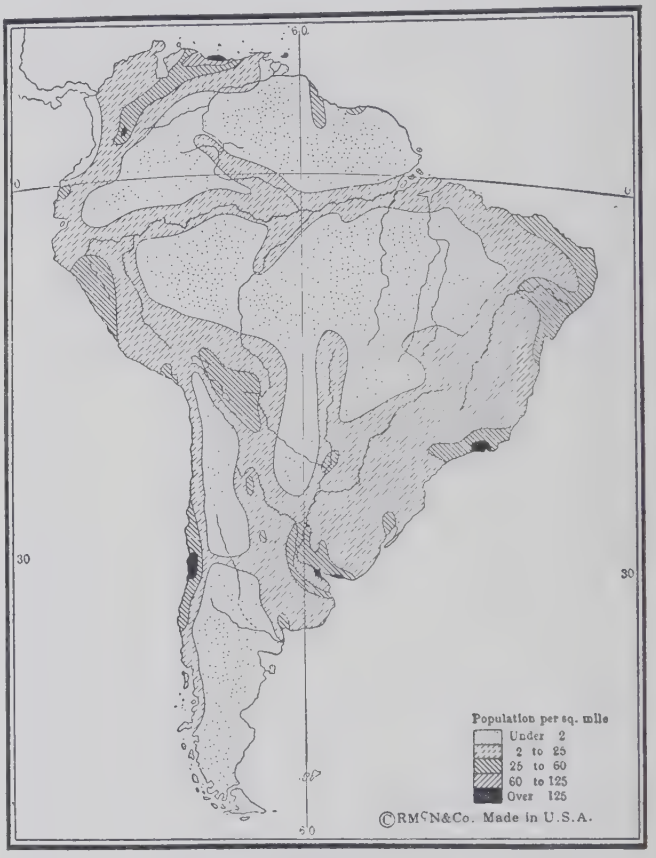
G. M. C.

## POPULATION

**Over-all Statistics.** The population of continental South America is approximately 103,373,000. According to estimates made between 1945 and 1947, the countries of South America have the following populations: Brazil, 50,700,000; Argentina, 16,104,929; Colombia, 10,544,670; Peru, 7,991,777; Chile, 5,389,554; Venezuela, 4,299,638; Bolivia, 3,854,100; Ecuador, 3,241,311; Uruguay, 2,202,936; Paraguay, 1,182,877; and the Guianas, 614,040. The totals represent an arbitrary computation of the Indian population of certain remote regions.

**Distribution.** The greatest part of the population of South America is found along the margins of the continent, with extensive interior areas of sparse population. In a broad zone along the Atlantic from the state of Rio Grande do Norte in Brazil to the humid Pampas of Argentina are located the three cities of the continent which have more than a million population, Rio de Janeiro, São Paulo, and Buenos Aires, as well as eleven of the other seventeen cities of the continent which have populations of over a quarter million. In western South America the greatest concentrations of population are in the high basins and valleys of the Colombian and Ecuadorian Andes, in the scattered coastal oases and Andean valleys of Peru, on the Bolivian Altiplano, and in the Central Valley of Chile. Even within these areas of population concentration, the pattern is one cluster separated by scantily settled territory, with only limited contact possible between the individual settled areas. The Antioquia region around Medellín, Colombia, the Central Valley of Chile, and the three southern states of Brazil are the only areas of concentrated population which show a marked expansion of their frontiers. In other areas pioneer settlements are remote from older settled areas and in many of them the settlers are new European immigrants. The vast virtually uninhabited regions of the continent—the Amazon Basin, western interior Brazil (the *Sertão*), the Gran Chaco, the eastern border valleys of the Andes, and Patagonia—have prompted much speculation on the possibilities of settlement by people from the overpopulated areas of the world. Even in the parts of these regions with the best climate and soils, however, isolation and the physical difficulties of transportation are significant limiting factors.

**Racial Groups.** The predominant racial composition of the population differs notably from one region to another. The three main elements are the Indian, the original inhabitant of the continent, the European, whether descended from the early Spanish and Portuguese colonial group or a more recent immigrant, and the Negro, originally imported as a



*POPULATION DENSITY*

laborer. Race mixture has gone on with little restriction or taboo, so that a very large proportion of South Americans are of mixed ancestry. The mestizo, the mixture of Indian and European, is the most commonly found racial type. In the Andean highlands of Ecuador, Peru, and Bolivia the dominant element of the population consists of Indians of the Quechua and Aymará linguistic groups. The Guiana Highlands, the upper Amazon Basin, and the more isolated parts of the Brazilian Highlands are occupied by widely scattered groups of more primitive Indians. During the nineteenth and twentieth centuries new immigrants from a number of European countries came to the previously sparsely settled southern and southeastern parts of South America. The considerable population of São Paulo, the three southern states of Brazil, southern Uruguay, and the humid Pampas of Argentina is largely of recent European origin: Italians, Spaniards, Portuguese, Germans, Poles, and lesser numbers of many other European nationalities. In Brazil, Negroes and mulattoes are numerous, particularly along the coast between Recife and Salvador. Negroes are dominant in the Pacific and Caribbean coastal regions of Colombia.

**Language.** The official language of Brazil is Portuguese and of the other republics, Spanish. In many areas Indian

languages are more common than the official language. In Peru, for instance, 50 per cent of the population speaks either Quechua or Aymará, and of these many do not speak any Spanish. P. E. J.

**SOUTH AMERICAN INDIANS.** *See* INDIAN TRIBES, SOUTH AMERICAN.

**SOUTHAMPTON,** one of Great Britain's leading seaports, a municipal, county, and parliamentary borough, located in Hampshire, in southern England, about 70 mi. southwest of London. The port lies at the head of the estuary Southampton Water, on a peninsula bordered on one side by the Test River and on the other by the Itchen River. The sheltered port, which is accessible to the largest ships afloat, has practically silt-free deep waters. In addition, the harbor is favored by double tides. Southampton is an important cargo port, but it is most famous as Britain's leading overseas passenger terminal with passenger ships from the world over docking at its piers. The discovery of Roman relics in the area attests to Roman settlements on the site, and there is evidence that the community has always been a port. The Norman kings moored their ships in the roads, and during the Middle Ages the port was controlled by the guild merchants, who carried on extensive trade with the Continent and the Orient. It was from Southampton that the Pilgrims in 1620 embarked on the *Mayflower* for the New World. Southampton, which had received its first town charter from Henry II in 1154 and had begun to send two members to Parliament in 1295, was granted a city charter by Charles I in 1640. Its real significance as a port dates from 1803 with the construction of a pier which became the foundation of the modern dock installations. The opening of the railroad to London in 1840 added impetus to the port's development, and by 1892 the docks covered more than 500 acres, an area which was to be subsequently trebled by the reclamation of tidal reaches and extensive dredging. The King George V Dock, which was the world's largest graving dock when it was opened in 1933, has a length of 1,200 ft., a width of 135 ft., and a depth of 50½ ft. During World War II the city was subjected to severe bombing raids, and approximately half of the city's buildings and many of the historic landmarks were either damaged or destroyed. In addition to shipbuilding and shipping, the city's chief industries include the manufacture of airplanes; the British Spitfire planes were first built at Southampton. The Royal Air Force maintains a seaplane base on an island in the channel, and there is a commercial airfield near the city. There is a large oil refinery in the suburb of Fawley and a small university, chartered in 1952, in the city itself. Southampton returns two members to Parliament. Pop. 1954, 175,500.

S. D. M.

**SOUTHAMPTON,** a village in southeastern New York, part of the township of the same name, situated 83 mi. east of New York City, on a narrow land strip, on the south shore of Long Island, between Peconic Bay and the Atlantic Ocean, facing the sea. The surrounding agricultural area is renowned for its potatoes. Founded in 1640, Southampton was incorporated as a village in 1894. For about two hundred years it was famous for its whaling activities, in which the Indians participated, and it was one of the chief trading ports of the Colonies. The village is famous as a fashionable summer resort and contains many estates. The old Hollyhocks House, built in 1662, and the Parrish Memorial Art Museum are features of the village. Near by is the Shinnecock Indian Reservation. Pop. 1950, 4,042.

**SOUTH AUSTRALIA,** a state in south central Australia with an area of 380,070 sq. mi., or 12.8 per cent of the total area of Australia. It is bounded on the north by Northern Territory, on the northeastern corner by Queensland, on the east by New South Wales and Victoria, on the south by the Indian Ocean, and on the west by Western Australia.

**Geographical Features.** *Topography.* Most of the state is under 2,000 ft. in elevation and relatively flat, with low tablelands in the northwest and shallow depressions such as Lake Eyre in the northeast. Lake Torrens and Lake Gairdner are the largest of several extensive bodies of water in the southeast. The only river of importance is the Murray in the extreme southeastern corner of the state, but artesian water underlies much of eastern South Australia. Not all of the state, however, is characterized by low plains or depressions with no outlet to the sea. In the northwest on the border with Northern Territory rise the Musgrave Ranges, highest point of which is Mount Woodroffe (4,970 ft.), and in the east the rugged Flinders Range dominates the surrounding lowlands. South Australia shares with Western Australia the Great Victoria Desert and Nullarbor Plain.

*Climate.* The northern half of the state is arid to semiarid with only 5 to 10 in. of rain a year, but the southern half, semiarid in the north, changes to humid in the southeast, where the average rainfall is over 50 in. annually at Mount Gambier, a town at the southeastern tip of the state. Erratic throughout the state, precipitation is least reliable in the north. While the northern rains come with the invasions of summer monsoons, those in the south are caused by cyclonic storms and fall in winter. Winter temperatures are moderate throughout, but summer temperatures are high nearly everywhere except on the southeastern coast.

*Forests and Soil.* Natural vegetation includes fairly dense eucalypt forests in the southeast, mallee or dwarf eucalypts along the Murray River and westward along the coast, open forests and park lands with grass and trees near Adelaide, and throughout most of the northern two thirds of the state desert and semidesert grasses, shrubs, and trees. There is little commercial timber. While there are some excellent soils in the vicinity of Adelaide and in patches along the Murray River, large areas have soils that are too stony, sandy, heavy, salty, or too poorly supplied with mineral nutrients or organic matter to be suitable for agriculture.

**Population.** The population of South Australia in 1947 was 646,216, with densities greater in the agricultural south, and much of the north either unoccupied or very thinly populated. Adelaide, with 382,604 inhabitants, or more than one-half the population of the state, is the capital and largest city. Port Adelaide (33,404) is the only other city over 7,000.

**Government.** *Administration.* The executive power of the state is vested in a governor, appointed by the British Crown, who is assisted by the Executive Council of 6 members. The legislative branch, Parliament, is divided into the Legislative Council of 20 members, half of whom are elected every three years, and the House of Assembly of 39 members, who serve three-year terms. The governor has no power to dissolve the Legislative Council.

*Political Parties.* In the elections of March 1950 there was little change in party representation in the House of Assembly, the Liberal Country League and the Independents gaining one seat each at the expense of the Labor Party. Totals were: Liberal Country League, 23; Labor, 12; and Independents, 4.

*Finance.* Revenue for 1948 totaled £18,843,000 and expenditures £19,156,000; the public debt was £118,852,000.

As in the other Australian states, the Commonwealth has been responsible since 1929 for state debts, contributing toward interest on the debt and the sinking fund set up for its redemption.

**Economic Resources and Activities.** Owing primarily to low rainfall, the occupied areas in the northern part of the state are suitable only for the light grazing of cattle and merino sheep, while the south coastal region and Murray River settlements have a more diversified economy based on agriculture, dairying, mining, and manufacturing. Almost any type of mediterranean or temperate fruit, grain, and vegetable can be grown in the better watered areas of the south and southeast. Dairying has developed in the vicinity of Adelaide and still more recently in the southeast. Dual purpose sheep, raised for both meat and wool, are pastured extensively in the wheat belt, and pig raising, poultry farming, and apiculture are important activities in favored localities. Mineral resources include low-grade bituminous coal, iron, pottery clays, salt, gypsum, copper, and lead, of which only iron has been mined extensively in the last decade. Manufacturing is concentrated in a few centers such as Adelaide, Port Adelaide, and Port Pirie.

**Social and Cultural Activities.** *Education.* Education in South Australia is compulsory and free up to 14 years of age. Primary, secondary, and technical public schools totaled 805 in 1946 and had 81,912 enrollees; besides several denominational schools, there were 155 private schools in 1947 with 21,936 students. In addition to technical and trades schools at higher levels, there are the University of Adelaide and a teachers' college.

*Social Services.* Benefits for disability, and old age and war pensions are paid by the Commonwealth, but there are several state provisions covering maternity, childhood endowment, widows, and the unemployed and sick.

R. G. B.

**History.** The early history of South Australia is closely associated with Edward Gibbon Wakefield's colonization theory, the essence of which was that land in a colony should be sold to settlers at a reasonable minimum price and the proceeds used to bring more colonists. Wakefield believed his system would produce a proper balance among land, labor, and capital within a colony.

The South Australian Land Company was founded in 1831 but could not persuade the Colonial Office to transfer the necessary land to a private company. Two years later the South Australia Association took up the problem and induced the imperial government to agree to the founding of a colony, which, however, was to be under governmental auspices. Land was to be sold for at least 12 shillings per acre and transportation of criminals was not to be permitted. Since the imperial government refused to provide financial aid a new South Australia Company was formed in 1834 by George Fife Angas for investment in the future of the colony.

Colonists arrived in 1836 and a settlement was made at what is now Adelaide. Because of the heavy expenditures required at first, the governor, George Gawler, drew drafts on the imperial government for public construction. Those who bought land sold it at a profit instead of putting it to productive use. The governor spent more than $1,000,000 (£291,000) above the revenue of the colony and a boom resulted. The imperial government decided not to honor the excess bills on the treasury and sent Captain George Grey to replace Gawler. After an investigation, the imperial Parliament in 1842 made South Australia a crown colony.

Grey, arriving in 1841, attacked with vigor the task of saving the new colony. His policy was one of forcing it to live within its means, and he persuaded the imperial government to honor the excess bills and thus enable the colony to make a new financial beginning. By 1842 he had put South Australia on its feet.

A parliamentary act of 1850 made possible the adoption of new forms of government in the Australian colonies. South Australia took advantage of the law and in 1853 prepared a new constitution which went into effect in 1856. The new government was bicameral, with the lower house being elected on a franchise, and the members of the existing Legislative Council being given life tenures in the new upper house carrying the same name. The system of responsible government was put into operation by common consent.

The absence of gold fields and the decision not to permit the transportation of convicts to the colony made a better-balanced economic life than that in New South Wales and Victoria. The gold rush in Victoria, moreover, acted as a stimulant to the production of grains and meat to supply the mining communities. By 1870 South Australian wheat had supplanted American wheat in the Australian market. Farmers in the colony gave considerable attention to harvesting equipment and soil fertilization. Successful breeding from the original flocks of merino sheep for arid conditions enabled pastoralists to compete with the concurrent development of agriculture.

South Australia for a time co-operated with the federal council set up in 1885. The Constitutional Convention of 1897 met in Adelaide, and South Australian voters gave a heavy majority to the proposed constitution in 1898 and 1899. In January 1901 South Australia joined the other Australian colonies in uniting to form the Commonwealth. In 1911 Northern Territory, formerly part of South Australia, was detached and made a separate territory. R. V. S.

**SOUTH BEND,** a city of central northern Indiana, the county seat of St. Joseph Co., situated on the St. Joseph River, 80 mi. southeast of Chicago. The name of the city is derived from its location on the south bend of the St. Joseph River. It was founded in 1831 by two rival fur traders, Alexis Coquillard and Lathrop Taylor, who became fast friends and worked together to lay out the town. South Bend was incorporated as a town in 1835 and as a city in 1865, and has the mayor-council form of government. Events of historical interest were the signing of important Indian treaties in 1679 and 1681 on the city's site. Historical sites of interest in the city and vicinity are the Council Oak, under which the Indian treaties were concluded; the Pierre Navarre Cabin, home of an early fur trader in the area; and the Northern Indiana Historical Museum. South Bend is the seat of the University of Notre Dame and St. Mary's College. Transportation is provided by the Grand Trunk, the Chicago, South Shore and South Bend, the New York Central, the Pennsylvania, and the New Jersey, Indiana and Illinois railroads, and by the American, the United, and the Trans World air lines. Highly diversified industries include in their output automobiles and truck and bus chassis; a wide range of products for airplanes, automobiles, ships, and radios; farm equipment; varnish; precision lathes; malleable-steel ranges; and sewing machines. Pop. 1950, 115,911.

**SOUTH BEVELAND.** *See* BEVELAND, SOUTH.

**SOUTH BOSTON,** a town in south central Virginia, situated in Halifax Co., about 65 mi. southeast of Roanoke, on the Dan River, in an agricultural area where tobacco, corn, and wheat are leading crops. The town is an important

tobacco market. South Boston, incorporated as a town in 1884, has the council-manager type of government. Transportation is provided by the Southern and the Norfolk and Western railroads. The chief local products include cotton, rayon, flour, condensed milk, and foundry products. Pop. 1950, 6,057.

**SOUTHBRIDGE,** a residential town in south central Massachusetts, situated in Worcester Co., on the Quinebaug River, 17 mi. southwest of Worcester, in an agricultural area devoted largely to dairying. Founded in 1730, Southbridge was incorporated as a town in 1816. The local government is by town meeting. A large proportion of the population is composed of French-Canadians. The privately financed Wells Museum contains a collection of Spanish, Central European, and early United States relics. The New York, New Haven and Hartford Railroad affords transportation. Local manufactures include worsteds, cutlery, and optical goods. Flood damage of over $20,000,000 occurred in August 1955. Pop. 1950, 16,748.

**SOUTH CAROLINA,** popularly known as the Palmetto State, one of the South Atlantic states of the United States. It is bounded on the north and northeast by North Carolina, on the southeast by the Atlantic Ocean, and on the southwest and west by Georgia, from which South Carolina is separated by the Savannah, Tugaloo, and Chattooga rivers. The area of the state is 31,055 sq. mi., of which about 750 sq. mi. are inland water. South Carolina, the smallest of the southern states, ranks thirty-ninth in size among the states of the Union.

South Carolina was one of the original thirteen colonies and was the eighth state to ratify the federal constitution; it entered the Union on May 23, 1788. The state motto is *Animis Opibusque Parati* ("Prepared in Mind and Resources"); another motto, *Dum Spiro Spero* ("While I Breathe, I Hope") also appears on the seal. The state tree is the palmetto; the state flower is the yellow jasmine; the state bird is the Carolina wren; and the state song is *Carolina,* music by Anne Curtis Burgess and words by Henry Timrod. South Carolina has forty-six counties; the state capital is Columbia.

## PHYSICAL FEATURES

**Topography.** South Carolina is made up of parts of three physiographic provinces which extend northwest to southeast across the state. The northwest belt, about 500 sq. mi. in area, lies within the Blue Ridge province. In this region are found the highest elevations as well as the greatest irregularity. Besides Sassafras Mountain (3,560 ft.), the highest elevation in the state, the Blue Ridge contains such peaks as Pinnacle Mountain (3,413 ft.); Hogback Mountain (3,226 ft.); Caesar's Head (3,218 ft.), and Table Rock (3,157 ft.).

The central belt of the state, about 10,500 sq. mi. in area, is a part of the Piedmont Upland province. The Piedmont has a rolling topography, its elevations ranging from 200 to 400 ft. along the southeastern border to 1,200 to 1,500 ft. at the base of the Blue Ridge.

The southeastern or coastal belt, about 20,000 sq. mi. in area, forming a part of the Atlantic Coastal Plain province, is low in elevation and comparatively level. The northern part of the coastline forms a great arc, made up for the most part of a fine sand beach broken by a few inlets such as Little River, Murrells, and North inlets. From Winyah Bay to the Savannah River the coastline is broken by bays, rivers, and inlets, many of which connect separate irregular areas of low elevation, such as the Sea Islands, from the mainland. The sea margins of the islands usually have firm sandy beaches. The larger bays and inlets, like those at Charleston, Georgetown, Port Royal, and Beaufort, form good harbors.

The materials which underlie the Blue Ridge and Piedmont provinces consist mainly of granites, gneisses, and schists, while the deposits of the Coastal Plain are mostly unconsolidated sands, clays, and marls. At the junction of the more resistant rocks of the Piedmont and the less resistant rocks of the Coastal Plain the streams have a series of falls or rapids, making the Fall Line, which marks the boundary between the two regions.

*THE SEAL OF THE STATE OF SOUTH CAROLINA*

*Hydrography.* Three river systems, namely, the Santee, the Pee Dee, and the Savannah, drain most of the state. These rivers and several smaller streams, including the Black, the Edisto, the Combahee, and the Coosawhatchie, which rise within the state, flow southeastward to the coast. In the upper and central parts of the state the streams flow swiftly through well-defined valleys and are important sources of water power, but below the Fall Line the streams become sluggish, flow through wide valleys, and are usually bordered by extensive swamps. The three largest lakes in the state—Lake Murray (about 53,760 acres in area), Lake Marion (about 96,000 acres), and Lake Moultrie (about 64,000 acres)—are artificial bodies of water constructed in connection with hydroelectric and navigation projects.

**Climate.** South Carolina has a humid subtropical type of climate, characterized by long summers and mild winters and by abundant rainfall distributed throughout the year. The mean annual temperature for the state as a whole is 63.0° F., varying between 45.5° in January and 79.8° in July. At Charleston, situated on the coast, the mean annual, January, and July temperatures are 67.1°, 49.9°, and 81.4° respectively, and at Greenville, in the upper Piedmont, they are 61.3°, 40.3°, and 76.9°. The maximum temperature on record in the state is 111° F. and the minimum is —13°. The average annual precipitation is 47.7 in., ranging from 61.3 in. in Oconee County to 45.5 in. in Barnwell County. The average frost-free season for the state is 229 days, ranging from 276 days at Charleston to 190 days at Caesar's Head. Snow is uncommon in the coastal section, and elsewhere it rarely remains on the ground long except in the Blue Ridge.

**Soil.** The parent materials from which the soils of South Carolina have been derived are crystalline rocks in the Piedmont and Blue Ridge, and sands, clay, and impure limestone in the Coastal Plain. Along the larger rivers there are belts of alluvial soils. Except for the limited areas of gray-brown podzolic soils of the Blue Ridge, the soils of South Carolina all belong to the red and yellow soils so extensively developed in the southeastern part of the United States.

EWING GALLOWAY

*Live oak avenue on a South Carolina plantation*

**Forests and Parks.** South Carolina has parts of three general forest regions. The Blue Ridge and Piedmont come within the southern hardwood forest, the upland areas of the Coastal Plain are in the southeastern pine forest, and along the river bottoms and in the swamps of the coastal region occur the river bottom forests. On the upper slopes of the Blue Ridge are found birch, beech, maple, and hemlock, the major part of the mountain area supporting a chestnut, oak, and yellow poplar forest interspersed with many other types of trees. The Piedmont forest cover is largely a mixture of short-leaf pine, oak, and hickory. The Coastal Plain, except for the river bottoms and swamps, has predominantly a long-leaf pine forest. In the river bottoms and swamps are found cypress, tupelo, gum, bay, water ash, willow, cottonwood, and water oak.

There are two national forests in the state, totaling in area 581,050 acres: the Sumter National Forest, located in the Piedmont and Blue Ridge sections, and the Francis Marion National Forest, located in Berkeley and Charleston counties. There are six state or county forests aggregating 148,618 acres.

**Flora.** Along the coast occur several species of palmettos and yuccas, the evergreen Carolina laurel cherry, the groundsel bush, the American olive, and other subtropical foliage. The river bottoms and swamps contain, in addition to the trees already described, such plants as honeysuckle, sweet bay, pitcher plants, Venus' flytrap, smilax, gallberry, loblolly bay, and the yellow jasmine, the state flower. In the higher sandy plains there are dogwood, trailing arbutus, sparkleberry, Spanish moss, and the pyxie, or flowering moss. The mountainous areas of the state are noted for their colorful displays of rhododendrons, azaleas, and kalmias.

*A limestone quarry in operation in Cherokee County, near the city of Gaffney, South Carolina*

AL SHARP FROM LILLER, NEAL & BATTLE

**Fauna.** The white-tailed deer is still common in the coastal areas, but the black bear and the wildcat are seldom encountered even in the upper wooded regions. Smaller mammals native to the state include oppossums, raccoons, otter, skunks, muskrats, shrews, red and gray foxes and squirrels, cottontail rabbits, marsh rabbits, rats, mice, moles, bats, weasels, minks, and woodchucks. Among the reptiles are six species of lizards, the alligator, and forty-three species of snakes, including four poisonous species: the water moccasin, the copperhead, the rattlesnake, and the coral snake. There are many species of turtles, salamanders, frogs, and toads. More than twenty varieties of edible fresh-water fish include the catfish, carp, wide-mouthed bass, crappie, bream, and warmouth. Among marine fish of commercial importance are the sturgeon, shad, menhaden, founder, sea bass, blue fish, hickory shad, sea trout, red drum, black drum, grunt, and king whiting. Oysters, crabs, clams, and shrimp are also taken in marketable quantities. The teeming bird life of the South Carolina coast includes the snake bird, the brown pelican, and innumerable ducks and shore birds, among the latter willets, terns, Wilson plovers, and oystercatchers. Egrets and herons abound in the swamps, and bobwhites, wild turkeys, doves, woodcocks, and Wilson snipe are plentiful in the plains and wooded areas. Among commoner birds of the interior are catbirds, orioles, mockingbirds, thrushes, sparrows, wrens, swallows, and vireos.

## ECONOMIC RESOURCES AND ACTIVITIES

**Minerals and Mining.** South Carolina has no appreciable coal or iron ore deposits; mining is a minor industry largely confined to mineral products such as kaolin clay, sand, crushed stone, vermiculite, and kayonite. No gold or silver is being mined in the state, nor is there any mining for precious stones. According to the 1950-1951 report of the state Department of Labor there are 33 mining operations in South Carolina, most of them sand pits and quarries; the value of the mineral output in 1951 was $12,145,944.

**Agriculture.** Despite the constant growth of manufacturing, farming remains the chief occupation of the inhabitants of the state. On Apr. 1, 1950, the 139,364 farms in the state comprised 11,878,793 acres, or 61.2 per cent of the total area, of which 5,385,990 acres were cropland, 2,190,638 acres, pasture land, and 5,561,854 acres, woodland. The farms averaged 85.2 acres and had a value of $69.06 per acre. The average value of land and buildings was $5,648 per farm. Total cash receipts in the state from crops in 1951 amounted to $396,442,000.

LEADING SOUTH CAROLINA CROPS

(1951)

| | *Acreage Harvested (1,000)* | *Production (1,000)* |

| Cotton lint | 1,045 | 871 bales |
| Cottonseed | 1,045 | 355 tons |
| Tobacco | 132 | 175,560 lb. |
| Corn | 1,316 | 26,320 bu. |
| Oats | 576 | 16,128 bu. |
| Wheat | 175 | 3,500 bu. |
| Peaches | ... | 4,330 bu. |
| Hay | 456 | 371 tons |
| Sweet potatoes | 28 | 2,380 bu. |

Truck farming is of importance, a great variety of vegetables being raised in commercial quantities.

*Animal Industry.* As of April 1950, there were 389,560

cattle on South Carolina farms, valued at $33,000,503; 598,076 hogs, valued at $7,843,118; 4,250 sheep, valued at $38,844; 23,331 horses, valued at $2,429,650; 146,522 mules, valued at $24,979,653; 3,550,985 chickens, valued at $3,748,304; and 56,871 turkeys, valued at $227,937. The total value of livestock, dairy products, and poultry and poultry products sold in 1949 was $40,018,391.

**Fisheries.** Ten hatcheries operated by the state game department produce bream, bass, and trout. Shrimping is the major fishing industry; raw shrimp caught in 1949 totaled 24,000,000 lb., valued at $5,000,000. Oysters, shad, menhaden, crabs, and clams are the most important species of marine life taken in commercial quantities in South Carolina waters.

**Water Power.** Installed generating capacity of electric plants in South Carolina on June 30, 1951 totaled 1,096,840 kw. of which 674,695 kw. comes from hydroelectric plants. The major hydroelectric plants are located at Pinopolis in Berkeley County and at Dreher Shoals in Lexington County.

**Manufacturing.** In 1951 there were 1,795 manufacturing establishments in the state, employing 193,396 persons who were paid a total of $455,941,569 in wages. The capital invested in all industries totaled $867,285,102, and the total value of all manufactured products was $2,230,507,920. Chief industrial areas are in Greenville, Spartanburg, Anderson, Columbia, Charleston, Lancaster, and Rock Hill.

LEADING SOUTH CAROLINA INDUSTRIES
(1951)

| | *Avg. No. of Persons Employed* | *Wages Earned in Year ($1,000)* | *Value Added by Manufacture ($1,000)* |
|---|---|---|---|
| Textiles | 130,838 | $346,102 | $1,608,985 |
| Paper and pulp | 3,811 | 12,562 | 110,638 |
| Clothing | 12,290 | 20,257 | 68,360 |
| Wood products and furniture | 8,973 | 16,204 | 63,868 |
| Fertilizer | 2,260 | 3,651 | 36,363 |

Other manufactures include chemicals and allied products, and stone, clay, and glass products.

**Transportation.** The first railroad operated by steam in the United States was the Charleston and Hamburg, chartered in 1827. By Jan. 1, 1830, this line had six miles of road ready for the "Best Friend," the first practical locomotive built in America. As of Dec. 31, 1950, there were 3,372 mi. of single or first main track of railway in the state. The Southern, the Atlantic Coast Line, the Seaboard Air Line, and the Charleston and Western Carolina are the main rail lines serving the state. In 1952 there were 49,330 mi. of highways in South Carolina, of which 23,138 mi. were in the state highway system; there were 8,889 mi. of primary road, and 14,249 mi. of secondary road. Of the total road mileage, 3,008 mi. have high-type pavement and 14,450 mi. have bituminous surface; the remaining 21,872 mi. have earth or soil-type surface. During the license year 1951-1952 a total of 649,742 motor vehicles were registered, of which 510,105 were passenger cars and taxis, 127,077 were trucks, 1,886 were commercial buses, and 3,366 were school buses. In 1952 there were 16 commercial and 37 mu-

nicipal airports plus some 25 or 30 private airstrips in the state. Delta, Southern, Eastern, and National air lines operate regularly scheduled routes within the state. The lower portions of the Savannah, the Edisto, the Santee-Cooper, and the Waccamaw rivers are used as navigable streams to a limited extent. The Intercoastal Waterway extends along the coast from the North Carolina line to the Savannah River. Charleston led all South Atlantic seaports in waterborne commerce during 1951 with port traffic totaling 4,614,909 tons; it led also in commerce to foreign countries and was only slightly exceeded by Savannah in imports.

**Communications.** In 1951 South Carolina had approximately 250,000 telephones in operation and 443,000 radio sets in 409,000 homes. There were 43 radio broadcasting stations in operation in 1952, and, although the state had no television stations, several are under construction for operation early in 1953. The state has 95 newspapers and 29 periodicals published in 89 towns. Sixteen of the newspapers are published daily (nine evening and six morning), two are tri-weekly, six are semi-weekly, and 71 are weekly papers. The Charlestown *News & Courier* and the *Post,* the Columbia *State,* and the Spartanburg *Herald & Journal* are among the leading newspapers of the state.

## GOVERNMENT AND POLITICS

**Constitution.** South Carolina is governed under a constitution established in 1895. An amendment to the constitution may be proposed in either house of the legislature, and if approved by two-thirds it must be submitted to the people at the next election held to choose members of the House of Representatives; then, if approved by a majority of those voting upon it and subsequently by a majority vote in each house of the General Assembly chosen at that election, the amendment becomes a part of the constitution. The constitution may be revised by a convention called by a two-thirds vote in each house and ratified by a majority of those voting for Representatives at the next election.

**Government Structure.** The chief executive is the governor, elected for a term of four years. The governor is ineligible to succeed himself. Other executive officers are the lieutenant governor, secretary of state, comptroller general, superintendent of education, commissioner of agriculture, adjutant general, treasurer, attorney general, and insurance commissioner.

The legislative body of South Carolina, known as the General Assembly, consists of a Senate, composed of one member from each of the forty-six counties, and a House of Representatives with one hundred twenty-four members from the counties in proportion to population. The Senators are elected for four years and the Representatives for two. The legislature meets annually at the state capitol in Columbia.

Judicial power is vested in a Supreme Court, made up of five judges elected by the legislature for terms of ten years, in two Circuit Courts, which comprise a court of common pleas, and in a Court of General Sessions.

**Finance and Banking.** General revenue and borrowings of the state of South Carolina, according to the *Compendium of State Government Finance in 1951,* published by the United States Department of Commerce, totaled $195,164,000 in that year, the general borrowings amounting to $27,550,000. The general revenue, totaling $167,614,000, included $103,790,000 in taxes and $33,673,000 in aid from other governments. The state tax revenue of $103,790,000 included $66,126,000 in sales, use, and gross receipts, $9,-

249,000 from license and privilege, $12,016,000 from individual income, $13,552,000 from corporation income, $1,512,000 from property, and $546,000 from death and gift sources. The sales, use, and gross receipts taxes, totaling $66,126,000 included $32,068,000 from motor fuels, $15,399,000 from alcoholic beverages, $8,097,000 from tobacco products, $2,799,000 from insurance companies, $3,136,000 from public utilities, $4,223,000 from soft drinks, and $404,000 from admissions and amusements. The license and privilege tax total, amounting to $9,249,000 included $5,381,000 from motor vehicles and operators, $539,000 from corporations in general, $757,000 from alcoholic beverages, $481,000 from hunting and fishing, $186,000 from chain stores, $215,000 from amusements, and $1,690,000 from occupations and miscellaneous sources.

General expenditure, according to the same source, totaled $166,612,000 in 1951 and included $7,133,000 for debt retirement, $49,382,000 for operation, $29,796,000 for capital outlay, $16,968,000 for assistance and subsidies, $2,225,000 for interest, and $8,492,000 for insurance benefits and payments. General expenditure for operation, capital outlay, and aid paid to local governments, totaling $159,479,000, included $36,977,000 for highways, $10,291,000 for health and hospitals, $56,064,000 for public education, and $16,899,000 for public welfare. The debt outstanding at the end of the fiscal year of 1951 was $119,143,000.

As of June 30, 1952, there were 102 state banks, 16 branches, one Military Facility, and 20 depositories having assets of $305,331,743 and deposits of $280,620,294, and 41 building and loan associations having assets of $50,269,080. On the same date 25 national banks with 39 branches had deposits of $490,472,000 and resources of $522,808,000.

## SOCIAL AND CULTURAL ACTIVITIES

**Education.** The first school in South Carolina was established in Charleston in 1701; it was run by John Douglas. Ten years later a free school was opened there for indigent children. While relatively little was done toward the advancement of public education until the next century, by 1826 thirty-two academies had been founded. The present free school system had its beginning in 1868. It is under the direction of an elected superintendent of education with the assistance of a board of education appointed by the governor. Separate schools are maintained for Negroes. Compulsory education laws require children from 6 to 14 years, or 16 years if unemployed, to attend school nine months annually.

During the school year 1951-1952 there were 3,279 public schools enrolling 512,199 pupils and employing 17,479 classroom teachers. In the elementary schools there were 386,142 pupils and 12,226 teachers; in the high schools, 126,057 pupils and 5,253 teachers. In addition to the public schools there were 27 private and denominational schools having 5,335 pupils and 252 teachers. The department of education works closely with the department of public welfare in vocational rehabilitation work and also maintains some special vocational schools. The value of school property was $120,068,668 in the 1951-1952 school year. During the same period $41,509,063 was paid in salaries of classroom teachers, the average salary of elementary teachers being $2,197 and that of high school teachers, $2,789. The 1951 General Assembly created a State Educational Finance Commission which has under way extensive reorganization of the school system, including full equalization of white and Negro schools. The funds for revitalizing the school system are largely derived from a three per cent retail sales tax which went into effect July 1, 1951.

The institutions of higher education maintained by the state are the University of South Carolina, at Columbia; Clemson Agricultural College, at Clemson; Winthrop College (The South Carolina College for Women), at Rock Hill; the State Colored Normal, Industrial, Agricultural and Mechanical College of South Carolina, at Orangeburg; and The Citadel (The Military College of South Carolina), at Charleston. Private institutions of higher learning include the College of Charleston, at Charleston; Erskine College, at Due West; Furman University, at Greenville; Newberry College, at Newberry; Presbyterian College, at Clinton; Wofford College, for men, at Spartanburg; and, for women, Coker College, at Hartsville, Columbia College at Columbia, Converse College, at Spartanburg, and Limestone College, at Gaffney. Claflin University, at Orangeburg, and Benedict College and Allen University, both at Columbia, are for Negroes.

**Social Measures.** The counties generally have some provision for care of the poor, but the State Department of Public Welfare provides old-age assistance and general assistance as well as aid to the blind, to dependent children, and to persons permanently and totally disabled. As of June 1951 there were 83,699 individuals on the relief rolls, receiving an average of $26.75 per month. Of the total, 42,870 received an average of $25.10 per month in old-age assistance; 1,606 needy blind persons received an average of $27.46; 19,254 dependent children received an average of $13.44; 3,714 individuals received an average of $20.75 in general assistance; and 2,319 persons totally and permanently disabled received an average of $32.15 per month. Total funds expended by the State Department of Public Welfare for the year ending June 30, 1951, amounted to $17,971,340. During the fiscal year 1951 the State Employment Security Commission had a total of 96,592 initial claims and made benefit payments to the amount of $6,572,907. During 1950 the monthly average of insured employment totaled $318,727, and wages reported to the Commission amounted to $748,000,000. The unemployment trust fund account totaled $53,500,297 on June 30, 1951.

*St. Philip's, Charleston, built in 1835-1838 from plans by Joseph Hyde, is the third church building to be erected by the first Anglican parish organized south of Virginia. Its lofty, octagonal tower, designed by Edward Brickell White, is one of the city's most famous landmarks.*

culosis sanatorium is at State Park, near Columbia. The Catawba Indian Reservation, comprising 652 acres, is located about 9 mi. east of Rock Hill. J. J. P.

**Cultural Activities.** Public libraries in the state are, almost without exception, county or regional libraries which now serve all but nine of the state's 46 counties. Forty bookmobiles carry books and library materials into the rural areas. The Charleston Library Society Library, organized in 1748, is the third of its kind established in the country. It contains many exceedingly rare volumes and an extremely valuable file of pre-Revolutionary newspapers dating as far back as 1732. The largest art collection in the state is that of the Gibbes Art Gallery in Charleston. The Columbia Museum of Art conducts an active program of contemporary and traditional art exhibits. The Charleston Museum, founded in 1773, is the oldest in the United States. It is devoted almost entirely to South Carolina culture. An open-air museum at Brookgreen Gardens, situated about 20 mi. north by road from Georgetown, exhibits one of the most notable collections of American bronze and marble statuary in the country. The leading musical event of its kind in the state is the Columbia Music Festival. Nonprofessional symphony orchestras perform periodically at Charleston, Greenville, and Due West, and the South Carolina Federation of Music Clubs has sponsored various musical projects and has endowed many scholarships. The ballads, folk songs, and Gullah chants for which South Carolina is famous have for many years been collected by the Southeastern Folklore Society. E. P. W.

## POPULATION

**General Statistics.** South Carolina had a population of 2,117,027 in the 1950 United States Census, an increase of 217,223, or 11.4 per cent over 1940. The average population per square mile in 1950 was 69.9 persons as compared with the national figures of 49.9. In 1950, 36.7 per cent of the population was classified as urban. The state ranks twenty-seventh in population and contains 1.41 per cent of the nation's total population. In 1950 the most populous of the state's forty-six counties was Greenville, which includes the city of Greenville, with a total of 168,152 persons. Charleston County, including the city of Charleston, was second with 164,856; Spartanburg County was third with 150,349, and Richland County, containing the capital of the state, Columbia, was fourth, with 142,565 persons. The largest cities in 1950 were Columbia, 86,914; Charleston, 70,174; Greenville, 58,161; and Spartanburg, 36,795. These are the only cities with a population over 25,000. Seven others have populations of over 10,000.

**Racial and Religious Groups.** According to the Census of 1950, 61.4 per cent of the population of South Carolina belonged to the white race, 38.8 per cent to the Negro race, and a total of 1,545 persons to other races. The foreign-born white population in 1950 included 907 from England and Wales, 816 from Germany, and 812 from Greece. In 1936 South Carolina had 4,263 churches with 710,163 members. In terms of numbers the three leading denominations were, in order, Baptist, Methodist, and Presbyterian.

**Occupational Groups.** In 1950 there were in the state 1,421,466 persons over 14 years of age; of the 798,177 persons in the labor force, 755,378 were employed. Manufacturing, with 36 per cent, and agriculture with 16.4 per cent of the employed, constituted the largest occupational groups.

## FAMOUS SITES AND PLACES

Charleston, founded with the early English settlement of the state, is filled with points of historic interest. For 120 years it was the capital of the province, and the city contains many buildings dating back to Colonial times, among them being several churches, many homes, the old powder magazine, the Dock Street Theater (the first wholly for drama in America), the museum, and the library. Columbia, established as the capital in 1786, has among its many historic features the State House, the University of South Carolina (third state university in the United States), and the First Baptist Church (meeting place of the Secession Convention).

South Carolina has a number of public and private gardens famous for their constructive planning and their flowers, especially azaleas and camellias. Among the better known are Brookgreen, near Georgetown; Swan Lake, near Sumter; Edisto, in Orangeburg; and Magnolia, Middleton Place, Cypress, and Mateeba, in the Charleston area. The southern part of the state contains a number of ante-bellum plantations which retain much of their former character.

There are nine state parks developed in co-operation with the National Park Service and six in co-operation with the United States Forest Service. These are widely distributed from the mountains to the seacoast and offer a wide variety of recreational opportunities. The National Park Service has established three sites of historic importance, namely, Pinckney National Monument in Charleston harbor, Cowpens National Battlefield Site in Cherokee County, and the Kings Mountain National Military Park in York County.

## HISTORY

**Exploration and Settlement.** The first Europeans to

reach South Carolina are believed to have been Spaniards. In 1521 an expedition consisting of two ships, the one commanded by Pedro de Quexos and the other by Francisco Gordillo, landed at the mouth of Winyah Bay seeking Indian slaves. In 1526 the Spanish established a settlement at Winyah Bay, but it was abandoned in a few months; a Spanish settlement at Parris Island in 1566 was maintained for several years. Hernando de Soto on his march to the Mississippi apparently passed through the region. The territory was claimed by Spain, although this claim was not fully recognized by the French or by the English. The French established a short-lived settlement at Port Royal in 1562. In 1663 Charles II granted the territory from sea to sea, between parallels 31° and 36°, to eight noblemen, later extending the grant to 29° and 36° 31′. William Sayle was appointed the first governor of the first English settlement, consisting of 148 people, including three Negro slaves, founded at Albemarle Point on the west bank of the Ashley River. In 1680 the center of settlement was removed to the peninsula between the Ashley and Cooper rivers, the present site of Charleston. Attractive terms were offered to settlers, encouraging them to come from England, France, the Barbados, and other colonies. By 1680 the settlement had 1,000 to 1,200 people; by 1700 its growth had reached nearly 16,000.

LOUIS TAGER FROM EWING GALLOWAY

*Monument to the defenders of Fort Sumter, object of an attack by Confederate forces on April 12-13, 1861, in the first engagement of the Civil War, stands on the Battery at Charleston, South Carolina.*

The Fundamental Constitutions, devised by Anthony Ashley Cooper, Earl of Shaftsbury, one of the Lord Proprietors, and John Locke, the English philosopher then serving as his secretary, were rejected by the colony, which in 1693 secured the right of initiating legislation. Disputes over the collection of quit-rents were bitter. The Church of England was made the established religion in 1706. North and South Carolina were separated in 1710, and the Proprietary control was overthrown in 1719 with the result that King George I sent Sir Francis Nicholson to South Carolina as Royal Governor, in 1721. Royal government did not check the rising tide of democracy; the popular assembly continued to outweigh both the governor and the council.

**Eighteenth Century.** A commerce in rice and indigo steadily expanded during the eighteenth century, but the prosperity of the colony at first largely depended on the Indian trade, in which the Carolinians daringly took the initiative, penetrating the wilderness, taking trade from the Spanish in Florida and alarming the French in Louisiana. Charleston, center of the Indian trade, became a cultural and commercial metropolis rivaling Philadelphia, New York, and Boston, the only cities exceeding it in population in 1775. Columbia succeeded Charleston as the capital in 1790.

The colony figured in Revolutionary agitation, voted troops as early as June 1775, forced the Governor to flee in September, and established a state government six months later. However, numerous Loyalists and the presence of British troops in 1780-1782 caused the state to suffer severely. Differences between the frontier regions and the wealthier coastal section did not prevent ratification of the Federal Constitution on May 23, 1788, but were reflected in the adoption of a new state constitution in 1790 which made the legislature practically supreme. In 1808 a revision of the constitution was made dividing representation equally between population and wealth; this revision remained in effect until 1868.

**Nineteenth Century.** Westward extension of the cotton plantation system overwhelmed early opposition to slavery interests. South Carolina, first as an opponent of protectionism in tariff and then as a rabid champion of slavery, took the lead in secession; its troops opened the Civil War by firing on Fort Sumter on Apr. 12, 1861. The state, which put 62,838 troops in the field, suffered heavily from the ravages of war, especially from Gen. William T. Sherman's march to the sea in 1865. Columbia was destroyed by fire.

The Reconstruction Era was particularly unfortunate in South Carolina. The election of Daniel H. Chamberlain, of Massachusetts, to the office of governor in 1874 aroused hopes of improved administration under the Radical Party then in power, but in 1876 when Gen. Wade Hampton, Confederate hero of the war and Democratic candidate, was elected governor, Chamberlain refused to vacate his office, on the ground that Hampton had been elected by questionable methods. The result was that two state governments, in bitter opposition, prevailed until the following year. Withdrawal of Federal troops from the state led to Chamberlain's relinquishment of office, to victory for Hampton's forces, and to disfranchisement of the Negroes. In 1890 acute distress among the farmers of the state, especially in the Piedmont region, led to the election of their candidate, Benjamin R. Tillman, who carried out a number of democratic reforms, including the establishment of agricultural and vocational education in the state. However, Tillman also established a state dispensary for the control of liquor which was ineffectively handled and resulted in widespread corruption.

**Twentieth Century.** State liquor dispensaries were abolished in 1907, but the control of liquor was to remain a campaign issue for many years; in 1933 South Carolina was one of the two states to vote for the retention of prohibition. During World War I the state contributed about 62,000 men to the armed forces, of whom 2,085 died in service.

Marked industrial development and, beginning with the administrations of Richard I. Manning (1915-1919), sound social progress have characterized the history of the state generally since the turn of the century. Notable work in the conservation of natural resources, begun in 1930, has been carried out under Federal auspices. In 1937 a child-labor law was passed prohibiting children under sixteen years of age from working in mines, factories, and textile establishments; and in 1947 a Federal court order, confirmed by the United States Supreme Court in 1948, established the right of Negroes to vote in primaries, annulled a discriminating

voter's oath, and ordered the admission of Negroes to all party committees and conventions. During World War II South Carolina contributed 136,000 men and 1,879 women to the army, and 51,482 men and 732 women to the navy.

J. J. P.

**SOUTH CAROLINA, STATE COLORED NORMAL, INDUSTRIAL, AGRICULTURAL AND MECHANICAL COLLEGE OF,** an accredited, coeducational, state-controlled college of arts and sciences for Negroes, occupying 450 acres in Orangeburg, S. C. Established in 1895, the college offered courses in agriculture, arts and science, and mechanic arts. The divisions of Home Economics, Agriculture, Arts and Sciences, and Mechanic Arts (later named Engineering and Industrial Education) were established in 1932; the Graduate Division in 1946; and the Law School in 1948. Degrees offered include the A.B. and the B.S. in liberal arts; the B.S. in agriculture, business administration, and engineering; the M.S.; the M.A.; and the LL.B. There is a large extension division.

Some scholarship aid is offered, but there is no loan fund. Dormitories and dining halls are provided for men and women. Sororities and fraternities are permitted, but members do not live in the houses. Opportunities for self-help enable students to earn part or all of their expenses. *For statistics see* COLLEGES AND UNIVERSITIES.

J. R. To.

**SOUTH CAROLINA, UNIVERSITY OF,** an accredited, coeducational, state-controlled institution occupying 46 acres in the city of Columbia, S. C. Chartered as South Carolina College in 1801, it was known as the University of South Carolina from 1866 to 1877. After a three-year period of inactivity, the college resumed operation in 1880 under the name of South Carolina College of Agriculture and Mechanics. The name reverted to the original form in 1882 and became the University of South Carolina in 1888. Again in 1891 the name was changed to South Carolina College. Finally in 1906 the present name was adopted. The many divisions of the university were founded as follows: College of Arts and Sciences, 1805; School of Pharmacy, 1865; School of Law, 1867; School of Education, 1882; Graduate School, 1906; School of Engineering, 1909; Summer School, 1914; Extension Division, 1915; School of Commerce (now the School of Business Administration), 1919; School of Journalism, 1923; and School of Social Work, 1934. The local chapter of Phi Beta Kappa was organized in 1926.

The degrees offered include the A.B. and the B.S. in liberal arts and in education; the A.B. in journalism; and the B.S. in business administration, pharmacy, and in civil, chemical, electrical, mechanical, and general engineering. Also offered are the LL.B.; the M.S.; the M.Ed.; the M.S.S.; the graduate degrees of civil, chemical, electrical, mechanical, and general engineering; the M.A.; and occasionally the Ph.D. Recent additions include a Department of Nursing, a Department of Homemaking, and a major in music.

Scholarships and graduate fellowships in varying amounts are offered and there is a loan fund available. Approximately half the students earn part of their expenses. Dormitories and dining halls are provided for men and women. Women from outside the city must live in the dormitories unless approval for other living arrangements is received from the dean of women. *For statistics see* COLLEGES AND UNIVERSITIES.

J. R. To.

**SOUTH CHARLESTON,** a residential town in western West Virginia, situated in Kanawha Co., on the Kanawha River, 2 mi. west of Charleston, of which it is a suburb. Its government is administered by a mayor and council. An interesting historic feature of the town is the Indian burial mound in Staunton Park, 175 ft. in circumference at the base and 30 ft. high. When opened by the Federal Government in 1883, it was found to contain many relics, including pottery fragments, stone weapons, and some dozen skeletons, one 7 ft. in height. Transportation is provided by the Chesapeake and Ohio Railroad and by the All American Aviation air line. The town is known for the manufacture of chemicals, its principal industry. Pop. 1950, 16,686.

**SOUTH CHINA SEA,** a large, tropical body of water off southeast Asia. It is partly enclosed by South China and Formosa on the north, the Philippine Islands on the east, Borneo on the south, and French Indochina and Malaya on the west. Formosa Strait connects the sea with the East China Sea, and there are two large gulfs: that of Siam, in the southwest, and that of Tonking, in the northwest. Numerous islands and reefs and frequent tropical storms of high intensity make parts of the sea hazardous for shipping, although around its periphery are to be found such fine, important harbors as Hong Kong and Macao, Manila, Brunei, Singapore, Saigon, and Haiphong.

J. E. F.

**SOUTH DAKOTA,** commonly called the Sunshine State, one of the north central states of the United States. Its name is derived from the Dakota or Sioux Indians who were the chief inhabitants of the region when the first white men appeared. Rectangular in shape and lying roughly between 96° and 104° 3′ W. long. and 43° and 46° N. lat., it is bounded on the north by North Dakota, on the east by Minnesota and Iowa, on the south by Nebraska, and on the west by Wyoming and Montana. It embraces an area of 77,047 sq. mi., of which 511 sq. mi. are water surface. It ranks fifteenth among the states in size, being slightly smaller than Nebraska and larger than the combined area of New England.

GREAT SEAL OF THE STATE OF SOUTH DAKOTA

South Dakota and North Dakota both entered the Union on Nov. 2, 1889, and are counted as the fortieth and thirty-ninth states to achieve statehood. The state motto is "Under God the People Rule"; the state flower is the pasque flower; the state bird is the ring-necked pheasant; the state song is *Hail, South Dakota.* There are 64 organized and three unorganized counties in the state; the capital is Pierre.

### PHYSICAL FEATURES

**Topography.** The state has three main physiographic sections: the Prairie Plains, the Great Plains, and the Black Hills. The Prairie Plains section is a continuation of the prairies of Iowa and Minnesota and comprises most of the area lying east of the Missouri River. Its elevation ranges

from 1,100 to 2,000 ft. Generally glaciated, it is differentiated by (1) the Dakota or James basin, a large shallow trough from 50 to 75 mi. wide and 250 mi. long; (2) the Coteau des Prairie, or eastern divide, which is a rough, broad, lake-dotted plateau some 60 or 70 mi. in width and standing from 500 to 700 ft. above the James River valley on the west and the Red, Minnesota, and Big Sioux valleys on the east; and (3) the Coteau du Missouri, or the Missouri divide, 25 to 30 mi. in width, lying from 200 to 700 ft. above the James basin and the gorge of the Missouri River and possessing the climatic and physical characteristics of the Great Plains region into which it merges.

The Great Plains, with an average elevation of 2,800 ft., present a varied topography including extensive, nearly level areas as well as wide stretches of hilly upland surmounted by lofty conical and flat-topped buttes and seamed by deep gorges. "Badland" formations are common features, usually forming the bluffs of river valleys or the sides of large buttes, the largest and most picturesque being the White River Badlands, which cover an area over 100 mi. long. The Black Hills are a mountainous area with an elevation of over 5,000 ft., elliptical in shape and about 100 mi. long and 50 mi. wide. Two thirds of the area lies in South Dakota, contiguous to Wyoming. Harney Peak, in the central part, has an elevation of 7,242 ft., the highest point in North America east of the Rocky Mountains.

The Missouri is the principal river, flowing through the middle of the state from north to south and draining most of the area. In the northeastern corner lies the continental watershed, the southern part draining through Big Stone Lake and the Minnesota River into the Mississippi basin, while the northern part drains through Lake Traverse and the Red River of the North into Hudson Bay. The tributaries of the Missouri in the eastern half of the state are the Big Sioux, the Vermillion, and the James, all flowing in a southerly direction. In the western part of the state the Grand, the Moreau, the Cheyenne, and the White follow the eastward slope toward the Missouri, cutting gorges and trenches in their course and contributing to the butte and canyon topography so characteristic of the Great Plains region in South Dakota.

Numerous lakes of glacial origin are found in the northeastern section, the so-called Lake Region of South Dakota. They vary from large lakes, several miles across, to small lakes that are shallow and hold water only during wet seasons. Since the 1930's, 1,185 artificial lakes have been constructed, most of them under the water conservation program fostered by local, state, and federal agencies.

**Climate.** The state has an invigorating climate with recorded extreme temperatures of 115° F. and —46° F. The mean annual temperature is 45° F. Average annual precipitation is 20 in. but ranges from 25 in. in the eastern section to 14 in. in the northwestern part. Normally, three fourths of the rainfall occurs during the growing season. The rainfall, however, varies greatly from year to year with corresponding effects on crop production. South Dakota has had several severe droughts in the past, notably in the periods 1886-1894, 1910-1911, and 1930-1936. The average growing season is 135 days but ranges from 105 in the western part to 145 days in the southeastern section. Contrary to popular belief, blizzards are not common but strike with great violence when they occur.

**Soil.** Most of eastern South Dakota has a clay-loam soil of glacial origin, similar to that found in Minnesota and Iowa. This soil is rich in humus and is dark colored to a considerable depth. The predominant soil type west of the Missouri River is Pierre clay or "gumbo," derived from the weathering of Pierre shale which outcrops widely. It does not absorb moisture readily, has a strong tendency to cake when dry, and becomes sticky when wet. Nevertheless, "gumbo" yields abundantly under favorable moisture conditions. Clay loams and sandy loams are also widespread in western South Dakota.

**Forests.** Wooded areas, occupying about 3 per cent of the total area of the state, are confined mostly to the Black Hills and lie for the greater part within the boundaries of the Black Hills National Forest, which covers 605,054 acres, and of the Harney National Forest, which has an area of 720,317 acres. Custer National Forest, in the northwest section of the state, has an area of 77,826 acres. The woods consist chiefly of yellow pine, white elm, spruce, red cedar, bur oak, cottonwood, box elder, and aspen.

**Flora.** Flowering plants in the northeast lake region include the pink wild rose, buttercup, primrose, pink bearded tongue, purple and yellow violets, blazing star, and, in the creeks, white lilies. Prominent among wild flowers of the central section of the state are the black-eyed Susan, wild orange geranium, prickly poppy, and Mariposa lily. From the Missouri River westward are found the gumbo lily, yucca, and a cactus bearing yellow flowers. In the Black Hills region the blue flag or iris is common, also the wood orchid, bluebell, yellow lady slipper, and larkspur.

**Fauna.** Coyotes were at one time so plentiful that the state was frequently referred to as the Coyote State. Buffalo, also once present in great numbers, have been reduced to small herds confined to Custer State Park and Wind Cave National Park. In the Black Hills elk and deer are not uncommon; smaller mammals found there include the bobcat, beaver,

*Farmer cultivating corn on a large farm at Centerville, South Dakota, operates a general-purpose tractor equipped with a two-row cultivator.*

EWING GALLOWAY

raccoon, porcupine, and several kinds of squirrels. The antelope, jack rabbit, and prairie dog are encountered west of the Missouri River; eastward, the badger, gopher, muskrat, skunk, weasel, and jack rabbit survive.

Twenty-four kinds of reptiles, including snakes, lizards, and turtles, are native to the state. The bull snake is the most common, the rattlesnake being rarely found east of the Missouri River, and the horned lizard is prevalent in many localities.

Approximately three hundred species of birds are found in the state. Waterfowl, plentiful in the lakes of the northeastern section, include ducks, geese, swans, pelicans, cranes, cormorants, herons, gulls, and the water ouzel. In the eastern part of the state are found the meadow lark, flicker, goldfinch, kingfisher, robin, swallow, brown thrush, humming bird, Chinese pheasant, prairie chicken, ring-necked pheasant, Hungarian partridge, and the red-winged and the yellow-headed blackbird. West of the Missouri grouse are still abundant, and the golden and the bald eagle are not uncommon. In the Black Hills are encountered the catbird, wood thrush, bluebird, rock wren, crossbill, woodpecker, and many species of warblers. The magpie, screech owl, great horned owl, water buzzard, and prairie chicken occur throughout the state.

There is excellent fishing for trout in the mountain creeks, and for pike, bass, and other game fish in the numerous lakes. Eight state fish hatcheries and rearing ponds are maintained.

A definite program for the conservation of wild life was inaugurated in 1907, when all wild birds were declared the property of the state; a game code was established in 1909. A State Game and Fish Commission, created in 1913, was changed to the Department of Game, Fish, and Parks in 1945. The Izaak Walton League, established in the state in 1925, has worked in close harmony with the department in sponsoring conservation legislation and in promoting conservation sentiment and practices.

## ECONOMIC RESOURCES AND ACTIVITIES

**Mining and Minerals.** Mineral production in South Dakota in 1950 totaled $26,870,174. Gold, the principal metal mined, contributed $19,879,860 to this total, most of it from the famous Homestake Mine, which was located in 1877 and has become the largest gold mine in the Western Hemisphere. South Dakota in 1950 ranked first among the states of the Union in the output of gold, producing 567,996 troy ounces, compared with the 457,551 troy ounces produced in Utah and 417,231 troy ounces produced in California in the same year. Materials used in building and in highway construction are mined and quarried in large volume, ranking next to gold in value. These materials include sand, gravel, an attractive mahogany granite, and Sioux quartzite, produced extensively in the eastern section of the state. In 1950 about 124,975 tons of bentonite were produced, the value of which was estimated at $1,766,522. Limestone is extensively quarried, and feldspar and lithium are produced in appreciable quantities, also iron ore, gypsum, and mica. Some lignite coal is mined, large deposits of which exist in the northwestern part of the state where they are relatively inaccessible to transportation. Manganese deposits of low-grade ore, found along the Missouri River west of Chamberlain, have been subjected to pilot mill tests but cannot be profitably exploited under present processing methods.

**Agriculture.** The state is primarily agricultural with 86 per cent of its surface area in farms, ranking ninth with respect to total area of first-grade land. The average size per farm in 1950 was 674 acres, and the average value per acre was $31.31. The value of the farms, including land and buildings, was $1,402,235,000. In 1944 there were 52,895 acres under irrigation, represented by 708 farms. Irrigation in 1952 was mostly confined to the Belle Fourche Reclamation Project in Butte County, inaugurated in 1908, and the Angostura Valley Project in Fall River County, put in operation in 1952.

A mixed farming pattern prevails in the eastern half of the state. The western section is chiefly devoted to stock raising, although grain crops are produced in many areas. Corn is the chief crop in the southeastern counties while spring wheat predominates in the northern part. In recent years blue grass seed has become an important cash crop for the prairies; production in 1951 amounted to 973,000 bu.

Leading South Dakota Crops
(1951)

| | *Acreage Harvested* (1,000) | *Production* (1,000) |
|---|---|---|
| Corn | 3,892 | 85,624 bu. |
| Wheat | 3,839 | 57,260 bu. |
| Hay | 4,748 | 4,517 tons |
| Oats | 3,145 | 116,363 bu. |
| Barley | 838 | 19,693 bu. |
| Flaxseed | 573 | 4,584 bu. |
| Rye | 512 | 6,656 bu. |
| Alfalfa seed | 99 | 50 bu. |
| Potatoes | 11 | 1,650 bu. |

Cash receipts from crops in South Dakota totaled $195,402,000 in 1951.

**Animal Industry.** Cash receipts from livestock and livestock products in South Dakota in 1951 totaled $600,607,000. Dairying and feeding of beef cattle are the forms of cattle raising in the eastern part of the state; range production under a modified ranching program prevails in the Great Plains area. In 1950 there were 27,000 livestock brands on record. The average ranch contains 1,464, acres; a few big cattle outfits, however, run their stock over as many as 30,000 acres. As of Jan. 1, 1952, there were 2,826,000 cattle in the state, valued at $562,374,000; 350,000 cows and heifers, valued at $95,900,000; 1,774,000 swine, valued at $67,589,000; 1,039,000 sheep, valued at $30,747,000; 127,000 horses and mules, valued at $4,461,000; and 9,077,000 chickens, valued at $11,800,000. In 1951, 350,000 turkeys were produced, representing a total value of $2,017,000.

**Manufacturing.** Industrial activities in the state consist primarily of processing farm products. In 1947 there were 494 manufacturing establishments furnishing employment to 10,265 persons who were paid $25,796,000 in salaries and wages. Of these employees 8,062 were production workers who received $19,193,000 in wages. The value added to products by manufacture in 1947 totaled $51,398,000.

Leading South Dakota Manufactures
(1947)

| | *Avg. No. of Persons Employed* | *Wages Earned in Year* ($1,000) | *Value Added by Manufacture* ($1,000) |
|---|---|---|---|
| Food and kindred products | 6,827 | 17,637 | 35,246 |
| Printing and publishing industries | 1,152 | 2,669 | 5,566 |
| Lumber and products except furniture | 994 | 2,160 | 3,506 |

ucts, chemicals and allied products, and fabricated metal products.

**Transportation.** In 1952 there were 98,597 mi. of rural roads in the state, of which 3,566 mi. were improved paved roads and 2,630 mi. were of gravel surface. In 1951 there were 296,426 motor-vehicle registrations, of which 219,233 were automobiles and 75,402 commercial motor vehicles. In 1952 there were 3,960 mi. of steam railways in South Dakota, the chief systems being the Chicago and North Western Railway and the Chicago, Milwaukee, St. Paul and Pacific Railroad. As of April 1952, there were 75 airports in the state and about 150 private landing strips. Nine cities had airway service.

## GOVERNMENT AND POLITICS

**Constitution.** The constitution adopted in 1889 contains many provisions that are detailed in character. The amending process, consequently, has been freely resorted to. Over fifty amendments have been accepted by the voters, including one at the 1952 election.

**Government Structure.** In addition to the governor and lieutenant governor, six leading administrative officers are elected by the voters, as are also the members of the Public Utility Commission. The governor is elected to a two-year term and is not eligible for more than two successive nominations in the primary. The candidates for governor are chosen by a direct primary except when no candidate receives 35 per cent of the vote cast, in which case nomination is by party convention; all other elective officials are nominated by party convention, except the superintendent of public instruction and judges who are nominated and elected on a nonpolitical ballot.

The bicameral legislature is composed of 35 senators and 75 representatives, elected every two years. It convenes at Pierre, the capital, on the first Monday after the first Tuesday in January of odd-numbered years for a limited session of 60 days.

The judicial department, chosen by nonpolitical ballot, consists of five supreme court judges, elected for six-year terms, and 20 circuit judges, holding jurisdiction over 12 districts and elected for four-year terms.

**State Finance.** Receipts of state money from all sources for the fiscal year ending June 30, 1951, amounted to $71,689,000. This included $35,370,000 collected by the division of taxation and licensing, $3,818,000 collected by counties, and $15,183,000 received in federal aid. The collections of the division of taxation and licensing included $17,091,000 from retail sales and use tax, $1,300,000 from sales tax on liquor, beer, and cigarettes, $11,119,000 from motor vehicle fuels, $2,702,000 from motor vehicles and operators, $51,000 from chain stores, $2,129,000 from liquor licenses, and $711,000 from ore tax. The revenues collected by the counties included $1,935,000 from general property tax and $502,000 from inheritance tax. Federal aid included $6,546,000 for highways, $3,633,000 for old-age assistance, and $1,191,000 for other forms of public welfare.

General expenditures for the fiscal year ending June 30, 1951, totaled $69,068,795, and included $8,394,000 for interest and sinking fund, $17,632,000 for highways, $8,062,000 for educational institutions, $2,792,000 for penal and charitable institutions, $9,383,000 for public welfare, and $11,865,000 to governmental subdivisions.

The bonded indebtedness at the end of the fiscal year 1951 was $20,815,000, representing veterans' bonus and rural credit bonds; a sinking fund of $17,775,000 assured the liquidation of the entire debt by 1954.

**Military Organization.** The reorganization of the National Guard was undertaken in 1946. It consisted of a regiment of infantry, a battalion of field artillery, a battalion of combat engineers, a company of engineers, an air force fighter squadron, and an army band. The organization is administered by a state headquarters under the adjutant general. During 1950 and 1951 three units were ordered to active duty but were all returned to state control by Dec. 1, 1952, at which time they were reorganized with an authorized personnel of 1,854 men and officers.

## SOCIAL AND CULTURAL ACTIVITIES

**Education.** The public school system is headed by the Superintendent of Public Instruction, elected for a two-year term on a nonpolitical ballot, and comprises 3,390 districts, including 3,039 common, 264 independent, and 87 consolidated districts. The total cost of maintenance in 1951-1952 was $30,746,494. Local school levies are supplemented by state aid in the form of income derived from the permanent school fund and rentals on school lands and by direct legis-

lative appropriations which in 1951 amounted to $3,500,000 for the biennium.

Attendance at school in South Dakota is compulsory for all children from seven to sixteen years of age inclusive. In 1951-1952 the public elementary schools enrolled 91,975 pupils; the public secondary schools enrolled 29,475 pupils. The public schools of the state employed 1,704 men teachers in the same year, and 5,517 women teachers.

Seven institutions of higher learning are maintained by the state under the governance of a board of regents, consisting of 5 members appointed for six-year terms: the University of South Dakota, at Vermillion; the South Dakota State College of Agriculture and Mechanic Arts, at Brookings; The South Dakota School of Mines and Technology, at Rapid City; Black Hills Teachers College, at Spearfish; General Beadle State Teachers College, at Madison; Northern State Teachers College, at Aberdeen; and Southern State Teachers College, at Springfield. Private institutions of higher learning include Augustana College, at Sioux Falls; Dakota Wesleyan University, at Mitchell; Huron College, at Huron; and Yankton College, at Yankton.

**Social Measures.** The Public Welfare Commission of the state administers old-age assistance, aid to the blind, and aid to dependent children. The care of other poor persons remains the responsibility of the county commissioners of each county. Old-age assistance is provided to persons sixty-five years of age or over who have resided in South Dakota for one year immediately preceding application and do not have sufficient income or other resources to provide "a reasonable subsistence compatible with decency and health." Payments were made during the fiscal year of 1951-1952 to 11,983 aged persons in the total amount of $5,938,000. During the same period an average per month of 2,556 families received payments for dependent children totaling $2,191,000. In the same year payments amounting to $99,308 were made to an average of 213 blind persons per month, and payments of $62,427 were made to 152 disabled persons. Unemployment insurance benefits begin in South Dakota at a minimum of six dollars a week for a period of ten weeks and progress to a maximum amount of $20 a week for twenty weeks. During 1951 the Employment Security Department collected the sum of $1,620,000 in taxes from employers and paid $714,610 in unemployment benefits to 4,434 persons.

Charitable and penal institutions maintained by the state include the School for the Blind at Gary, the School for the Deaf at Sioux Falls, the School and Home for the Feebleminded at Redfield, the State Hospital for the Insane at Yankton, the State Soldiers' Home at Hot Springs, the State Sanatorium at Sanator, the State Training School at Plankinton, and a penitentiary at Sioux Falls. As of Oct. 1, 1952, there were 74 general hospitals in the state providing a total of 3,010 beds.

## POPULATION

**General Statistics.** According to the United States Census, South Dakota had a population of 652,740 in 1950, ranking it forty-first in population among the states, compared with 642,961 in 1940. The density of population in 1950 was 8.5 persons per square mile. Of the 1950 population, 216,710, or 33.2 per cent, were classified as urban. In 1950 the most populous county was Minnehaha, which includes Sioux Falls, the largest city; it contained a total of 70,910 persons. Pennington County, ranking second with 34,053 persons and containing Rapid City, had the most rapid rate of growth with an increase of 43.1 per cent for the ten-year period. Brown County, including Aberdeen, ranked third with 29,676. The leading cities in 1950 were Sioux Falls (52,696), Rapid City (25,310), and Aberdeen (21,051). Other cities with a population of over 10,000 were Huron (12,788), Watertown (12,699), Mitchell (12,123).

**Racial and Religious Groups.** In 1940, 96.3 per cent of the population was listed as white. The Indian population in 1950 was 23,344, concentrated mostly in eight reservation areas. The large influx of European immigrants was reflected in a high percentage of foreign born in the census records prior to 1900, constituting 22 per cent of the total population in 1890. By 1940 only 44,054, or 6.9 per cent,

were so listed. These included 8,708 from Norway, 8,304 from Germany, 6,468 from Russia, 4,361 from Sweden, and 3,721 from Denmark. According to the state census of 1945, the leading religious denominations and their respective memberships were Lutheran, 147,448; Roman Catholic, 91,835; Methodist Episcopal, 65,557; Presbyterian, 26,579; and Congregational, 26,150.

**Occupational Groups.** In 1940 there were 477,255 persons in the state over 14 years of age; of the 239,826 in the labor force, 204,514 were employed, of which nearly half, or 48.1 per cent, were employed in agriculture. The wholesale and retail trade constituted the next largest occupational group with 14.7 per cent. Professional and related services accounted for 8.8 per cent; personal services, for 5.7 per cent, and manufacturing, 4.5 per cent.

## FAMOUS SITES AND PLACES

Most of the Black Hills area is contained within the boundaries of the Black Hills National Forest, the Harney National Forest, and Wind Cave National Park. Custer State Park is one of the largest state parks in the United States. The Badlands National Monument, administered by the National Park Service, comprises 154,119 acres in a strip 40 mi. long and 5 to 20 mi. wide in the White River Badlands. In the Black Hills is also located Mount Rushmore National Memorial consisting of busts of George Washington, Thomas Jefferson, Abraham Lincoln, and Theodore Roosevelt carved by Gutzon Borglum out of the massive granite face of a mountain 6,050 ft. high. Other historic sites are Jewel Cave National Monument, which exhibits a variety of crystalline formations, and Fossil Cycad National Monument, which contains many fine petrified ferns.

## HISTORY

**Exploration.** The expedition of 1742-1743, headed by the French Sieur de La Vérendrye and his two sons, is the first recorded contact of Europeans with the region, although French explorers may have reached the eastern border as early as 1682. The principal Indian inhabitants during the early period were the Arikaras, who lived in villages of earthen lodges along the Missouri in the central part of the state, and the various divisions of the Sioux or Dakota who entered the region from Minnesota after 1750.

**Early Nineteenth Century.** The United States acquired title under the Louisiana Purchase of 1803. Following the Lewis and Clark expedition to the Oregon coast during 1804-1806, the American fur traders extended their operations into the upper Missouri Valley. South Dakota became studded with trading posts, especially along the Missouri where Fort Pierre, established in 1832, became a leading post of the Upper Missouri Outfit, a subsidiary of the American Fur Company. The arrival of the *Yellowstone* at Fort Pierre in June 1831 marked the introduction of steamboat navigation to the upper Missouri River basin. The first attempt at permanent settlement was made by town-site speculators in the Big Sioux Valley in 1857. Their effort to establish a territorial government failed, and the outbreak of hostilities among the Santee Sioux in Minnesota in 1862 led to the temporary abandonment of the Sioux Falls town site. Permanent settlements were planted at Vermillion and Yankton in 1859 following the relinquishment of title to the region by the Yankton Sioux under a treaty signed in 1858.

**Territorial Period.** Dakota Territory was created by Congress on March 2, 1861, and the first legislature convened in March 1862. Indian wars, droughts, grasshopper plagues, and lack of transportation facilities retarded the growth of the territory prior to 1868. Construction of a railroad from Sioux City to Yankton in 1872 and 1873 and an influx of European immigrants including Bohemians, Germans, Russians, and Scandinavians were factors in the growth that followed.

**Gold Rush.** During the 1870's a gold rush created a mining community in the Black Hills and furnished wide publicity for the entire territory. The Black Hills region was a part of the Great Sioux Reservation created west of the Missouri River by the Sioux treaty of 1868. The discovery of gold by two miners who accompanied the military expedition of General George A. Custer into the Black Hills in July 1874 caused a stampede into the area in violation of the treaty. The first party of miners reached French Creek near the present site of the city of Custer on Dec. 28, 1874. When the presence of gold in paying quantities was confirmed by the geological expedition headed by Walter P. Jenney in 1875, the government ceased trying to eject the miners. The Indian hostilities that followed culminated in the battle of the Little Big Horn on June 25, 1876, when General Custer's command was annihilated by Chiefs Sitting Bull and Crazy Horse. The treaty of 1877 ended the conflict and provided for the cession of the area west of 103° W. long., including the entire Black Hills region, and the right of way for three wagon roads across the reduced reservation. The peak of the gold rush was reached in 1877 when quartz mining replaced the placer operations.

**Great Dakota Boom.** The gold rush was followed by the "Great Dakota Boom," which increased the population from 98,268 in 1880 to 348,600 in 1890 and resulted in the complete occupation of the eastern half of the state during the period from 1877 to 1886. The penetration of this area by the railroads was a major factor, but favorable weather conditions and a liberal public land policy also contributed to the boom. This was followed by a period of drought and the financial depression of the 1890's, which resulted in a sharp decline in the population. There was also a marked shift from wheat culture to crop diversification during the recession.

**Statehood.** A movement for statehood and the division of

*A stone monument erected at Fort Pierre, South Dakota, marks the ground in which the Vérendryes in 1743 buried a lead tablet to claim the region for France. This tablet, found in 1913, is the first written record of the visit of white men to South Dakota.*

COURTESY OF THE SOUTH DAKOTA STATE PUBLICITY DEPARTMENT

Dakota Territory was initiated as early as 1877. A citizens' convention, organized by the southern counties of the territory, met at Sioux Falls in 1883 to draw up a constitution which was endorsed by the voters. Two years later another convention drafted a second constitution. The voters in the southern half likewise endorsed the constitution of 1885 and actually elected a full slate of state officials, including a legislature which met at Huron to place the claims for statehood before the country. In the meantime, partisan opposition to division in both the northern counties and Congress served to delay Congressional action. After the national election of 1888 which resulted in a Republican victory, the Democratic Party abandoned its opposition. Following the enactment of the enabling act in February 1889, providing for division at the seventh standard parallel, a third constitutional convention met at Sioux Falls in May 1889 to readopt the constitution of 1885 except for certain revisions required by Congress. On Nov. 2, 1889, South Dakota became the fortieth state, with A. C. Mellette as the first governor. The selection of Pierre as temporary capital was made permanent in a spirited contest with Huron, Watertown, Sioux Falls, Mitchell, and Chamberlain in 1890, and again with Mitchell in 1904.

During the first decade of statehood additional areas were opened to settlement on a portion of the Great Sioux reservation as well as on the Sisseton and Yankton reservations, but adverse climatic and economic conditions prevented a boom. The western plains remained an important part of the northern cow country although the open range industry had given way to modern forms of ranching. The economic and political unrest of the period was reflected in the Populist movement growing out of the Farmers' Alliance, which became a potent organization of protest in the Dakotas. Fusion with the Democrats and Free Silver Republicans in 1896 and 1898 resulted in the election of a Populist governor. Legislative efforts to regulate railroads failed, but the adoption of the first initiative and referendum law in the United States in 1898 was a direct contribution of the Populist movement.

*SYLVAN LAKE IN THE BLACK HILLS OF SOUTH DAKOTA*

COURTESY OF THE CHICAGO, BURLINGTON & QUINCY RAILROAD

**Twentieth Century.** Economic conditions improved after 1900. A combination of circumstances brought about another boom. Weather conditions were again favorable. Improved financial conditions and a heavy influx of homesteaders in the region west of the Missouri, particularly on newly opened Indian lands, led to the resumption of railroad construction. Lines were built from Pierre and Chamberlain to Rapid City in 1906 and 1907. The Chicago, Milwaukee and St. Paul also pushed its transcontinental line from the Missouri River at Mobridge along the northern edge of the state into North Dakota. The population of the state increased from 401,570 to 583,888, or 45 per cent, between the years 1900 and 1910.

The boom was temporarily interrupted by intense drought in 1910 and 1911, resulting in an exodus of many homesteaders from the Great Plains area where cropping methods were not suited to the region. The return of favorable weather conditions, however, accompanied by the stimulus of World War I and the increased use of power machinery, led to a tremendous expansion of agriculture which, in turn, resulted in over-production and inflated real estate values as well as the further extension of grain crops into grazing areas. The state was consequently hard hit by the deflation of the 1920's and the severe drought that set in after 1930. The intensity of this agricultural depression was indicated by the large relief roll in 1935 and the failure of two-thirds of the state's banks between 1920 and 1935.

Through the application of land-conservation methods and the introduction of scientific land-use programs, the farming situation greatly improved, so that by the end of World War II farm tenancy had declined, bank deposits had reached an all-time high, and farm mortgage indebtedness was at a low level.

Under the Flood Control Act passed by Congress in 1944, a vast program was authorized for the comprehensive development of the Missouri River basin, which, in South Dakota, included four multiple-purpose dams on the main stem of the Missouri and the construction of seven reservoirs for irrigation. The Fort Randall dam near the Nebraska boundary line was started on July 30, 1946, to supply large areas in South Dakota and Nebraska with electric power as well as to alleviate danger from the periodic floods to which the Missouri Valley has been subjected. Construction on the Oahe Dam, 7 mi. north of Pierre, was started on Sept. 16, 1948. H. S. S.

**SOUTH DAKOTA, UNIVERSITY OF,** an accredited, coeducational, publicly controlled institution occupying 62 acres of land in Vermillion, S.D. It was started as the University of Dakota by an act of the first territorial legislature in 1862, and the act incorporating the university was passed at the next session. In 1881 seventy-two sections of public land were granted by Congress for the use and support of the university, an endowment consisting of about 80,000 acres. First instruction was given in 1882. The divisions founded since that time are: the College of Arts and Sciences, 1888; the School of Law, 1901; the School of Medicine, 1907; the School of Education, 1927; the School of Business Administration, 1927; the Graduate School, 1929; and the College of Fine Arts, 1929. Among the degrees offered are the A.B. in liberal arts; the B.F.A.; the B.S. in business administration; the B.S. in medicine, which includes two years of preprofessional work; and the B.S. in education. Graduate

work leading to the A.M., Ed.M., and the M.Mus. is given in the Graduate School. The local chapter of Phi Beta Kappa was established in 1926.

Some scholarship and fellowship assistance is offered. However, most of it is restricted to applicants from South Dakota. Opportunities for self-help enable approximately one third of the students to earn part of their expenses. There are dormitories for women but none for men. Fraternities and sororities maintain residences for their members. *For statistics see* COLLEGES AND UNIVERSITIES. J. R. To.

**SOUTH DAKOTA SCHOOL OF MINES AND TECHNOLOGY,** an accredited, coeducational, state-controlled technological school occupying 100 acres in Rapid City, S. D. It was established by the Dakota Territorial Legislature as the Dakota School of Mines in 1885, and first instruction was offered two years later. Although the college is a coeducational institution, very few women enroll. The degrees offered are the B.S. in chemistry, in physics, and in chemical, civil, electrical, general, geological, mechanical, metallurgical, and mining engineering, and the M.S. in engineering. To qualify for the M.S. in engineering, candidates must have the bachelor's degree from the South Dakota School of Mines and Technology, five years' successful experience in a responsible technical position, and must submit a thesis. There is very little scholarship aid, but many students find it possible to earn part of their expenses. Some dormitories are provided and members may live in campus fraternity houses. *For statistics see* COLLEGES AND UNIVERSITIES. J. R. To.

**SOUTH DAKOTA STATE COLLEGE OF AGRICULTURE AND MECHANIC ARTS,** an accredited, coeducational, state-controlled technological college occupying a 40-acre campus in Brookings, S. D. It was chartered as Dakota Agricultural College in 1883, and first instruction was given in the following year. The name was changed to the State College of Agriculture and Mechanic Arts in 1907. In 1924 the institution was organized into five divisions: agriculture (instructional, experiment station, and agricultural extension); engineering; home economics; pharmacy; and general science. Degrees offered include the B.S. in engineering, general science, agriculture, pharmacy, home economics, printing, and journalism, and the M.S. Graduate and undergraduate scholarship aid is available and there is a loan fund. Many students find opportunities to earn part of their expenses. Male freshmen and sophomores and all women not living at home must live in dormitories. There are no fraternities or sororities on campus. *For statistics see* COLLEGES AND UNIVERSITIES. J. R. To.

**SOUTHEAST ASIATIC AND JAVANESE ART.** Under the title of "Southeast Asiatic and Javanese Art" we may include the art of the regions designated by the modern geographical names of Ceylon, Siam, Indochina, and Java. The beginnings of the art of all these outposts of Indian civilization date from the introduction of Buddhism and Hinduism, with the attendant importation from the Indian mainland of completely developed iconographical and stylistic canons.

### CEYLON

**Early Period.** Art in Ceylon may be said to begin with the introduction of Buddhism by the son of the Indian Emperor Aśoka in the third century B.C. Although the dedication of many religious structures and even Buddhist images is traditionally ascribed to the first century after the introduction of Buddhism, the real florescence of art in Ceylon begins with the establishment of the capital at Anuradhapura in the first century B.C. Among the earliest foundations were the enormous brick mounds or dagabas constructed to enclose corporeal relics of the Buddha. They retain the essential form of the Indian stupa with its characteristic hemispherical dome and superstructure of umbrellas on a mast emerging from the summit of the cupola. In scale they approximate the dimensions of all but the largest Egyptian pyramids.

EWING GALLOWAY

*The Buddha Tooth, enshrined in the Temple of Dalada Maligawa, at Kandy, Ceylon, is contained in a bell-shaped cover encrusted with hundreds of precious stones.*

The earliest sculpture at Anuradhapura dates from the second to the fifth century A.D. and consists of extremely hieratic and monumental Buddhist images in a style clearly derived from the contemporary Indian sculpture under the Later Andhra Dynasty, on the southeast coast of India.

The one monument of painting from this earliest period of Singhalese art is the series of wall paintings that formed a part of the decoration of the palace of Karsapa I at Sigiriya in central Ceylon. The wall paintings, located in a pocket in the vertical cliff, represent Apsarases, or celestial maidens. The figures are extremely sensuous in effect; they are a kind of Singhalese version of the style of the Indian wall paintings of the Gupta period at Ajanta.

**Later (Medieval) Period.** What is often described as the medieval period of Singhalese art begins with the abandonment of Anuradhapura to Tamil invaders from South India in the eighth century and the establishment of the capital at Polonnarūwa. The last great florescence of Singhalese art dates from the reign of Parākrama Bāhu (1164-1197). The sculpture of this period, as exemplified by the colossal Nirvana group of the Gal Vihāra, reveals a persistence of the traditions of the Gupta style and a peculiarly moving

presentation of the Buddha's serenity that can only be described as a special Singhalese contribution to Buddhist art. The colossal portrait statue of the king Parākrama Bāhu at Polonnarūwa is an impressive work of artistic genius.

Among the buildings at Polonnarūwa is a pyramidal temple or *prasada* built for the king's Cambodian mercenaries. A number of other structures, notably the circular Potgul Vihāra, are remarkable for their great beauty of proportion and the use of relief friezes to ornament the otherwise unadorned stone surfaces of the façades.

## INDOCHINA AND SIAM

**Pre-Khmer Period.** The history of art in Siam and Cambodia involves the transformation of originally Indian forms by peoples whose artistic capacity was in every sense equal to the task of evolving modes of expression suitable to the needs of their religion and environment. When Indian Hindu and Buddhist missionaries first made their way to the earliest centers of the Siamese and Cambodian civilizations, they brought with them the ready-made receipts for religious imagery developed in India in the Gupta period, so that some of the Buddha statues unearthed at the first Siamese capital of Dvāravatī and the earliest Cambodian shrines at Sambor seem to be repetitions in local stone of Indian models. Certain other statues of the pre-Khmer period, notably a magnificent image of the Hindu deity Hari-Hara in the museum at Phnom Penh, are distinguished by an almost Egyptian feeling for the sheer abstract mass and volume of the plastic form. The slightly unbalanced, almost momentary pose of the figure and the rhythmic articulation of parts and whole communicate to the statue a feeling of tense aliveness and imminent movement that is perhaps to be interpreted as an indication of the influence of the religious dance on the plastic arts in farther India.

R. MOULIN FROM EWING GALLOWAY

*The Buddhas of Wat Benchamabopitr, a temple in Bangkok, Siam*

The development of architecture in Cambodia, like the history of sculpture in this same region, reveals the evolution of a completely national style on a foundation of Indian origin. The earliest sanctuaries of the sixth and seventh centuries are isolated brick or laterite towers, each containing a single cella for the cult image. The towerlike structure is faintly reminiscent of the Indian *sikkhāra,* and certain details of the architectural decoration have close parallels in the Pallava architecture of southeast India. All the buildings of this period bear out the testimony of contemporary inscriptions to an intimate connection with the Pallava culture, the inheritor of Gupta civilization in southeast India.

**Classic Period.** The history of sculpture in Indochina and Siam continues with the establishment of the power of the Khmer people; it is marked by the development of an art that is distinctly national in style and iconography. The sculptors' realization of the cubic mass of the image is no less notable in the Early Classic statues of the ninth and tenth centuries than it was in the masterpieces of the pre-Khmer period. It seems almost certain that the stocky physical type seen in Buddhist and Hindu images alike is the reflection of a Khmer racial characteristic with no relation to any Indian canon of divine proportion. The same is probably true of the square, blocklike heads and of certain features, such as the enormously full and wide lips. The portraitlike character of many of the statues is due to the cult of the *deva-rāja* (god-king) in which the sovereign was regarded as an earthly manifestation of the deity. In the art of these centuries we may discern the evolution of what ultimately becomes a Khmer formula for representing the beatitude and inner serenity of the divinities: the eyelids are closed in reverie, and the lips are curled in a long, slow smile. This formula tends to assume the character of a rigid formalized mannerism in the last examples of Khmer sculpture that filled the great temple-tomb of Angkor Vat (twelfth century) and in the giant heads of Lokeśvara that ornament the thirteenth century shrine of the Bayon. An exactly parallel development seems to have taken place in Siam with the result that, except for certain local peculiarities, the statues carved at the Siamese capital of Lopburi are hardly to be distinguished from the contemporary sculpture of Angkor.

Although the earliest examples of relief sculpture in Cambodia show a dependence on motifs of Indian origin, it was not long before the native carvers displayed very marked stylistic and iconographical innovations of their own. The sculptors developed a technique of decorating the façades of buildings with continuous friezes of relief, which appear to have been carved directly on the face of the building after the blocks of the structure were already in place. The paneled reliefs that decorate the tenth-century palace of Phimeanakas at Angkor are a continuation of the classic Indian style of the Gupta period and show a feeling for action and dramatic narration that are purely indigenous. In its final development, the technique of the frieze assumes a definitely pictorial character, as may be illustrated by the carvings of Hindu epics that clothe the walls of the lower galleries of Angkor Vat like tapestries. In the carving of lintels and tympana, the Khmer sculptures reveal an exuberance of ornament and precision of carving that are as original as they are unparalleled in the art of the Orient.

The architecture of the Classic period, which begins with the consolidation of Khmer power under Jayavarman II in 802, is marked by the emergence of truly national characteristics in building: the isolated sanctuary is now constructed almost entirely of laterite and is placed on the summit of a stepped pyramid. This pyramid or *prasada* is a symbolical

architectural replica of the world mountain that supports the paradise of the gods. Such pyramidal foundations were used also for secular structures, as in the case of the palace of Phimeanakas in the first Khmer capital at Angkor. The palace itself was of wood and has long since vanished, but there are indications that during the Classic period the Cambodian architects began to imitate elements of native wooden architecture in stone. It could be said that the greatest Khmer contribution to architecture is in the development of the ground plan. Since the vault was never developed beyond the most primitive corbel stage, it was impossible for the Cambodian builders to cover large interior spaces; and so, when the need arose for larger and more complex sanctuaries, they met the problem by joining many small units into an integrated whole. The first step toward the final solution is to be seen at Banteiai Srei, where a number of stone towers are grouped around a temple courtyard. At Ta Keo the towers, each containing a single image cell, are elevated by an enormous pyramid of stone and are joined by galleries that completely girdle the perimeter of the platform.

The culmination of the Khmer genius in building is achieved in the great temple-tomb of Sūryavarman II (1112-1152), the world-famous monument of Angkor Vat. The monument is laid out on a rectangular plan surrounded by a moat nearly fifteen miles in circumference. The ground floor consists of a vast gallery nearly a mile in extent; an inner court on a higher level is reached by entrances on all four sides. In the center of this enclosure rises a mountainous pyramid, which supports a central tower 250 feet in height with smaller towers of the same form at the four corners. This temple marks the culmination of tendencies toward combining vertical and horizontal elements already detected in earlier building. Even in a gigantic structure like this, the vaulting of the separate elements is of the most primitive corbel type, reinforced by wooden beams hidden in the stone masonry. It is the cruciform plan with the arms joining the enclosing galleries that makes possible this new and grandiose ensemble composed of multiple small elements. Many tricks of illusionistic perspective are employed in the building in order to give greater scale to the central mass. The central tower originally contained a statue of the king in the form of the god Vishnu, and the subsidiary towers had statues of other forms of Vishnu in the likenesses of the king's ministers. The reliefs covering the ground floor gallery are partly historical and partly episodes from the Vishnu legend, which bore a resemblance to events from the life of Vishnu's earthly incarnation, Sūryavarman.

The last Khmer building of any size to be built was the temple of the Bayon, which came to be the center of the capital of Angkor Thom. In its final form, as completed by Jayavarman VII (1181-1201), the sanctuary is a temple-mountain raised above a cruciform plan enclosed within a square. The most striking feature of this monument consists in the giant faces of the Bodhisattava Lokeśvara carved on the four faces of each tower, which were intended magically to proclaim the power of this divinity over the four quarters of the world. The temple was the magic center of the Cambodian realm and the shrine of the sovereign as the earthly avatar of Lokeśvara. The entire edifice, from the statuelike towers to the walls of the outer galleries, is literally covered with sculpture. This marks the culmination of a tendency—already threatened at Angkor Vat—in which the carving has completely engulfed the architecture itself. The whole building has a baroque, unstable quality, which is echoed in the very hasty and unsound construction that marks the end and exhaustion of a great civilization.

BURTON HOLMES FROM EWING GALLOWAY

*Throne Hall, a magnificent building of Occidental design, was the scene of the coronation of Prajadhipok, monarch of Siam, in Bangkok.*

**Modern Period.** The Siamese conquest of Angkor in the fifteenth century marked the end of the Khmer civilization. The later history of architecture here is marked by the disappearance of monumental concepts of the Classic period, a reversion to wooden construction, and, above all, an assimilation of elements of design from many foreign sources: Chinese, Burmese, and even European. Modern Siamese architecture is a baroque conglomerate of traditional and foreign forms, characterized by the brilliant polychromatic decoration of the buildings in glass and porcelain mosaic.

## JAVA

The great period of Javanese art comes in the eighth and ninth centuries of the Christian Era, when Java and Sumatra were under the rule of the Śailendra kings, whose conquest of Indonesia established Mahāyāna Buddhism as the religion of the realm. There are, to be sure, some monuments of Hindu sculpture and architecture testifying to earlier Hindu colonization, but none can compare to the great temple of Barobudur that rises on the plains of south central Java. This sanctuary is really a rounded hill, terraced and clothed in stone, consisting of five terraces on a rectangular plan; above these are three round platforms on which are seventy-two bell-shaped latticed stupas and a sealed terminal stupa at the very summit of the monument; a ninth story is present, though unseen, in the form of a hidden basement. The total mass is a dome cut by galleries, which disappear from view if the monument is looked at in profile, when the outline becomes that of a stupa. In other words, we have a pyramid inside a stupa, an arrangement intended to reproduce symbolically in architecture the Indian concept of the sky as a

solid bowl covering the world-mountain Meru. The temple is a *mandala* or magic diagram of the material and spiritual worlds manifested in the universal Buddha Vairocana, whose image was enshrined in the closed bell-shaped stupa at the top of the monument. The subject matter of the reliefs of the successive galleries begins with representations from the World of Desire, in the lower stories, and culminates, in the upper corridors, in the representation of the spiritual world without form and action. The symbolism of the monument is completed by the statues of the mystic Buddhas in latticed stupas and by the Buddhas of the four directions that fill the niches on the four sides of the building. The style of the reliefs of the galleries, echoing the hieratic progression of their subject matter, begins with a direct and even naturalistic treatment of subjects from the World of Desire and progresses to a completely abstract diagrammatic representation of the realms of the mystic Buddhas in the uppermost corridor. The Buddha images may be compared with the masterpieces of Gupta art in India: they represent such a beautiful realization of plastic mass and breathing life, combined with a crystalline simplicity of expression, that they rank among the greatest expressions of sculptural genius in the world.

B. Ro.

**SOUTHEND-ON-SEA,** a county and parliamentary borough in Essex, England, 42 mi. east of London. Picturesquely situated on the Essex bank of the River Thames, it is a seaport and one of the nearest popular seaside resorts to London. Southend-on-Sea, incorporated in 1892, was made a county borough in 1914 and a parliamentary borough in 1918. Interesting buildings include a thirteenth-century castle and, near by, the Cranham Church, where General James Edward Oglethorpe, founder of Georgia, is buried. Manufactures include paint, pharmaceuticals, electrical appliances, and metal products. The town returns two members to Parliament. Pop. 1954, 151,500. A. W.

**SOUTHERN ALPS,** a picturesque chain of mountains forming the mountain backbone of South Island, New Zealand. The chain parallels the longitudinal axis of the island, and lies somewhat nearer the west coast than the east. Narrowing in the center to a single range of mountains, it fans out in the northeastern and southwestern parts of the island like the spokes of a wheel, forming several diverging ranges between which are deeply incised valleys and, near the coast, small triangular or crescent-shaped patches of alluvial lowland. The chain contains more than 220 named peaks over 7,500 ft. high, culminating in Mount Cook, which rises to 12,349 ft. The central part of the chain, the Mount Cook Range, contains many glaciers. The largest of these, the Tasman Glacier, is about 20 mi. long and over a mile wide. Other notable glaciers include the Mueller, Hooker, Godley, and Murchison, which grind their way slowly down the eastern slopes and terminate some 4,000 ft. above sea level; and the Fox and Franz Josef glaciers on the western slopes of the chain, which descend much more steeply and reach to within 700 ft. of sea level. The Southern Alps are important as a tourist attraction, as a source of irrigation water, and as a wild-life refuge and game preserve. Some lumbering and mining is carried on locally on their lower slopes and in the adjacent foothill belt. R. G. B.

**SOUTHERN CALIFORNIA, UNIVERSITY OF,** an accredited, coeducational, privately-controlled institution occupying a 50-acre campus about 3 mi. from the business section of Los Angeles, Calif. The charter was granted in 1880, when first instruction was given in the College of Letters, Arts, and Sciences. The numerous other divisions of the university were added as follows: School of Music, 1887; Graduate School of Religion, 1887; School of Law, 1896; College of Dentistry, 1897; College of Pharmacy, 1905; Summer Session, 1912; School of Education, 1918; Graduate School, 1920; University College, 1924; Los Angeles University of International Relations, affiliated 1924; College of Architecture, 1925; College of Engineering, 1927; School of Medicine, 1928; School of Public Administration, 1929; School of Philosophy, 1929; School of Journalism, 1933; Graduate School of Library Science, 1936; Allen Hancock Foundation for Scientific Research, 1938; School of Nursing, affiliated 1941; College of Aeronautics, 1945; and Institute of the Arts, 1946. The local chapter of Phi Beta Kappa was organized in 1929.

Degrees offered include the bachelor's degree in the various curricula, the LL.B., the B.S. in library science, the M.A., the Ph.D., the D.D.S., and the M.D. A new degree, Doctor of Public Administration, offered for the first time in 1950, carries requirements that are comparable to those of the Ph.D.; its three-year program includes work in government organization, management, administrative analysis, personnel, and financial administration.

Scholarship assistance is available; however, most of it is restricted to residents of California. A fund is available for student loans. Opportunities for self-help enable approximately one third of the students to earn part of their expenses. Residence halls and fraternity houses offer living facilities to a limited number of students. All lower-division students must live in residence halls or in approved houses. *For statistics see* COLLEGES AND UNIVERSITIES. J. R. To.

**SOUTHERN CROSS.** *See* CRUX.

**SOUTHERNE, THOMAS** [sʌ′thərn] (1660-1746), English dramatist, was born at Oxmantown, near Dublin, in 1660. His first play, *The Loyal Brother* (1682), was a heroic tragedy. His more popular plays—*The Fatal Marriage* (1694) and *Oroonoko* (1695), both based on novels by Aphra Behn—mingle the heroic and Shakespearean tragedy with the sentimental and pathetic, in accordance with the newer dramatic trend. He died on May 22, 1746, and is buried in St. Margaret's Church in Westminster.

E. L. A.

**SOUTHERN LIGHTS.** *See* AURORA BOREALIS AND AURORA AUSTRALIS.

**SOUTHERN METHODIST UNIVERSITY,** an accredited, coeducational university controlled by the Methodist Church. It is located on a 133-acre campus in University Park, a residential area near Dallas, Texas. The charter was granted in 1911 and first instruction was given in 1915. The original organization was made up of the College of Arts and Sciences, the Graduate School, the Perkins School of Theology, and the School of Music. The School of Law and the School of Engineering were established in 1925, and the School of Business Administration in 1941.

The degrees offered include the A.B., the B.B.A., the B.S. in mechanical, civil, and electrical engineering, the B.D., the B.Mus., the LL.B., the M.B.A., and the M.A. Some engineering programs have co-operative work-and-study courses which delay the degree one year.

Many graduate fellowships and undergraduate scholarships are available and there is a large loan fund. Opportunities for self-help enable approximately half of the students to earn part of their expenses. Dormitories and dining halls are

provided. The men's fraternity houses provide living quarters for their members. *For statistics see* COLLEGES AND UNIVERSITIES. J. R. To.

**SOUTHERN RHODESIA.** *See* RHODESIA.

**SOUTHERN UNIVERSITY AND AGRICULTURAL AND MECHANICAL COLLEGE,** an accredited, coeducational, state-controlled land-grant university for Negroes, occupying a campus of over 500 acres in Scotlandville, La., near Baton Rouge. It was chartered in 1880 as Southern University by the general assembly of Louisiana at New Orleans. First instruction was given in 1883. The name was changed to the present form and the college moved to Scotlandville in 1914. The various divisions of the college were founded as follows: arts and sciences, 1883; agricultural, home economics, and mechanic arts, 1914; physical education, 1936; commercial education, 1937; music, 1938; law, 1947. The degrees offered include the A.B. and the B.S. in liberal arts, the B.S. in business, the B.S. in agriculture, the A.B. and the B.S. in education, the B.S. in nursery school education, animal husbandry, health and physical education, mechanic arts, and foods and nutrition.

Scholarship aid in the form of small stipends is available. Opportunities for self-help enable some of the students to earn part of their expenses. Dormitories and dining halls are provided. The sororities and fraternities do not have houses for their members. *For statistics see* COLLEGES AND UNIVERSITIES. J. R. To.

**SOUTH EUCLID** [yu'klɪd], a city in Cuyahoga County, in northeastern Ohio, about 9 mi. east of Cleveland, of which it is a residential suburb. Founded in 1917 and incorporated as a city in 1940, South Euclid is administered by a mayor and council. It is the seat of Notre Dame College for women and the Rainbow Hospital for crippled children. Pop. 1950, 15,432.

**SOUTHEY, ROBERT** [sau'thi; sʌ'thi] (1774-1843), English poet, historian, and man of letters, was born at Bristol, Aug. 12, 1774, coming from a line of respectable and undistinguished yeomen. He spent much of his childhood with an aunt who was despotic and whimsical, but in a small way was a patroness of the drama. After desultory schooling, supplemented by his own reading and by experiments with plays and poems, he matriculated at Oxford to study for the Church, later for medicine, and still later for law; but none of these careers satisfied him. Meanwhile, he met Samuel Taylor Coleridge and Charles Lamb, and continued his writing, which was now fired with an enthusiasm for the ideals of the French Revolution. After marrying Edith Fricker, Mrs. Coleridge's sister, and deciding upon a literary life, Southey settled with Coleridge in 1803 at Keswick, in the Lake District, and almost at once assumed the support of both families. Thereafter his life was devoted to a daily regimen of writing poetry, reviewing, and collecting materials for histories and biographies. He was named Poet Laureate in 1813, but he refused all other public recognition and appointments, the better to pursue writing. In 1839, after the death of his first wife, he married Caroline Anne Bowles. He died at Keswick, March 21, 1843, worn out in mind and body.

In his own day, Southey's long epic poems received favorable notice from Scott, Wordsworth, and Coleridge, and Southey placed his hopes of permanent fame on these. However, the shorter and less pretentious *Bishop Hatto, Battle of Blenheim,* and *His Books* have retained their popularity better than *Thalaba, Roderick,* and other poems of an epic character. Whatever the verdict on Southey's poetry may be, the merit of his biographies, histories, and reviews is undeniable, for his prose style is perspicuous and free of mannerisms, an ideal instrument for his thoughts. His histories of Portugal and Brazil, though admirable in their day, have been superseded; his *Life of Nelson* is delightful and sometimes masterful in its narrative skill, and his *Life of Wesley* closely rivals

ROBERT SOUTHEY

FROM AN ENGRAVING BY H. B. HALL & SONS

COURTESY OF THE NEW YORK PUBLIC LIBRARY

it. *The Doctor,* a curious miscellany, displays his humor, a playful, restrained whimsicality. Perhaps the best view of Southey is to be gained, however, through his correspondence. There his morality and industry are displayed, and, in addition, the engaging qualities of smiling earnestness and modest and tolerant faith. R. G. Bo.

**SOUTH GATE,** an industrial city in southern California, located 7 mi. south of Los Angeles. South Gate, which was incorporated as a city in 1923, experienced a large increase in population between 1940 and 1947, attributable chiefly to the World War II concentration of industry in the Los Angeles area. The varied factory output includes automobiles, rubber tires, concrete, steel, chemicals, linoleum, screws, and airplane parts. Transportation is provided by the Pacific Electric, the Southern Pacific, and the Union Pacific railroads. Pop. 1950, 51,116.

**SOUTH GEORGIA ISLAND,** an island in the South Atlantic Ocean 800 mi. southeast of the Falkland Islands, of which it is a dependency. South Georgia Island is the base for the principal whaling industry of the world, and five whaling factories render the oils and convert bones and flesh into fertilizer. Most of the island's 1,450 sq. mi. are occupied by high snow-covered mountains and glacier-filled valleys. Grytviken Harbor is the principal settlement. The permanent population of 750 is composed chiefly of the Norwegian and Swedish crews of the whaling vessels which operate in Antarctic waters between October and March. Supplies are obtained and whale oil exported through Port Stanley in the Falklands. *See also* FALKLAND ISLANDS. P. E. J.

**SOUTH HADLEY,** a town in west central Massachusetts, situated in Hampshire Co., on the east bank of the Connecticut River, 12 mi. north of Springfield, in an area of diversified agriculture. Founded about 1659 as a part of the town of Hadley, it was incorporated as a separate town about

1775. The local government is the representative-town-meeting type. South Hadley is the seat of Mount Holyoke College for women, established in 1837. Transportation is provided by the New York, New Haven and Hartford and the Boston and Maine railroads at Holyoke, across the river. Pop. 1950 (town) 10,145; (village) 2,446.

**SOUTH HOLLAND,** a province in the west central Netherlands. South Holland, which has an area of 1,130 sq. mi., may be divided into a northern section, the mainland, and a southern section, consisting of a number of islands. It is bounded on the north by North Holland, on the east by Utrecht and Gelderland, on the south by North Brabant and Zeeland, and on the west by the North Sea. Except for the dunes on the west coast, most of the province is situated below sea level and must be protected by dikes. The Rijn (Rhine) River, which flows through South Holland, has been canalized, and there are considerable areas of reclaimed polder land. Other waterways include the Lek River and numerous canals.

General farming, cattle raising, and the cultivation of flower bulbs are carried on extensively. The mainland is mostly grassland suitable for pasturing, and the farmlands of the islands are used mostly for crop cultivation. The leading industrial cities are Rotterdam, Delft, Gouda, Schiedam, and Leiden, where there are sugar refineries, distilleries, brickworks, shipbuilding yards, machine shops, and petroleum refineries, vegetable-oil, margarine, and clothing factories, and furniture and ceramics plants. At Rotterdam is held the largest cattle market in the Netherlands, and cheese markets are held in Bodegraven, Woerden, Gouda, Leiden, and Oudewater. Rotterdam is the nation's greatest center of maritime and island shipping and is the port of transshipment for the transit trade up the Rhine to Germany. The capital of the province is The Hague, which is also the seat of the national government. Prominent seaside resorts are Katwijk aan Zee, Noordwijk-Binnen, Hoek van Holland, and Oostvoorne. Leiden has a state university which was founded in 1575; in Delft is the State Technical College; and the Netherlands Institute of Economics is in Rotterdam. Pop. 1952, 2,453,465. T. R.

**SOUTHINGTON** [sʌ′thɪŋtən], a town, including a village of the same name, in central Connecticut, situated in Hartford Co., 20 mi. north of New Haven, in an agricultural area marked by fruit, dairy, and poultry farms. Southington was incorporated as a town in 1779, and its government is administered by a mayor and council. Features of special interest are the Jonathan Root Tavern, which has a Dutch doorway reported to date from 1720; the Curtis-Robinson home, built about 1766; the collection of period furniture and historical relics in the library annex; and the Rogers orchards, with some 4,500 peach trees and 6,000 apple trees. Chief manufactures are hardware, tools, paper boxes, furniture, and airplane, automobile, and radio parts. Pop. 1950 (town) 13,061; (village) 5,955.

**SOUTH MILWAUKEE** [mɪlwɔ′ki], a city in Milwaukee Co., in southeastern Wisconsin, situated on the west shore of Lake Michigan at the mouth of Oak Creek, 10 mi. south of Milwaukee. Incorporated in 1897, the city is governed by a mayor and council. It is a manufacturing community, with transportation provided by the Chicago and North Western Railroad. The factory output includes malleable castings, excavating machinery, metal, tile, wood products, electrical devices, and shoes. Pop. 1950, 12,855.

**SOUTH OSSETIAN AUTONOMOUS OBLAST** [ɒsi′shiə], an administrative subdivision of the Georgian Soviet Socialist Republic, Union of Soviet Socialist Republics, formed in 1922. It abuts the North Ossetian Autonomous Soviet Socialist Republic on the north, but elsewhere is embraced by the Tbilisi region. Situated on the slopes of the main Caucasus Range, the 1,500 sq. mi. of the oblast constitute a rugged, forested land in which the people pasture their cattle on the highlands or in the valleys, according to the season. The cultivation of maize in intermontane basins, the growing of fruits in the temperate zone, and lumbering are other economic pursuits. Although most of the people are of the same Iranian ethnic stock as their North Ossetian neighbors, they distinguish themselves by using the name Tualte. Georgians constitute 27 per cent of the populace, while almost 70 per cent are Ossetians. Stalinir, a small mountain town, is the administrative center of the oblast. Pop. (est. 1954), 120,000. W. S. V.

**SOUTH PASADENA** [pasədi′nə], a residential city in southern California, part of South Pasadena township, situated in Los Angeles Co., contiguous with Los Angeles, of which it is a suburb. Founded in 1870, South Pasadena was incorporated as a city in 1888. It is governed by a council and a city manager. A feature of special interest in the vicinity is a butterfly farm. Transportation is provided by the Pacific Electric, the Southern Pacific, and the Atchison, Topeka and Santa Fe railroads. Local manufactures include scientific instruments, gas valves, fluid pumps, dresses, rubber stamps, radio equipment, drugs, and electric appliances. Pop. 1950, 16,935.

**SOUTH PLAINFIELD,** a residential borough in northeastern New Jersey, situated in Middlesex Co., contiguous with Plainfield, 30 mi. northeast of Trenton, and 27 mi. southwest of New York City. South Plainfield was incorporated as a borough in 1926. It is administered by a mayor and council. Transportation is supplied by the Lehigh Valley Railroad. Pop. 1950, 8,008.

**SOUTH POLE.** *See* Polar Regions; Seasons (*Change of Seasons*).

**SOUTHPORT,** a county and parliamentary borough and a popular vacation and health resort, in Lancashire, England, situated about 18 mi. north of Liverpool on the Irish Sea. Southport, incorporated in 1867, was created a county borough in 1905 and a parliamentary borough in 1918. Among its attractions are a fine beach used for automobile speed tests, a long seaside promenade, a marine park, and botanical gardens. Pop. 1954, 82,980. A. W.

**SOUTH PORTLAND,** a city in southern Maine, on the Atlantic coast, in Cumberland Co., situated on Fore River, opposite Portland, with which it is connected by bridges. Originally a part of Cape Elizabeth, South Portland was set off and incorporated as an independent community in 1895. It shares Portland's transportation facilities. Industrial establishments include shipyards, copper works, rolling mills, a nylon plant, and a wire-stripping plant. Pop. 1950, 21,866.

**SOUTH RIVER,** a borough in northeastern New Jersey, situated in Middlesex Co., on South River, a branch of the Raritan River, 7 mi. southwest of Perth Amboy. In the heart of the sand and clay region of the state, South River is an important center for the production of bricks and ceramic

objects. Other manufactures include clothing and cigars. The Raritan River Railroad furnishes freight service. Founded by Samuel Willett in 1720, the borough was incorporated in 1898. A mayor and council administer the community. Pop. 1950, 11,308.

**SOUTH ST. PAUL,** a city in the eastern portion of Minnesota, in Dakota Co., on the Mississippi River, 4 mi. south of St. Paul. One of the first settlements in the state and originally called Koposia, South St. Paul was incorporated as a city in 1887. A mayor and city council govern the community. An important shipping and wholesale distribution point, the city has rail facilities furnished by eight railroads, only one of which, the Chicago Great Western, provides passenger service. Stockyards and meat-packing plants constitute the chief industrial establishments. Pop. 1950, 15,909.

**SOUTH SALT LAKE,** a town in north central Utah, situated in Salt Lake Co., 3 mi. south of Salt Lake City, of which it is a suburb. The region is rich in natural resources, including silver, copper, zinc, lead, iron ore, natural gas, coal, phosphate, gilsonite, and timber. The local government is the council-manager type. Pop. 1950, 7,704.

**SOUTH SAN FRANCISCO,** an industrial city in western California, in San Mateo Co. It is situated on San Francisco Bay, about 5 mi. south of San Francisco. Founded in 1896, it was incorporated as a city in 1908. The city's chief employers are the steel, shipbuilding, and meat-packing industries and the air lines at the near-by airport. Pop. 1950, 19,351.

**SOUTH SEA BUBBLE,** the name given to a large-scale financial venture in England, which commenced with the formation in 1711 of the South Sea Company, with a monopoly of trade to Spanish America, and ended in financial scandal and disaster for many stockholders. The original South Sea Company was at first unwisely and afterwards dishonestly managed. When in 1713 England received the Asiento, or right to sell slaves in the Spanish possessions in America, this right was handed over to the company, which rapidly became highly successful. In 1720 the company underwrote the English national debt, on a promise of 5 per cent interest from the government. Its shares immediately rose to ten times their value, speculation ran wild, and all sorts of joint-stock companies, lunatic, fraudulent, or merely optimistic, were formed. A government attempt to halt speculation caused a fall in the price of the stock; this was followed by general distrust, and by November 1720 the Bubble had burst, ruining thousands of families. Almost all the wealthy persons in the kingdom had become speculators, and members of the government were found to be involved in the manipulations of the company. As the result of a parliamentary inquiry, John Aislabie, Chancellor of the Exchequer, and several members of Parliament were expelled in 1721, and the estates of the directors were seized and sold. The company was reorganized on a sounder basis and remained in existence until 1807. C. W. D.

**SOUTH SEA ISLANDS.** *See* Melanesia; Micronesia; Oceania; Pacific Islands; Polynesia.

**SOUTH SHIELDS,** a county and parliamentary borough, seaport, and resort in Durham County in northeastern England. The town lies on the North Sea at the south side of the mouth of the River Tyne, 9 mi. east of Newcastle-on-Tyne, and adjacent to the industrial town of Jarrow. A major port of the coal and steel areas, South Shields is famous for shipbuilding. Coal exporting, formerly a major activity, has diminished considerably, while the manufacture of machines and steel goods has increased.

The town is contained within a sharp bend of the Tyne, and the beach resort at Marsden Bay at the end of Hadrian's Wall attracts large numbers of visitors. Originally a Roman station, Ostia Vedra, the town was founded by the prior of Durham convent in 1245; its present name, derived from *shielings,* meaning sheds, attests to its early fishing industry. Pop. 1952, 107,100. B. Su.

**SOUTH SIOUX CITY** [su′], a city in northeast Nebraska, in Dakota Co., situated on the Nebraska-Iowa boundary, on the Missouri River, 85 mi. northwest of Omaha and 2 mi. southwest of Sioux City, Iowa. Founded and incorporated as a city in 1887, South Sioux City is administered by a mayor and city council. The city is a trading center for a farming region. Local industries include an alfalfa dehydrating plant, a furniture factory, a poultry and egg-processing plant, and a creamery. Pop. 1950, 5,557.

**SOUTH VICTORIA LAND.** *See* Victoria Land.

**SOUTHWELL, ROBERT** [sau′thwəl] (c. 1561-1595), English Jesuit priest and poet, was born at Horsham St. Faith's, Norfolk. He was educated at Douay and Rome and, despite Elizabeth's orders expelling Catholic priests from the realm, returned to England in 1586. In 1589 he became chaplain to the Countess of Arundel, and during his chaplaincy he composed several religious tracts, among them his *Epistle of Comfort.* In 1592 he was arrested while on his way to celebrate Mass, cast into prison, tortured, and finally tried and executed at Tyburn on Feb. 21, 1595. Southwell composed many of his poems while in prison, among them *St. Peter's Complaint* (1595), *Maeoniae* (1595), and *A Foure fould Meditation of the foure last things* (1606). The *Meditation* contains his best-known poem, *The Burning Babe,* of which Ben Jonson is quoted as having said, "So he had written that piece of Southwell's, *The Burning Babe,* he would have been content to destroy many of his." C. D.

**SOUTH-WEST AFRICA,** a mandated territory of the Union of South Africa, formerly a German colony. Facing the South Atlantic between the Cunene River in the north and the Orange River in the south, it is bounded on the north by Angola and Northern Rhodesia, on the east by Bechuanaland, and on the southeast and south by the Union of South Africa. The area of the territory is 317,725 sq. mile; the enclave of Walvis Bay (374 sq. mi.), which belongs to Cape of Good Hope province, is administered as an integral part of South-West Africa.

**Geographical Characteristics.** The distance from north to south is about 800 mi. and from west to east, about 400 mi. A narrow panhandle known as the Caprivi Concession extends nearly 300 mi. due east from the northeast corner of the territory. Acquired by Germany in 1893, this strip gives South-West Africa contact with the Zambezi River, but the eastern end is so inaccessible from Windhoek, the capital, that it has to be administered from Praetoria, Union of South Africa.

Nearly all the territory is about 4,000 ft. above sea level, a vast plateau divided by broken and ragged ranges 60 to 100 mi. inland which extend almost the whole length of the

territory. Some crests are over 8,000 ft. high. West of these ranges is a coastal belt of sterile sand dunes, the Namib Desert, extending from the Orange River to beyond the Ugab River north of Walvis Bay. In the southern part of the territory, drainage is south toward the Orange, the intermittent rivers following highland valleys. Farther north, short seasonal rivers to the west of the highlands flow into the Atlantic; those to the east eventually lose themselves in the Kalahari Desert of Bechuanaland. The only perennial rivers are those forming parts of the boundary of the mandate—the Zambezi, Cuando, Okovanggo, and Cunene in the north, and the Orange in the south.

*Climate.* A line along the highlands from the Orange to the Cunene separates the western region of winter rains from the eastern summer rains. Annual precipitation varies with latitude from about 6 in. along the Orange to about 25 in. in the northeast. Along the southern part of the coast the rainfall is sometimes under 1 in., and this, coupled with the sterility of the soil, creates the coastal Namib Desert. Although neither of these conditions prevails in the highlands or farther east, the increasing heat of inland summers, and the fact that in the east the rainfall comes in the summer months, results in greater evaporation. In fact, except in the north, the Kalahari Desert stretches from Bechuanaland into the eastern section of South-West Africa.

**Population.** According to the census of 1951, the total population was 414,601, including about 48,000 Europeans. Windhoeck in the central highlands, the capital and largest city, had about 29,000 inhabitants in 1951, about 11,000 of whom were Europeans. Because of greater rainfall and heavier vegetation in the far north, there is a greater density of population in that region. The Ovampo, those of Kaffir race and Bantu speech in this area, number about 190,000. They are agriculturalists as well as herdsmen. To the northeast, including the Caprivi Concession, about 15,000 primitive bushmen live wholly by hunting. To the south of the Ovampo are the Damara, a group of people which includes the Hill Damara or Berg Damara and the Herero. The Hill Damara, numbering about 30,000, are of Kaffir stock with some admixture of Hottentot, but their speech is predominantly Hottentot. Scattered widely along the coastal side of the highlands the Herero number about 28,000, speak a Bantu dialect, and are of Negro origin. To the south the predominant racial group is the Hottentot. Although of purer blood than the Hottentot of the Cape, they are obviously of mixed European, Kaffir, and basic Hottentot origin. Their total number is thought to be about 40,000. Finally, there are about 5,000 Griqua or Bastards, of extremely mixed antecedents, centered in the Rehoboth district south of Windhoek. About half the residents of European stock live in towns along the railway, and more than half speak Afrikaans.

*This grotesquely shaped, rock-hard hill in the wilds of South-West Africa is built by great masses of termites.*

**Government.** The administrator of South-West Africa is appointed by and responsible to the Union government. There is a legislative assembly, consisting of 18 members elected by the registered voters of the territory. An executive committee is composed of the administrator and 4 other members chosen from the legislative assembly. In 1949 the status of South-West Africa was changed, when the territory was given the right to elect 6 representatives to South Africa's House of Assembly and to have 4 senators in the Union Senate. Since the United Nations in 1946 refused to accede to the Union's request that the mandate be fully integrated with the Union, the Union has in turn refused to admit the right of the United Nations to make the mandate a trust territory under the UN Trusteeship Council.

There is a chief native commissioner under whom 17 district commissioners operate in administering local government.

**Finance.** The currency is the Union pound, which is at par with the British pound. In September 1949 it was devalued from $ (U.S.)4.03 to $2.80. Revenues in the fiscal year 1953-1954 amounted to £5,750,000 and expenditures to £5,746,000.

**Education.** The government runs only a few schools for native children; however, state aid is extended to most of the 268 schools operated by missions and other agencies. In 1951-1952 government expenditures for education were £629,515, including £496,263 for European children and £133,252 for African children and those of mixed race.

**Economic Activities.** *Livestock.* Karakul sheep, cattle, and goats are the principal kinds of livestock, possession of which is the chief sign of wealth among the native peoples. Except where conditions are favorable to crops, farms in such a dry country are naturally of great size, varying from 12,000 to 50,000 acres. Practically all the crops are either for stock feed or for local human consumption.

*Mining.* Diamonds, copper, and lead are the most important minerals. Diamonds, first discovered to the north of the Orange in 1908, have been found in alluvial deposits along the coast for about 300 mi. They are mostly of gem quality, but decrease in size toward the north. Lüderitz is the chief diamond center. Copper and lead occur mainly in the north in the Grootfontein region and particularly at Tsumeb. In 1952, diamond production was valued at £10,500,000, lead-copper concentrates at £7,800,000, and zinc and lead-vanadium concentrates at much smaller amounts. Other less important mineral products include tin, salt, and semi-precious stones.

**Commerce.** More than half of the imports come from

the provinces of the Union, but less than one third of the exports go to the provinces. The total value of imports in 1953 was £24,069,726, and of exports, £35,178,261. Imports cover a wide variety of goods, especially manufactures. In 1952 the value of exported karakul skins was £5,641,198; diamonds, £10,688,783; and live animals for slaughter, £2,982,000. Lesser amounts of lead, copper, butter, and fish were also exported. Such manufacturing as exists is largely animal food processing (butter and cheese) at Windhoek, Walvis Bay, and Lüderitz. The territory has had a customs union with South Africa since 1915, and receives a prorated share of the combined customs revenue.

*Transportation.* The railway system is an integral part of the government-owned South African Railways. Within the territory are 1,529 mi. of broad-gauge track, 350 mi. of narrow-gauge track, and 3,283 mi. of railway-operated motor services. Consequently, there are not only railroad connections among the major economic sections of the country but also overland routes to Angola and Bechuanaland. Windhoek is connected with both Kimberley and Capetown by air services. Walvis Bay is the most important port, handling about 95 per cent of the territory's foreign exports and a substantial part of the coastal trade. It is 710 mi. by sea from Capetown, but 1,383 mi. by rail.

**History.** In 1486 Bartholomeu Dias put in at the port now known as Lüderitz, which he named Angra Pequena. However, for four centuries neither the Portuguese nor later arrivals found a use for this inhospitable shore. German Protestant missionaries began work in the territory in 1805, working their way north from the Orange River. Great Britain annexed some of the coastal islands in the 1860's and the Walvis Bay area in 1878. In 1883 a Bremen merchant, F. A. C. Lüderitz, purchased land in the vicinity of Angra Pequena from a local chief. The territory so acquired was annexed by Germany in the following year, and in 1885 it was granted to a German colonization society. An expensive war with the Hottentots ensued, and the company was happy to relinquish its claim in 1892. By the following year the Hottentots were pacified. Also in 1893, Caprivi, the German chancellor, negotiated a boundary extension, including the Caprivi Concession, which gave access to the Zambezi River and cut off Southern Rhodesia from contact with Angola. In 1904 a long and bitter struggle began between the Germans and the Herero. By 1908 this Bantu nation was decisively beaten and its tribal system largely obliterated. In the same year, diamonds were discovered just to the north of the Orange River.

Attacked by Union forces at the outbreak of World War I, the Germans surrendered in 1915, and at the end of the war German Southwest Africa was assigned to the Union under a mandate of the League of Nations. In 1925 the Legislative Assembly was established.

After World War II, the Union of South Africa proposed to the UN General Assembly that South-West Africa be incorporated into the Union, arguing that the territory bordered on the Union, that it was economically unable to support itself, that it was sparsely populated, and that a majority of its inhabitants desired incorporation. The General Assembly, however, recommended that the territory be placed under the United Nation's international trusteeship system. Refusing to take this step, South Africa discontinued making reports to the United Nations on its administration of the mandate and in 1949 passed legislation giving South-West Africa representation in the Union Parliament similar to that of a province. The General Assembly then asked the International Court of Justice for an advisory opinion on the territory's legal status. In July 1950 the court issued an opinion with four main conclusions: that South Africa is not obliged to place the territory under trusteeship; that the territory is still under mandate; that the Union is still bound by the mandate's provisions, including the obligation to submit reports on administration; and that the Union cannot change the territory's status without United Nation consent. Despite this opinion, the issue remained deadlocked. W. M. W.

*Laundresses of the Herero tribe of Southwest Africa wear quaint printed calico gowns and carry their flat-irons on their heads.*

**SOUTHWESTERN AT MEMPHIS,** an accredited, coeducational, Presbyterian college of arts and sciences occupying 117 acres in residential Memphis, Tenn. Established by the Masonic Grand Lodge of Tennessee as Montgomery Masonic College at Clarksville in 1848, it was transferred to the control of the Presbyterian Church in 1855 and the name was changed to Stewart College. Twenty years later the name was changed to Southwestern Presbyterian University. After the college moved to Memphis in 1925 the present name was adopted.

The degrees offered are the A.B., the B.S., and the B.Mus. The courses in music are given under co-operative arrangements with the Memphis College of Music. Scholarships, work opportunities, and student loans are available. Residence halls are provided for men and women. *For statistics see* COLLEGES AND UNIVERSITIES. J. R. To.

**SOUTHWESTERN COLLEGE,** an accredited, coeducational, privately controlled institution of arts and sciences affiliated with the Central Kansas Conference of the Methodist Church. It is located on a 36-acre campus in Winfield, Kan. The college was founded in 1885 and first instruction was given in 1886. The degrees offered are the A.B. and the B.Mus. A generous undergraduate scholarship program

is in effect, with no residence restrictions. A student loan fund is available. There is also some opportunity for self-help. Residence halls are provided for men and women. *For statistics see* COLLEGES AND UNIVERSITIES. J. R. To.

**SOUTHWESTERN LOUISIANA INSTITUTE,** an accredited, coeducational, state-controlled college of arts and sciences, teachers college, and technological school occupying 600 acres in the city of Lafayette, La. It was established as the Southwestern Louisiana Industrial Institute in 1898 and opened for instruction in 1901. College rank was attained in 1918, and the name was changed to the present form in 1921. The teacher-training department, founded in 1912, developed into a four-year teachers college, under the name of the College of Education, in 1918. The College of Agriculture was founded in 1938 and the College of Engineering in 1939. The Industrial Arts Department and the Vocational Agriculture Department were established in 1946.

The degrees offered include the A.B., the B.S., the B.S. in engineering and in agriculture, and the A.B. and the B.S. in education. Scholarships are awarded in varying amounts, on the basis of work, honor, or legislative grants. There is also a loan fund. Students from outside the city must live in dormitories, with close relatives, or in approved houses. *For statistics see* COLLEGES AND UNIVERSITIES. J. R. To.

**SOUTHWESTERN UNIVERSITY,** an accredited, coeducational institution of arts, sciences, and fine arts controlled by the Methodist Church, at Georgetown, Tex. It was started in 1873 as an amalgamation of four institutions: Ruterville College (1840), Wesleyan College (1844), McKenzie College (1848), and Soule University (1856). It merged with Blinn Memorial College in 1932. In addition to the College of Arts and Sciences and the College of Fine Arts at Georgetown, the university operates junior colleges at Tehuacana and Weatherford and the Daniel Baker College at Brownwood. The university occupies a total of 645 acres of land. The degrees offered include the A.B., the B.S., the B.B.A., the B.F.A., and the M.A.

Students from outside the city must live in dormitories or in approved houses. Fraternity members may live in their houses; the sororities do not provide living accommodations for their members. Scholarship and student loan aid is generous. Opportunities for self-help enable many of the students to earn part of their expenses. *For statistics see* COLLEGES AND UNIVERSITIES. J. R. To.

**SOUTH WILLIAMSPORT,** a borough in north central Pennsylvania, situated in Lycoming Co., on the south bank of the west branch of the Susquehanna River, opposite Williamsport, 67 mi. north of Harrisburg. The borough is administered by a mayor and city council. The borough was formed from a combination of two previous settlements, Bootstown and Rocktown. Transportation is supplied by the Pennsylvania Railroad. Pop. 1950, 6,364.

**SOUTINE, CHAIM** [su'ti'n] (1894-1943), French painter, was born in 1894 in Smilovitchi, a city in a portion of Russia that was later to become Lithuania. At the age of fourteen, he went to Vilna where he studied at the Academy of Fine Arts. In 1911 he took up residence in Paris, studying at the Atelier Cormon and living in extreme poverty in a Montparnasse studio shared with Amedeo Modigliani. The two painters enjoyed for a time the patronage of Borowski and Paul Guillaume, but after the death of Modigliani, Soutine went to the Midi. He painted at Ceret from 1920 to 1923 and later spent two years painting at Cagnes (1925-1926). It was during the 1920's that Soutine came to prominence as one of the exponents of expressionism, and his celebrity persisted through the 1930's, when his work was known especially for its unconventionality, its violence, and its flamboyant coloring. In 1937 he worked at Chartres, living at the château of a collector-friend, and under the influence of less urgent circumstances his painting lost some of its agitated and volcanic quality. Although some of Soutine's work showed a strong Classical influence, he is remembered today chiefly as an expressionist. He finally took refuge at Champigny-sur-Veude, where he died, Aug. 9, 1943. H. Bol.

**SOVIET UNION.** *See* RUSSIA, HISTORY OF; UNION OF SOVIET SOCIALIST REPUBLICS.

**SOW BUG,** a small terrestrial crustacean, belonging to the order Isopoda, which is usually found under logs, boards, stones, and in similar damp places. The habitat of this crustacean and the fact that many of the species roll themselves into a ball when disturbed have led to the names wood louse and pill bug. Sow bugs are found in most regions of the world; their adaptation to a terrestrial environment is so nearly complete that some forms are even encountered in desert areas where few other animals can survive. Some of the species are destructive to seedlings and young plants and are therefore considered pests in greenhouses. The young emerge from the egg in a brood pouch beneath the body of the mother and remain there until they reach a form similar to that of the adult and are able to shift for themselves. They range from less than ⅛ in. to well over an inch in length. F. A. C.

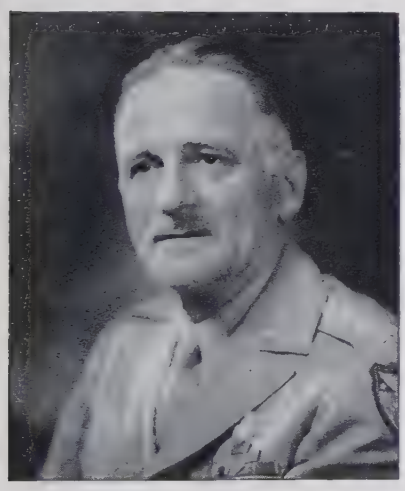
**SOWERBY, LEO** [so'ərbi] (1895- ), American composer and teacher, was born in Grand Rapids, Mich., May 1, 1895. He received the first fellowship at the American Academy in Rome in 1921 and in 1925 became professor of composition at the American Conservatory in Chicago. Two years later he was appointed director of music at St. James's Episcopal Church in that city. Sowerby is a prolific composer and his works have been widely played. His compositions include a symphony, a symphonic poem (*Prairie*), a symphony for organ alone, concertos, chamber music, songs, piano and organ pieces, and sacred choral works. He won the Pulitzer Prize for music in 1946 for his *Canticle of the Sun.* D. L. E.

**SOW THISTLE** [sau'], a genus, *Sonchus,* of coarse annual or perennial herbs of the family Compositae, native to the Old World. Four of the 45 species have become troublesome weeds in North America. These herbs are smooth, leafy-stemmed plants bearing lobed leaves which have prickly margins, and terminal clusters of yellow flower heads, borne in late summer. The achenes bear a pappus of many soft, white bristles. J. C. Wis.

**SOYBEAN,** a common name for *Glycine soja,* an erect annual of the legume family, native to China and Japan. The plant, 2 to 6 ft. in height, bears inconspicuous white or purple flowers and pendent, brownish, hairy pods. It is an important human food crop in the Orient. In Europe and the United States, the plant is grown for forage and soil improvement. The seeds yield valuable products such as oil, flour, and meal. The oil is used in the production of paints, lubricants, soaps, and in many synthetic products. The meal is utilized as stock feed and fertilizer. C. R. Eb.

**SPA** [spɑ′], the oldest and original European spa or watering place, located in a picturesque forested area surrounded by mountains, about 17 mi. southeast of Liège, in east central Belgium. The general term "spa" came into use after the city of Spa in the sixteenth century became famous for its baths and mineral springs and healthy climate. Spa was once fortified and walled, and it is believed to have been occupied in part by the Romans. Several fires, notably in 1644 and 1807, destroyed parts of the town, but it was rebuilt and its casino, bath house, promenades, museum, music halls, libraries, numerous fashionable hotels, and an artificial lake continue to attract from 14,000 to 18,000 visitors annually, chiefly from May to October. Spa reached its zenith of popularity during the eighteenth century when it was patronized by Henry III of France, Charles II of England, Queen Christina of Sweden, and Peter the Great of Russia. During World War I the famous resort was used as a hospital and convalescent center and after March 1918 served as a German headquarters. In July 1920 it was the scene of the Conference of Spa where German disarmament, coal delivery, and war crime trials were discussed by the Allies and German delegates. The only industrial items produced in Spa are lacquer wares and liqueurs, the latter being known as Elixir de Spa. Pop. 1952, 8,943. E. Ma.

**SPAATZ, CARL** [spa′ts] (1891- ), American Air Force officer, was born in Boyertown, Pa., June 28, 1891. He graduated from the United States Military Academy at West Point in 1914, entered the air corps in 1915, and in



CARL SPAATZ

INTERNATIONAL NEWS

1917, during World War I, was sent to France as a major in command of an air squadron. He first trained pilots at Issoudun and later, in 1918, flew combat missions. After the war, Spaatz held various posts in the air force, including the command of the airplane *Question Mark* during its six-day endurance flight in 1929. In 1933 he became chief of training and operations division in the Office of the Chief of Air Corps, and in 1941, a year after he visited England as a special military observer, he was appointed Chief of Air Staff, where he was second in command to Major General Henry H. Arnold. After the outbreak of World War II, he was named commander in chief of the United States Army Air Force in England in July 1942 and in February 1943 became deputy commander of the allied air force in the North African theater. In January 1944, Spaatz was placed in command of the United States Strategic Air Force in Europe and in 1945 assumed a similar post in the Pacific war against Japan. He was appointed commanding general of the United States Army Air Forces in 1946 and retired in 1948. R. T.

**SPACE AND TIME,** terms used in philosophy to describe the structure of nature. They are sometimes conceived as containers in which all natural events and processes occur, and sometimes as relations which connect such events. Space refers to the forms of externality and coexistence; time refers to those of succession and change. Because of the difficulty in conceiving a first or a last instant in time, or an end point in space, both time and space are commonly considered to be infinite in extent. They are usually judged to be homogeneous throughout—space in the sense that there are no hills or hummocks, and time in the sense that it always flows at the same rate. Both space and time are commonly said to be continuous, since they contain no breaks or holes. Opinion differs as to whether they are also continuous in the sense that they are infinitely divisible; certain philosophers, among whom was Zeno, have had great difficulty in conceiving how a finite duration could ever be formed by adding together an infinite number of instants. Space differs from time in at least two ways. Space is three-dimensional while time is one-dimensional. Furthermore, space is indifferent to direction, since the order of right and left, or of up and down, can easily be reversed by adopting a different point of reference; but time seems to have an "arrow" which is fundamental to its nature, since a time which flows backward is essentially inconceivable.

**Historical Controversies.** The two most important historical controversies over space and time are, first, whether empty space is possible, and, second, whether space and time are objective or subjective. The Greek atomists had no difficulty in conceiving unoccupied space and thought it a necessary condition of motion; but Aristotle considered empty space an impossibility. Sir Isaac Newton conceived both space and time after the pattern of absolute containers in which events might or might not occur. Immanuel Kant argued for the subjectivity of space and time, maintaining that they were *a priori* forms of perception, projected by the mind on a world which was not itself in either space or time. F. H. Bradley endeavored to show that the real world cannot be either spatial or temporal since these notions prove to be riddled with contradictions when we try to understand them. Henri Bergson claimed that we can truly grasp the nature of time only when we experience it as pure duration and abandon the scientific technique of analysis by which it is broken up into a series of durationless instants. With the beginning of the twentieth century, theories of space and time became greatly influenced by science. Physics contributed information concerning the way in which space and time are measured, geometry suggested theories of the various types of order, and psychology provided facts with regard to the nature of our perception of space and time. As a result of these discoveries there has been an increasing tendency to think that a philosophical approach to the problems of space and time involves a critical analysis and integration of the information contributed by the more special sciences. *See also* Relativity; Whitehead, Alfred North. A. C. B.

**SPACE PERCEPTION,** the process through which we are aware of the spatial relations of the outside world. The average person does not consider the problems involved, since space seems to be perceived as immediately and easily as any other characteristic of objects, as their color or weight. But we have no sense organs that respond directly to space; it is not a primary sensation like the color red, or the note

middle *C*. Hence, perception of space is very complex, depending on cues obtained from several sense organs.

### TACTUAL SPACE PERCEPTION

**Empirical or Genetic Theory.** Perhaps the simplest type of space perception is seen in the ability to localize a touch on the skin. How can we tell that a fly, for example, is on a spot on our right wrist, rather than the elbow, or the other hand? One of the first answers to the question was given by Lotze in 1852, in his theory of "local signs." He held that each touch spot not only yielded a sensation of touch, like any other touch spot, but also a specific quality, its local sign, which enabled us to tell which particular spot was involved. These local signs had meaning to us only because we had learned to recognize them, during our early life, as we rubbed the skin surface against objects and explored the skin with our fingers. Thus, the local signs became our cues for localizing movements, which would bring the finger into contact with the stimulated spot. This view was an early form of the empirical or genetic theory of space perception, which emphasized the importance of experience or learning in giving us our perception of space.

Perception may be likened to the person who moves into a new house and must learn the significance of various door-bells and buzzers by running to every door when he hears a bell ring. Lotze's theory did not go all the way, however, for he assumed a given or native concept of space itself; we merely learned to localize various objects in space. Later, theorists went further and maintained that even the concept of space is learned through experience and is based on our movements and the resulting sensation.

**Nativistic Theory.** Parallel to this theory was another, the nativistic, which held that we intuitively or instinctively know about space, and that we are able to recognize the point stimulated without any training. Perhaps the most influential exponent of this view was Hering (1861). The theory has generally been less attractive to scientists, for it seems to avoid the problem by saying "We just grow that way." There has been a great deal of experimental work devoted to an attempt to decide between the two theories, but much of it gives no clear-cut answer. It has been shown, for example, that the ability to make accurate tactual localization improves with practice, apparently favoring the empirical theory. But the proponents of the nativistic theory pointed out that the practice may merely have led to more accurate localizing movements; the person may have known exactly where he was touched, even without practice, but he may have missed his aim when he tried to find the spoon with his finger.

**Present Status of Theories.** As a result of many experiments, the weight of scientific opinion swung back and forth between the two theories. The years 1925-1930 marked a strong swing toward the genetic theory, in keeping with a similar trend to deny or minimize the importance of heredity and instincts. But soon thereafter there was an increasing knowledge of the development of the embryonic nervous system, making the nativistic theory more plausible. Observations on prematurely delivered embryos of the rat and guinea pig showed that they could bring up a paw and touch a stimulated spot, although they had had no chance to practice such tactual localization. These observations, and many others, started the pendulum back again, so that the weight of opinion had swung over to the nativistic theory by 1945.

**Existing Data.** The facts that have been gathered in support of the theories are more important than the theories themselves, even in the field of tactual space. We know, for example, that the accuracy of localization varies greatly over the body. It is greatest at the finger tips, and gradually becomes poorer as we go up the wrist and arm to the shoulder. It is extremely difficult to localize a spot on the back, as anyone finds when he tries to touch an itching spot. There is a general rule that accuracy is greatest on the most mobile parts; the lips, for example, are better than the cheeks.

Another way of getting at tactual space perception is the two-point threshold. If two compass points are touched to the skin of the wrist, they are felt as one when they are close together; but if the tips are a half inch apart, they are correctly perceived as two. The minimum distance at which they appear double is called the two-point threshold, and corresponds closely to accuracy of localization. The two-point threshold is only 1 mm. (0.04 in.) on the finger tips, but it may be fifty times as great on the back.

One must not neglect the part played by the kinesthetic (muscle) sense in tactual space perception. It is not enough to know which spot on our wrist is being stimulated; we must also know where in space our wrist is. In the absence of vision, our only cue is the kinesthetic sense.

### VISUAL SPACE PERCEPTION

Much that has been said of tactual space perception also applies to visual space perception. The sensitive part of the eye, called the retina, is a slightly curved surface that lines the back of the eyeball. The light rays reflected from outside objects stimulate this surface, giving sensations of light. But when we ask how we can tell where each spot of light comes from, we have a problem similar to that of tactual localization. Answers have been given in terms of local signs, and of the two traditional theories, empirical and nativistic. But there are additional complications in vision, for visual space perception is a three-dimensional process. It can be broken into two parts, perception of direction and perception of depth.

**Perception of Direction.** Perception of direction is similar in many ways to tactual perception. There is one difference, however, for we do not localize objects at the point of stimulation on the retina, as we do on the skin. Instead we project them along a straight line drawn from the point stimulated, through the lens, and continuing for an indefinite distance. All we can know as a result of a retinal point is the direction of an object; we cannot tell how far away it is. Even this perception requires other cues, for we must know how our eye is directed, how our head is held in relation to our trunk, and how we are standing. All this information comes to us from sense organs in eye muscles, neck and trunk muscles, and the equilibratory mechanism of the inner ear. All these clues are put together in an automatic fashion, so that we can point to an object when we see it, and say: "There it is."

This description applies to the perception of direction of a single point, as a star. But most objects stimulate many retinal points, forming a mosaic pattern. The problems of the interaction of the points which make up such a pattern become quite complicated. There is, for example, a tendency to fill in points that are missing in the image of a known object or a regular figure.

**Depth Perception.** It is not enough to know the direction of an object, for we must know how far away it is before it can be localized in space. Depth cannot be furnished directly by the retina, which is only a surface. The accommodation muscle of the eye which focuses the image gives us one depth cue. Another cue comes from the amount of convergence which is necessary to point the two eyes at

an object. The nearer the object, the greater the convergence, and the greater tension on certain muscles that move the eyes. A more powerful depth cue comes from slight differences in the object as seen by the two eyes. These may be called primary or direct cues. But we also get a great many depth cues from the change in appearance of a known object the further it gets away. The artist uses these secondary cues to give an appearance of depth to his pictures. One of the most powerful is linear perspective. The artist makes parallel lines converge as they recede into the distance. This is really a special case of the general rule that objects cast smaller retinal images as they get further away. Closely related, and based on the same geometrical principle, is the apparently slower motion of distant objects. Another extremely powerful clue is the distribution of shadows. A good portrait photographer utilizes this factor when he makes a long nose seem shorter by directing light in a special direction. In general, distant objects are hazy, because of haze in the atmosphere. Finally, one can be certain that a tree is behind a house if the house hides part of the tree.

It will be seen that all of these secondary cues to depth depend upon knowledge of the object. Hence, we can readily set up unusual conditions that deceive us, leading to illusory perception. A miniature hill, with trees and houses all built to a scale of one to ten, would look like a real hill, but ten times as far away as it actually is. But if the illusion is to work effectively, all conflicting cues must be removed. Binocular cues and the effect of head movement would be most apt to spoil the illusion; they can be eliminated by viewing the scene through a peep-hole. Artists have long recognized this fact, and often examine their paintings monocularly through a tube. This eliminates the binocular clues that make the picture appear flat, and permits the picture to appear in good depth.

**Other Illusions.** Just as the factors involved in depth perception can be clarified by illusions, so can other fields of space perception. There are a large number of geometrical illusions, such as the one in which a pair of parallel lines appear to diverge if they are cross-hatched like the familiar herringbone pattern. A vertical line looks longer than an equal horizontal line, and a bisected line looks shorter than an unbroken one. These illusions and many others must fit into any complete theory of space perception.

Perhaps the most enlightening illusions are those based on orientation to the vertical. Certain amusement parks have "crazy rooms," in which the whole room—floor, walls, and furniture—is tipped up so that the floor makes an angle of perhaps 30 degrees with the horizontal. When we enter this room there is a conflict between our visual perception of the vertical, and our postural-kinesthetic perception. At first, we are dizzy and confused, but we soon become adjusted, and accept a compromise between our two perceptions. Illusions such as this one show that space perception actually involves the co-operation of many different sense organs and muscles, integrated by the brain into an apparently simple pattern; actually a very large part of our body is involved in even the simplest example of space perception.
*See also* SENSATION. H. Sc.

**SPADEFISH,** *Chaetodipterus faber,* a deep bodied fish related to the butterfly fishes, but in the family Ephippidae. The body is much compressed laterally and is approximately circular in outline with an almost vertical forward profile. Color pattern changes from a vertically barred white and black to one that is nearly all white or all black. Spadefish range from Cape Cod to Brazil but are more common toward the south. They are most abundant in bays near rock piles and wrecks where they feed on crustaceans and comb jellies. Spadefish attain a size of 3 ft. and weigh 20 lb. but most specimens average about 1 ft. They are a fine food fish although few are taken commercially along our shores.
E. C. R.

**SPADEFOOT TOAD,** a toad having tubercles on the inner sides of its hind feet with which it digs in sandy soil. *Pelobates* is the European genus, and *Scaphiopus,* the American. Strictly nocturnal, these toads breed in water and are distinct from other toads in that their eyes have vertical instead of horizontal pupils; also, their skins are only slightly tubercular, rather than warty. When seized, they often emit a shrill cry. Some species secrete an offensive substance from the skin. A. Sv.

**SPAIN,** a country in southwestern Europe, occupying about 85 per cent of the Iberian Peninsula. Located between 36° and 43° 45′ N. lat., and 3° 20′ E. long. and 9° 30′ W. long., Spain is bounded on the north by the Bay of Biscay and France, from which it is separated by the Pyrenees Mountains, on the east and south by the Mediterranean Sea and the Atlantic Ocean, and on the west by Portugal and the Atlantic. The Strait of Gibraltar separates it from the northwestern tip of North Africa. Including the Balearic Islands (1,936 sq. mi.) and Canary Islands (2,807 sq. mi.), which in 1927 were incorporated as Spanish provinces, the total area of Spain is 194,945 sq. mi.

## GEOGRAPHICAL FEATURES

**Topography.** The extreme distance from north to south is 540 mi. and from east to west 620 mi. The coast line is over 1,300 mi. long with approximately 700 mi. facing the Mediterranean and 600 mi. the Atlantic and Bay of Biscay. Along the northern coast from the French border west to Cape Ortegal the mountains parallel the sea and there are few indentations large enough to serve as harbors, but along the Atlantic south of Cape Ortegal the mountain spurs reach the sea in a submerged ria type of coast with sheer cliffs, deep harbors, and numerous offshore islands. In this area are the fishing ports of La Coruña and Vigo. In the southwest from the Portuguese border to the Strait of Gibraltar the coast is low and marshy, with Cádiz its only good harbor. From Gibraltar east to Cape Palos the Sierra Nevada descends abruptly to the Mediterranean and there is little or no coastal plain, but north of Cape Palos is a series of narrow coastal plains broken occasionally by mountain spurs. Cartagena, Valencia, and Barcelona are the three major harbors on the Mediterranean.

Physiographically, Spain consists of an ancient crystalline block with alpine mountain ranges of Tertiary period to the northeast and southeast. Between the central block, or Meseta, and the northern range is a tectonic basin through which flows the Ebro River, while between the Meseta and southern mountains is another structural basin occupied by the Guadalquivir River. The Meseta itself is a horst of flat-lying Pre-Cambrian schists and gneisses with granitic intrusions, particularly in the north, and with Paleozoic outcroppings throughout the region. Originally part of the late Paleozoic Hercynian mountain system, this block was folded, faulted, worn down to a peneplane, and partly covered by Tertiary strata, especially in the basins of Old and New Castile. During late Tertiary times the block was again uplifted to an average elevation of about 2,000 ft. with a decided tilt from northeast to southwest. This accounts for the fact that several large rivers originate in the eastern

part of the Meseta and flow westward across it to the Atlantic, instead of turning eastward to the Mediterranean. The Meseta is bounded on all sides by fault scarps and occupies about two thirds of the area of Spain. A number of smaller horsts on the Meseta itself cause local mountain ranges, such as the Sierra de Guadarrama, over 7,000 ft. high, between the basins of Old and New Castile, and the Montes de Toledo to the southwest. In the northeast the Iberian Mountains bordering the Aragon Lowland represent the upturned northern edge of the block and rise locally to about 7,000 ft. In the south the Sierra Morena borders the Andalusian Lowland and is formed by the upturned southern edge of the Meseta. The Cantabrian Mountains in the northwest lie generally in an east-west direction and have been faulted and folded as well as deeply dissected. Elevations reach over 8,000 ft. Young alluvial deposits cover much of Old and New Castile and make these areas between the mountains extremely flat. The only elevations are the long mesas lying as flat terraces above the lowlands. The basin of Old Castile is drained by the eastward flowing Duero, while that of New Castile is drained by the Tajo (Tagus), which also empties into the Atlantic.

*The Alcantara Bridge, which spans the Tajo River at Toledo, includes masonry of every period of the city's history. Until the thirteenth century it was the only means of approach. The Alcazar, destroyed by fire in 1887 and rebuilt in the 1920's, also played an important part in Toledo's history.*

PHILIP GENDREAU

Northeast of the Meseta, and separated from it by a fault scarp, is the Aragon Lowland, a wedge-shaped depression floored by Tertiary sedimentaries. To the north are the Pyrenees Mountains, to the west and south the uplands of the Meseta, and to the east the coastal Catalan Mountains. The Ebro River rises in the northwest and flows east and south through the depression, eventually cutting its way through the Catalan Mountains to the Mediterranean. Although the river is deeply entrenched, extensive government irrigation projects have been undertaken to make agriculture possible in the arid valley.

The Pyrenees, bordering the north of the Aragon Lowland, extend for about 240 mi. from east to west between the Mediterranean and the Bay of Biscay and form an effective, almost unbroken barrier between the Iberian Peninsula and the rest of the European continent. Folded against the crystalline Meseta during Tertiary times, the mountains rise in several sections to over 10,000 ft., the highest point being Pico de Aneto (11,169 ft.). Extending southwestward from the eastern end of the Pyrenees are the low Catalan Mountains, which were also formed during the Tertiary period. With elevations of from 3,000 to 4,000 ft., they parallel the Mediterranean coast for about 250 mi. and effectively shut off the Aragon Lowland from the sea. A narrow but fertile coastal plain follows the Mediterranean coast north of Cape Palos.

Southeast of the Meseta is the Betic or Andalusian Lowland, a long syncline running northeast from the Gulf of Cádiz. Like the Aragon Lowland the depression was occupied during Tertiary times by an arm of the sea, and the underlying rock is predominantly Tertiary. Much of the floor today, however, is covered by recent alluvial deposits, making the area extremely fertile. The Guadalquivir River flows through the Andalusian depression to empty into the Gulf of Cádiz. Near the delta is an extensive area of marshes known as Las Marismas.

In southeastern Spain is the Penebetic mountain chain, of which the lofty Sierra Nevada is the most famous range. This chain, like the Pyrenees, was folded and uplifted during the Tertiary period. It extends from Gibraltar northeast to Cape Nao, with many of the hills averaging 4,000 to 5,000 ft. in elevation. The Sierra Nevada, however, rises to over 10,000 ft., culminating in Mount Mulhacén (11,420 ft.), the highest peak on the Iberian Peninsula.

**Rivers.** The major rivers of Spain are the Tajo (566 mi. long), Guadiana (515), Duero (485), and Ebro (480). Of these, the first three flow westward to the Atlantic, as does the Guadalquivir (374 mi.) in the Andalusian Lowland and the shorter Miño (171 mi.) in the northwest, while the Ebro and a number of short mountain streams flow eastward to the Mediterranean. Of all the rivers, only the Guadalquivir is navigable for any distance in Spain itself. Seville, 60 mi. upstream, is a thriving seaport. In the case of the other streams navigation is prevented both by lack of sufficient water during much of the year and by numerous waterfalls and rapids. Most of the rivers are entrenched in canyons, making utilization of their water for irrigation a difficult and costly undertaking. The Ebro alone has been developed extensively for this purpose. On the other hand, the use of these rivers for hydroelectric power is hindered by the small amount of water available. Only in the northwest and along the slopes of the Pyrenees is there ample water supply throughout the year, and here considerable hydroelectric development has taken place.

**Minerals.** Spain is richly endowed with mineral wealth. Iron ore is mined in the Cantabrian Mountains near Santander, as well as in the Penebetic Mountains to the south. Coal deposits are found in northern Spain near Oviedo. From Almadén in the Sierra Morena comes approximately one-third of the world's mercury, while the famous Río Tinto copper mines of the southern Sierra Morena have been worked since the end of the thirteenth century. The Linares lead mines, northeast of Córdoba on the southern slopes of the Sierra Morena, have been in production for over 2,000 years. Zinc, silver, manganese, cobalt, potash, and wolfram, although in lesser quantities, are also important to Spain's economy.

**Climate.** The climate of Spain may be subdivided into three types: the temperate marine climate of the northwest and north with moderate temperatures and ample year-round precipitation, the Mediterranean climate of the south and east coasts with mild moist winters and hot dry summers, and the arid continental climate of the interior with its cold winters and warm dry summers. Throughout most of Spain the great determinant factor for agriculture is the water supply. The average annual precipitation varies from over 60 in. in the northwest and on the western slopes of the Pyrenees to less than 10 in. in the Aragon Lowland and La Mancha district of Old Castile. Over half of Spain has an average annual rainfall of less than 20 in. and only about 20 per cent enjoys more than 40 in. per year. Irrigation is necessary along much of the eastern and southeastern coast and in the Aragon Lowland, but the Andalusian depression in the south faces westward to the moisture-bearing winds of the Atlantic so that rainfall here is heavier. Seville has an average annual precipitation of just over 20 in. Over large areas of the Meseta rainfall is inadequate for agriculture, although in the northern part of New Castile enough is received from the Atlantic to permit extensive wheat growing. Madrid has an average annual precipitation of 16 in., but this figure increases appreciably on the higher slopes of the mountains throughout the Meseta.

Temperatures are in general moderate except for areas on the Meseta. In the northwest mean January readings average about 45° F. and August 70° F. At Murcia on the east coast the figures are 50° and 79° respectively. The massive Sierra Nevada protects the southern Mediterranean coast from northern winds, and the climate here is actually of an African type with low humidities and extreme summer heat. It is a region of date palms, bananas, and sugar cane. Winters are cold on the Meseta; severe frosts and even heavy snowstorms are not uncommon. Summers are hot and dusty with the mean temperatures of July and August averaging about 80° F. over much of the area. At Madrid the January mean temperature is 40° F. and in July 77° F. The Andalusian Lowland is, in summer, the hottest part of the country. At Seville the mean August reading is 85° F., and the thermometer may rise in an average year to over 115° F. Winters are mild, with a January mean at Seville of 52° F.

**Soils.** Several types of soil are found in Spain. Covering most of the Meseta are the chestnut-brown soils of semiarid regions. In the south and along the northeastern coast are red Mediterranean soils, while in the southeast are found gray desert soils which are often saline in character. Gray-brown forest soils occur in the deciduous forest areas of northern Spain, and in the coniferous forest belt of the Cantabrian Mountains leached podsol soils are developed.

**Flora and Fauna.** The variety of climatic conditions in Spain, ranging from the more moist and humid northern area to the arid and semi-African regions of the south, has produced a corresponding profusion of different forms of vegetation. Those in the north of the peninsula are representative of the Central European groups, while the various species in the south often reveal African affinities.

At one time Spain was well forested, as indicated by various degenerate forest areas in Murcia, La Mancha, and Granada. At present only 5 per cent of the country's total forest area can be called true forest, and of this one third is pine wood. Deciduous trees are more common in the north, with such Central European species represented as oak, beech, ash, birch, and chestnut. The evergreens are found principally in the arid regions and consist of the Spanish pine, pinaster, and Corsican pine. The oaks are represented by two species: the evergreen oak and the holm oak. In the extremely dry sections of the south, semidesert conditions prevail and the types of vegetation resemble the scrub types found in similar areas of northern Africa. Along the east coast, where there is a much heavier rainfall, a typical Mediterranean floration exists; it is reasonably heavy and contains some semitropical plants and trees, such as citrus fruits.

The fauna of Spain shows the same mixture of European and African types. Among the European forms existing in the peninsula are the Spanish lynx, the Andalusian wildcat, the Spanish wolf, the Spanish fox, and various species of deer, hares, squirrels, and moles. Of special interest among the African types is the Barbary ape of the Rock of Gibraltar. This is the only ape native to the European continent, and it probably came from Africa in comparatively recent times. A species of eagle, the Spanish Imperial, is found both in Spain and North Africa, and the azure-winged magpie of the peninsula has also been discovered in eastern Asia. The genet, the ichneumon, and a certain species of chameleon can be found on both sides of the Strait of Gibraltar. L. M. A.

## ETHNOLOGY AND POPULATION

**Racial Origins.** No simple account can be given of the inhabitants of Spain. Several different racial types appear to have been present in the peninsula since prehistoric times, and a considerable mixing has inevitably taken place. Ancient authorities list the various names of early peoples coming into Spain, but little is known of origins or factual realities behind the names. The best contemporary opinion is that the earliest inhabitants were round-headed, olive-skinned Ligurians about whom practically nothing is known.

At a very early period there was an invasion of long-headed Iberians from North Africa who settled in the east and south. In about 900 B.C., and again in about 600 B.C., there were Celtic invasions from the north; these resulted in a definite Iron Age civilization in the northeast and northwest which had contacts with similar civilizations north of the Pyrenees. On the other hand, the Iberian peoples probably maintained contacts with Africa. It is doubtful if the Greek or Carthaginian settlements had any far-reaching effects on the ethnology of Spain; nor did the Romans contribute any particular racial type to the peninsula. The Arab and Berber invasions from A.D. 711 to 1200 probably resulted in a darkening of skin color in Andalucía which is still discernible. Generally speaking, the inhabitants of modern Spain fall roughly into several racial groups, of which the most clearly marked are a long-headed Iberian type and a round-headed Celtic type.

**Language.** The Spanish language is derived from spoken rather than written Latin, and exists in various dialects such as Andalusian, Galician, and Castilian; this last is considered the purest form of the language. Special mention, however, should be made of Catalan, which is a derivative of medieval Provençal; and Basque, which is unlike any other language found in modern Europe. There is little trace of the ancient Iberian tongues in modern Spanish, and only a comparatively few words are of Arabic or Gothic origin; the Latin influence is predominant. The language itself is musical and flexible; it is rich in idioms, and lends itself to florid and picturesque modes of expression.

**Religion.** The great majority of Spaniards belong to the Roman Catholic Church, although there are small minorities of Protestants and Jews. Catholicism was a state church until the establishment of the Second Republic in 1931, when it was separated from the government. However, following the successful revolt led by General Francisco Franco, the new government re-established formal relations with Rome by a concordat signed June 7, 1942, giving the government the right to nominate to episcopal vacancies.

**Population.** Early estimates of the population of Spain are entirely unreliable, but it is usually assumed that under the Romans and Mohammedans it was considerably larger than in modern Spain. The first reliable census gave a figure of 10,268,150 in 1787; in 1930 the population had reached 23,563,867, and the estimate for 1952 raised it to 28,600,000. The largest provinces are Barcelona, Madrid, and Valencia, the first with over 2,000,000 inhabitants and the last two with over 1,000,000. According to the same estimate, the largest cities are: Madrid, the capital, 1,440,041; Barcelona, 1,268,973; Valencia, 525,630; Seville, 382,564; Zaragoza, 266,684; Málaga, 292,595; Murcia, 215,234; and Bilbao, 230,507. Spain is primarily an agricultural country, and the great majority of its inhabitants live in rural rather than urban areas. It is estimated that fully 70 per cent of the people work on the soil, while the remainder are found in the crafts, professions, and laboring groups.

## GOVERNMENT AND POLITICS

**Central Government.** The regime in Spain since 1939 (the end of the civil war) is officially a monarchy. The chief of state, popularly known as *el caudillo* (leader), is Generalissimo Francisco Franco. He unites in his person full executive, legislative, judicial, and military authority. Although a legislative body known as the Cortes was established on July 17, 1942, it is seldom summoned and meets only to approve Franco's decrees if he submits them for approval. It is not a popular body since two thirds of the members are appointed by the *caudillo* and one third is elected by labor-employer groups known as national syndicates. To assist the chief of state in his executive functions, there is a cabinet of twelve ministers who supervise such departments as foreign affairs, finance, war, and so forth. This cabinet is not responsible to the legislature, but only to the *caudillo.*

The judicial powers of the government are exercised through the Ministry of Justice and the system of courts. However, since the end of the civil war, political crimes have made up much of the business of the judiciary, and special laws and courts have been set up to meet this situation. The Law of Political Responsibilities, enacted on Feb. 9, 1939, defines seventeen categories of crimes against the state, ranging from direct action against the government to the vague charge of "acts contributing to the anarchy prevailing before the Nationalist Movement." This law is enforced by the regular courts, by courts martial (since Spain is technically still under martial law), and a Special Tribunal for the Repression of Masonry and Communism. To obtain evidence, the government relies on the regular police, *Dirección General de Seguridad,* the state secret police, *Guardia Civil,* and the Falange secret police.

**Civil Rights.** As in most totalitarian states, civil rights are rigidly restricted, though they were theoretically granted in 1945 by the law *Fuero de los Españoles.* Freedom of press and speech do not exist; an effective censorship supervises stage and screen production, and all publications, indicating what the government will permit the public to read, see, or hear. Discussion of certain topics, such as governmental reform, or a monarchist restoration, are strictly forbidden. Academic freedom in the universities is likewise restricted; the subjects taught are supervised, as are the professors, while courses in political indoctrination are required for all students.

**Political Situation.** The only political party in Spain is *La Falange Española,* and its chief is Generalissimo Franco. Under him, the party is governed by a national council, a political committee, and various regional representatives. It has its own police, worker-employer syndicates, and youth organizations. There is also a philanthropic organization known as *El Auxilio Social.*

**Finance.** Since the civil war of 1936-1939, government finances have been seriously disturbed. Deficit financing, war, and reconstruction costs have kept taxes high without removing inflationary tendencies. The increase in government spending is reflected in the rise of the budget from 7,200,000,000 pesetas in 1940 to 22,745,000,000 pesetas for ordinary and extraordinary expenditures in 1952. The peseta, officially stabilized at 10.95 to the United States dollar in 1945, was worth .0918 cents in United States currency on Jan. 3, 1950.

**Government Enterprises.** The government engages in a program of economic and social legislation. Plans are being carried out for rural electrification, irrigation, and reforestation. The railroads were nationalized in 1941, and tin, copper, aluminum, zinc, manganese, nickel, chromium, and tungsten mines were brought under government aid and control. At the same time, social legislation was drawn up to provide marriage loans, family relief, and the like.

**Armed Forces.** The Spanish army consists of about 400,000 men, making it one of the largest in western Europe. It played a decisive role in the Nationalist victory, and has been greatly favored by Franco, in 1950 receiving a lion's share of the appropriation (31.8 per cent) for national defense. Although the Falange is supposed to be a rival of the army, it is not a serious threat. The army has amicable

UNDERWOOD - STRATTON

*THE ALHAMBRA, THIRTEENTH-CENTURY MOORISH PALACE, OVERLOOKING THE CITY OF GRANADA, SPAIN*

relations with the Church, and at the end of 1950 observers saw nothing to endanger its commanding position in the regime. The navy consisted in 1951 of 6 outdated cruisers, 22 destroyers, 5 submarines, and numerous smaller craft. The air force, an independent service, is divided into an air branch of planes and parachutists and an air infantry for operation of ground installations.

**Colonial Possessions.** The Spanish colonial empire consisted in 1950 of territory in Morocco, the western Sahara, and Spanish Guinea. With the exception of Morocco, which was considered a protectorate, these areas were governed directly from Madrid. Colonial government in the Franco regime was first supervised by the vice-president, then transferred to the Ministry of Foreign Affairs; finally, on Jan. 23, 1942, it was turned over to a directorate-general, directly under Franco.

## ECONOMIC RESOURCES AND ACTIVITIES

**Agriculture.** The backwardness of agriculture is one of Spain's major problems. The situation has been summed up by one Spanish authority in the phrase: "men without land, and land without men." In such northwestern areas as Galicia, León, and Asturias, the individual holdings are very small, the average figure for Galicia being 2.5 acres per family. As one proceeds southward, small holdings disappear and *latifundismo* (the ownership of large landed estates) becomes much more common. Generally, although 70 per cent of the population derives its living from the soil, only about 10 per cent control it. The areas of the great estates under cultivation are worked by a landless proletariat, who receive very low wages and live under the most adverse conditions. Attempts made by the Second Republic to break up large holdings were, for the most part, unsuccessful; and, since the Franco regime came into power through the support of the landowning classes, its approach to the agrarian question has been highly conservative, being confined to rural electrification, irrigation, and reforestation. One of the worst aspects of Spanish agriculture is the large amount of uncultivated land, principally in the center and south. An estimate made just before World War I placed the amount of uncultivated land at more than 13,000,000 acres. While some of this land is bad, most of it could yield an average crop if carefully worked, in the opinion of observers. However, the great landowners have not wished to go to the expense of bringing additional land under cultivation and the land remains uncultivated, in spite of the fact that the national food supply is insufficient.

The principal crops are potatoes, grapes, and wheat. In 1950 the production figures were: 2,800,000 tons of potatoes, 2,411,000 tons of grapes, and 3,382,000 tons of wheat. Because of bad weather, lack of fertilizer, and the generally obsolete techniques employed, recent estimates of agricultural production are still considerably below prewar figures. Because of these shortages, food prices were still rising in 1950. The raising of livestock is an important phase of Spanish agriculture. The Andalusian horse and bull, the

merino sheep, the Pyrenean mule, and the Spanish goat have long been in great demand and are widely raised. In 1918, the total livestock of the country was estimated at 31,000,000 head; in 1948 the estimated figures gave 25,921,303 sheep, 4,221,759 goats, and 2,688,111 swine.

**Mining.** Coal and iron are the bases for important mining industries in Spain. Coal is found in many provinces, of which the most important are Asturias, León, Burgos, Gerona, Ciudad Real, and Seville. In 1950 Spain produced about 11,044,000 tons of coal and nearly 2,500,000 tons of iron ore. The iron and coal industries have profited considerably from the investments of foreign capital. However, the development of new iron and coal resources has been handicapped by poor transportation. Besides these two industries, the mining and working of copper, lead, zinc, mercury, tin, tungsten, silver and gold, bismuth, antimony and sulphur are important. Almost every known mineral can be found in Spain, although some of them exist only in minute deposits.

**Industry.** Generally, because of a very late start, lack of national capital, and the weak state of the Spanish economy, the industrial development of the nation is still greatly below current needs. Iron and steel production are located principally in three areas: Vizcaya, centering in the city of Bilbao; Valencia, centering at Sagunto; and León, concentrated in the city of Ponferrada. Other important industries in modern Spain use large quantities of chemicals in the making of fertilizers, pharmaceutical products, and perfumes, and in wood distillation. Some industries are favored because of the availability of excellent Spanish olive oil. The textile industry is an ancient one, probably dating from Moorish times, and currently is one of the most important in Spain. It specializes in the manufacture of cotton, silk, and wool; its chief center is Barcelona, largely because of the double advantages afforded by a great port and the hydroelectric developments in the Pyrenean valleys.

**Fishing.** Because of Spain's long coast line, sea fishing has become an important occupation. In 1948 there were 1,201 canning factories and the total catch in 1951 approximated 495,000 tons, mostly sardines, tunny fish, and cod.

**Commerce.** Spain's foreign trade was stimulated by World War II. In an effort to keep wolfram, mercury, and other strategic materials out of enemy hands, the Allies bought heavily in the Spanish market. Agreements with Argentina enabled Spain to exchange ores and manufactures for Argentine grain and tobacco. In 1942, the trade balance was favorable for the first time since 1930. However, at the end of the war Allied buying ceased, the supply of foreign exchange needed for purchases abroad was depleted, and some overseas markets were lost because of hostility to the Franco regime, under which Spain was excluded from the United Nations. Although trade agreements had been concluded with Argentina, the Netherlands, and Italy, the trade balance in 1948 was adverse; imports totaled 470,673,000 dollars and exports only 364,056,000. The note issue of the Bank of Spain was raised on Dec. 18, 1950, from 28,000,000,000 to 35,000,000,000 pesetas, and this introduced an inflationary trend which made the commercial outlook even more grave than before.

**Transportation and Communications.** Even before the civil war of 1936-1939, the Spanish railroad system, handicapped by rugged terrain and a weak national economy, was inadequate. After the civil war the new government estimated the cost of repair at $30,000,000, but, even had this sum been immediately available, the outbreak of World War II stopped supplies from abroad and Spanish industry lacked the capacity to furnish the necessary material. Some restoration was made. In 1941 all standard-gauge lines (7,950 mi.) were nationalized. Total rail mileage was 10,920 in 1947. Although there are 80,141 mi. of highways and roads, the highway system is inadequate to meet modern demands. Regularly scheduled air lines operate between the major Spanish cities, as well as between Spain and other countries. Telephone, telegraph, radio, and cable services are all either owned or controlled by the government.

**Labor Restrictions.** The growth of labor unions and confederations of unions was ended by the Nationalist victory in the civil war. As in most totalitarian countries, unions were replaced by vertical syndicates, including both employers and employees, and strictly controlled from the top by *Falange Española.* Strikes and any sort of independent labor activity were forbidden.

## SOCIAL AND CULTURAL ACTIVITIES

**Standard of Living.** The general standard of living in Spain, already low for centuries, has become even more precarious since the end of the civil war of 1936-1939. The backward state of agriculture, the relatively weak industrial system, the inadequate transportation system, and the damage and shortages caused by the civil war have contributed to this situation. Many cities, badly damaged by the fighting during the civil war, were still unrepaired six years after the end of hostilities, and recovery since then has been slow. Although various laws provide social benefits and pensions, their coverage and payments have been inadequate to meet existing economic conditions. Generally, the vast majority of Spaniards suffer from great deficiencies in food, clothing, housing, and the necessary medical supplies and care. While living conditions have been bad in the cities, they have been worse in the rural areas, where famine conditions have barely been averted on occasions.

**Education.** Spanish education has long been controlled by the Catholic clergy. The Second Republic had tried to establish state-controlled schools, but these efforts ceased with the Nationalist victory in 1939. On July 17, 1945, the new regime passed the Law of Primary Education, which reestablished the church in education. It was given full authority for teaching faith and morals, and the right to require a course of religious indoctrination for all teachers before permitting them to teach. Higher education is strictly supervised. Although primary education is free and compulsory, Spain still has one of the highest illiteracy rates in western Europe. However, the nation has not failed to produce leaders in modern European culture. Spain's great cultural traditions have been represented at home and abroad during the twentieth century by such leaders as Ortega y Gasset, Santayana, and Unamuno in philosophy; Iturbi, de Falla, and Casals in music; Ibañez and Lorca, in literature; Altamira and Madariaga in history; and Picasso in art.

## HISTORY

**Ancient Times.** Very little is known about the earliest inhabitants of Spain. Ancient authorities give lists of tribes and peoples, but practically nothing is known beyond the names. About all that can be said is that Spain was first entered by the Cromagnon Man, and that various types of Stone Age culture—some of it of a fairly high order, to judge by the Altamira cave paintings—gradually developed. Then followed the Copper, Bronze, and Iron ages, and the period of the Celtic invasions from the north. The scanty records of these early times suggest that a relatively advanced culture existed in the Andalusian plain, while the areas to the center and north were more backward.

The earliest commercial contacts were with the Phoenicians and Greeks. The former may have established a colony at Cádiz as early as the eleventh century B.C. Certainly they later planted commercial posts around most of the Spanish coast and may have extended their influence inland. In the sixth century B.C., the Phoenicians of Ionia, carrying Greek culture into the western Mediterranean, finally reached the Spanish coast, where they founded the towns of Rhodae (Rosas), Emporium (Ampurias), Hemerosopium, and Maenaca (near Málaga). The Greeks are supposed to have introduced viticulture and olive growing into Spain.

After 535 B.C., Greek influence in the western Mediterranean waned and was replaced by the rising power of Carthage. This city acquired control of the eastern Spanish coast for the purpose of exploiting the silver mines and for commerce. The Carthaginians established military control over certain areas, but did not attempt a conquest of the interior. Probably they interfered very little with the local affairs of the Phoenicians and Greeks. Carthage founded both Barcelona and Cartagena, the latter being the principal military and commercial center until the advent of the Romans.

In the third century B.C., Carthaginian imperialism collided with Roman ambitions and the Punic wars resulted. The Second Punic War, 219-202 B.C., began with a dispute between the two powers over the Spanish city of Saguntum (Sagunto), and ended with the substitution of Roman for Carthaginian power in Spain. The Roman domination which was thus inaugurated was to last six hundred years, and was to be a determining factor of the greatest importance in Spanish history. By 132 B.C. the wars of conquest were ended, and the assimilation of Spain into the empire began. Administratively, the country was divided into several provinces, but the most important civilizing force was the Roman town populated with Roman colonists, including slaves, businessmen, and war veterans. First the cities were Romanized and then the rural areas. Soon Latin replaced the aboriginal tongues, and by the second century A.D., Spain was an integral part of the empire and one of its economic mainstays. It also contributed great men; Lucan, Seneca, Trajan, and Hadrian were Spanish provincials, and Marcus Aurelius also seems to have been of Spanish descent.

Christianity was introduced into Spain in the second century, and by the third century was beginning to organize itself on the basis of the Roman provincial system. Church councils held in A.D. 306, 380, and 400 set up the administrative system of the Spanish Church. During the last years of the empire, Spain suffered the usual complaints: economic decay, heavy taxation, decline in population, and inefficient rule. However, the peninsula was not successfully invaded until A.D. 409, when the Vandals appeared south of the Pyrenees; the Suevi and the Alans followed, and all three tribes occupied considerable areas. However, they were not destined to be permanent settlers, and by 429 most of them had been driven out by the Visigoths, a vigorous Germanic people who had come from the lower Danube River region under the leadership of Alaric, and had invaded Italy and southern France.

**Visigothic Spain.** The new rulers of Spain had entered the country somewhat ambiguously as allies of the Roman emperor. But, in 456, the Visigothic king, Theodoric II, ended this fiction and ruled as an independent sovereign. The expansion of Visigothic control continued, and Euric, who ruled from 466 to 484, had authority over most of Spain as well as France to the Loire River; he was thus the most important ruler of western Europe. Spain was still regarded as a dependency rather than as the center of Visigothic power, and Toulouse, in southern France, continued to be the capital until the sixth century, when a decline in the political power of the kingdom began. The energetic policies of the Frankish king, Clovis, reduced Visigothic France to a small strip around Narbonne, and by the middle of the century the capital was transferred to Toledo in Spain. At the same time the resurgence of Byzantine power under the emperor Justinian resulted in the re-establishment of certain imperial provinces in southeastern Spain. In this critical situation, the succession of the able Leovigild, who ruled the Visigothic kingdom from about 572 to 586, was opportune. He succeeded in maintaining the northern frontier against the Franks, in greatly reducing the Byzantine coastal provinces, and in conquering a few small areas that had never submitted to Visigothic control.

*EURIC, KING OF THE VISIGOTHS*

FROM AN ENGRAVING BY J. CHAPMAN

CULVER SERVICE

Leovigild is generally considered the most powerful of the Visigothic kings. Following his death, a gradual decline set in, due, in part, to certain difficulties inherent in the Visigothic state. The Visigoths were far less numerous than the people they had conquered, and it is doubtful if there was much fusion between Goth and Hispano-Roman. Both peoples used separate law codes and courts, and, in addition, there were differences of religious forms and ceremonies. Although King Recared (586-601) and his court were finally converted to the Spanish form of Catholicism, this came too late to assist in any reconciliation between the groups. Probably the bulk of the population felt little affection for an alien rule. Another fault of the regime was the weakness of the crown; the great nobles could virtually defy the king at their pleasure and were able to prevent the establishment of a hereditary crown. This situation also prevented the development of any effective administration. As economic conditions deteriorated, the small landowners were virtually swept out of existence, and gradually the population fell into two classes: the great nobles with their dependents, and the serfs. Trade and commerce almost ceased to exist. As conditions grew worse, the kings bid for the support of the clergy against the nobility and made great concessions to the power of the church. The Visigothic clergy were generally bigoted and ignorant; their persecutions of the Jews, which were frequent in the seventh century, were probably a factor in the easy Mohammedan triumph which soon followed.

Visigothic culture made few permanent contributions to Spain. It left scarcely any trace on language, art, or architecture. It did develop one of the most important legal compilations of the age, the celebrated *Lex Visigothorum*,

CULVER SERVICE

*BATTLE OF THE SPANIARDS WITH THE MOORS*

FROM A WOOD ENGRAVING

which, under its later name of *Fuero juzgo,* was to have a profound influence on Spanish jurisprudence. Generally, however, in comparison with the preceding Roman period, the Visigothic era can only be described as a period of general cultural decline. Schools had almost entirely disappeared, cities were in decay, and the ancient classical learning was rapidly being replaced by the grossest superstition. The leading scholar of the age, St. Isidore of Seville (c.560-636), revealed a faulty knowledge of Latin and little comprehension of Classical thought.

**Mohammedan Spain.** The last years of Visigothic rule were marked by internal disintegration and chaos. In 710, after a struggle for the throne between Achila, the legitimate heir, and Roderick, the candidate of the nobility, the latter was successful and was crowned. Partisans of the unsuccessful claimant may have called in the Arabs, who, by this time, had reached the Strait of Gibraltar.

The rise of this remarkable people during the seventh century forms one of the outstanding chapters of European history. Following the death of Mohammed in 632, Persia, Syria, Palestine, and Egypt were soon overrun. During the middle of the century, the Berbers, a fierce and warlike people of the North African littoral, were being repeatedly attacked by Arab armies moving westward; by 695 they were conquered, and later became the spearhead of the Mohammedan assault on western Europe. A Berber army under Tariq crossed the strait named for him, and in 711 defeated Roderick in the Battle of Río Barbate. What first may have been intended as a raid, soon turned into conquest. Tariq pressed forward to the capture of Toledo, Roderick disappeared from history, and the Visigothic monarchy collapsed. The advance forces of the victors soon crossed the Pyrenees and descended on the fertile fields of southern France; meanwhile, behind them, Spain was being organized as an emirate under the Mohammedan governor of North Africa. Although the conquest of the Iberian peninsula was complete by 718, except for small Christian remnants in the Pyrenees and Cantabrians, the consolidation of the occupied territory continued throughout the eighth century.

The relation between Mohammedan and Christian was a serious problem. The lands of the Visigothic crown and church were confiscated by the Berbers and Arabs, but many private individuals retained their holdings on payment of a tax. Similarly, while conversion was encouraged, those who wished to remain in the Christian faith were allowed to do so by payment of a fee. Conditions among the Spanish Christians varied widely. Some of the Visigothic nobility made their submission, became Mohammedans, and henceforth were known as *renegados* by the Christians; they even adopted Arabic names. However, it is equally clear that the bulk of the Christian population was never won over to the Arab-Berber regime, and frequent and sometimes bloody revolts in the large cities testified to the failure of assimilation or conciliation.

Internal feuds among the conquerors produced other serious difficulties. Relations between the Berbers and Arabs were embittered by numerous conflicts, and in 740 a Berber revolt in North Africa spread to Spain, where it was finally put down after bloody fighting by an army of Syrian Arabs brought in for the purpose. Fifteen years later, following a dynastic struggle in Syria which resulted in the extinction of the ruling Ommiad family, a young Ommiad named Abd-er-Rahman, who had escaped the slaughter of his relatives, came to Spain and set himself up as emir. With this event, the political situation tended toward stabilization. Succeeding emirs were able to defend the state against pressure from the Franks, except in the region of Barcelona, which became the Spanish March of the Carolingian empire. Revolts still continued among Christians and Berbers until they were subdued during the reign of Abd-er-Rahman III (912-961), one of the outstanding figures of his time. Shortly after his accession, he changed his title from emir to the more splendid one of caliph, thus indicating his increased power and his complete independence of the rest of the Mohammedan empire.

The period of the caliphate, 929-1031, marked the greatest splendor of Mohammedan Spain. The central government was strong, and its supremacy was not only acknowledged by the subject population but by the tiny Christian states which had survived the debacle of 711. The rich agricultural program introduced by the Mohammedans, plus a foreign trade that reached as far east as India and Ceylon, led to development of a civilization of wealth and luxury. Culturally, it was a fusion of Syrian, Persian, and Byzantine elements, unified by the Arabic language and the Mohammedan faith. The total population of Spain may have reached 30,000,000, with cities as large as Seville with 500,000, Granada with 450,000, and Toledo with 200,000. Córdoba, the capital of the caliphate, may have had over 1,000,000 inhabitants, and undoubtedly was one of the most splendid cities of Europe. Contemporaries were dazzled by its beautiful suburbs filled with gardens and palaces, its famous shops, streets, public baths, and magnificent buildings.

During the reign of the learned Hakam II (961-976) most of the wisdom and learning of the Near East were accumulated in his great library. His agents had been dispatched to Baghdad, Cairo, Damascus, Alexandria, and Constantinople for rare and valuable works. Many publications on Greek science and philosophy and Hindu mathematics were trans-

lated into Arabic and thus preserved for future recovery by western Europe. In the field of medicine, optics, and mathematics, the Spanish Mohammedans made notable contributions. In architecture, they were especially famous for their adaptation of Byzantine forms, such as the dome, and for their rich decoration (arabesques) of flat surfaces. Among the especially notable Spanish scholars were Averroës of Córdoba (1126-1198), whose commentaries on Aristotle became, when translated into Latin, the standard authority until the Renaissance; and Maimonides (1135-1204), who was the greatest Jewish scholar of his time.

While its culture and material prosperity continued to flourish for several centuries, the political supremacy of Mohammedan Spain did not long survive the caliphate. With the death of al-Mansur in 1002, a period of decline began. Civil war broke out, and in 1031, when the last of the Ommiads was deposed, the caliphate came to an end. It was succeeded by what is sometimes called the *taifa* period (from *taifa,* the Arabic word for tribe or people), when Mohammedan Spain was broken up into several small Arab states or *taifas.* At one time there were as many as twenty-three, although the *taifas* at Seville, Córdoba, Málaga, Granada, Zaragoza, and Badajoz were the most important. This period coincided with the revival of Christian activity in the north, and in its disorganized condition, Spanish Islam was unable to resist the onset of the Christian Reconquest. Furthermore, because of local jealousies, some of the *taifas* allied themselves with Christian neighbors against their coreligionists and thus facilitated Christian recovery.

Eventually, the Christian successes led to new invasions from North Africa. In 1085, the fall of Toledo caused some of the *taifa* rulers to invite Yusuf ibn-Tashfin, of the Berber Almoravides, into Spain. He came and inflicted a great defeat on the Christians, but proved unable to accomplish any permanent unification. Following the disintegration of the Almoravide conquests, another Berber tribe known as Almohades invaded Spain in 1147 and reduced the *taifas* again, but, after a defeat by Christian forces in 1212, the Almohade empire also disintegrated and the Spanish Mohammedans were left alone to fend off Christian attacks.

**Reconquest and New Christian Kingdoms.** Following the fall of the Visigothic kingdom, some of the survivors—bishops, nobles, and the remnants of the army—gathered in the Asturian mountains near Oviedo and managed to hold off the victorious Arabs. Because their economic and political interests drew them to the center and south of the peninsula, the Mohammedans tended to withdraw from the extreme northern frontier and thus the tiny kingdom of Asturias not only continued to survive, but, without much opposition, even managed to expand to a somewhat shifting frontier just south of the Duero. In the next two centuries, Navarre and Aragon made their appearance, and the capital of Asturias was moved farther south to León as a base for additional conquests. Charlemagne had brought the northeast corner of Spain under Frankish control, but by 874 Wilfred of Barcelona is supposed to have become independent and thus inaugurated the history of the county of Catalonia.

The tenth century was marked by the establishment of an eastern salient of León, subsequently known from its numerous fortifications as the county of Castile. During the rule of the redoubtable Count Fernán González (930-970) a permanent capital was set up at Burgos, and the autonomy of Castile was recognized by the kings of León. The emergence of this new state was an important development; henceforth, it was to be the most active agent in the recovery of new lands, and eventually was to absorb the parent state of Léon itself. However, as the tenth century drew to a close, it seemed that the future of a united Spain lay with Navarre rather than with Castile.

Navarre was probably founded during the wars between the Franks and Basques; in 1000 it came under the rule of Sancho the Great (970-1035). Taking advantage of the growing weakness of the caliphate, Sancho interfered successfully in the neighboring realms, and by 1029 he had united all the Christian states of the peninsula under his control. However, this union was premature. Navarre was too small to hold so great an expanse, and the spirit of local independence was still too strong. Sancho himself so little understood what he had accomplished that on his death in 1035 he divided his territories among his sons, at the same time raising both Castile and Aragon to the rank of kingdoms. The death of Sancho the Great forms a convenient dividing line in Spanish history. For one thing, it marked the beginning of the independent histories of Aragon and Castile and inaugurated the growing supremacy of the latter over León. In 1037, Sancho's son, Ferdinand I of Castile (1035-1065), overwhelmed León and united the realms which thereafter were separated only briefly. Another im-

*CONQUEST OF SPAIN BY THE MOORS AND RECONQUEST BY THE CHRISTIANS UP TO 1150 A.D.*

portant change after Sancho's death was the intensification of the Reconquest, vitalized by a growing religious fanaticism.

While, prior to the eleventh century, wars between Mohammedan and Christian states had been frequent, there had also been periods of peace, with considerable intercourse between the followers of the two faiths. During the *taifa* period, Arabs and Christians had often been allies against common enemies. During the reign of Sancho, members of the great monastic order of Cluny began to enter Spain, where they soon won a reputation for piety and religious zeal. The religious revival they introduced expressed itself in an increasing hatred for the infidel. The period of the Spanish crusades had arrived. In addition to religious motives, the increase in population and consequent land shortages probably helped to turn the Christian kings and nobles southward against Spanish Islam.

BURTON HOLMES FROM EWING GALLOWAY

Under Alfonso VI (1065-1109), Castile enjoyed many triumphs. Toledo fell in 1085, Valencia in 1094, after a nine month's siege in which the famed el Cid Campeador commanded the attacking forces. The Almoravide invasion recovered Valencia in 1098, but most of the other conquests held firm. A period of anarchy followed Alfonso's death, marked only by the establishment of the kingdom of Portugal; then, in 1144, Alfonso VII (1109-1157) resumed the offensive and pushed the frontier farther south. His grandson, Alfonso VIII (1158-1214), made additional conquests, and, with the help of León and Navarre, he was able to win the great battle of Las Navas de Tolosa in 1212, from which the Mohammedan military power never recovered. Ferdinand III (1217-1252), better known as San Fernando, practically completed the work of recovery. He captured Córdoba in 1236, Murcia in 1241, and Seville in 1248. Except for a few isolated conquests, the Castilian crusades lapsed until revived by Isabella in the fifteenth century.

Meanwhile, Aragon was expanding, not only along the southeastern coast, but also overseas. The great conquests began in 1118, when Alfonso I captured Zaragoza, and concluded in 1238 with the surrender of Valencia to James the Conqueror. The conquest of Murcia by Castile abruptly limited the southern expansion of Aragon, but James (1213-1276) had already acquired the Balearic Islands during 1229-1235, thus inaugurating Aragonese imperialism in the Mediterranean. James' son, Pedro III (1276-1285), conquered Sicily in 1282, and Sardinia was acquired early in the next century.

The wars of the Reconquest were destined to have a profound effect on the history of Spain. The centuries of fighting an enemy of another faith intensified the religious feelings of the people and helped to develop a fanatical unity of religion and patriotism which was long characteristic of Spain. Furthermore, the vigorous and continued existence of individual states strengthened the tendencies of disunity and separatism already fortified by Spanish geography. Another result was the stimulation of a desire for wealth and power in the Spanish people, which continued well into the colonial period.

**Castile and Aragon.** Since feudal institutions passed from France into all the Spanish kingdoms, the monarchies in both Castile and Aragon developed along feudal lines. Thus the kings were served by vassals, who assisted them in peace and war, and, in return, received lands and favors. Although the kings in theory were supreme, this supremacy was often limited to their own estates; on lands belonging to the church or to the great nobles, the crown was likely to be weak. Wars between the crown and the nobility were frequent. Until the twelfth century, most of the Spanish people consisted of agricultural laborers in varying degrees of enserfment, but during the eleventh century, with the general European trade revival, a definite mercantile class appeared. As in France and England, the rise of this class in Spain was simultaneous with a great increase in the number of towns, and by the end of the twelfth century, in León at least, the townspeople were recognized as a definite order in the state. It had long been the custom for the king to call the nobles and prelates to the court to render advice on important problems. Such a council at Nájera in 1137 was called a cortes, and the name, used thereafter for such gatherings, eventually became the official title, of the national legislative body. At a cortes held in León in 1188, the representatives of towns were admitted for the first time; later, they became the most important element in such meetings. While at first intended as an advisory and petition-making body, the Castilian Cortes eventually obtained important financial powers as well, and, until the middle of the sixteenth century, often showed remarkable independence in dealing with the royal authority. In local affairs, the towns were usually conceded almost complete freedom by the charters, or *fueros,* which the crown bestowed upon them.

While the Castilian crown had its difficulties with its unruly nobility, as long as the frontier existed the kings were

often able to divert the excess energy of ambitious lords in that direction. However, the slackening of the Reconquest after the death of Ferdinand III, plus the weakness of certain later monarchs, produced near anarchy during most of the fourteenth and fifteenth centuries. Alfonso X (1252-1284) was celebrated for his learning, which earned him the nickname *el Sabio* (the Learned), but he was lamentably weak in dealing with the feudality. During the fourteenth century, only Alfonso XI (1312-1350) was able to maintain his royal rights. After his death, civil war and the accession of a new and unstable dynasty in the person of Henry of Trastamara still further strengthened the nobles' position. The reigns of John II (1406-1454) and Henry IV (1454-1474) marked the almost complete abasement of royal power, and the anarchy of the great nobles continued unchecked.

In Aragon, likewise, the end of the Reconquest complicated the position of the monarchy. Royal authority had always been considerably more limited than in Castile, and, through the Aragonese Cortes, the nobility, and especially the merchant class of Catalonia frequently rebuked monarchs who dared to exceed their constitutional privileges. The situation was further complicated by the *justicia* or chief justice, who was actually above the king in judicial matters and frequently acted as mediator between the crown and the nobility. Toward the end of the thirteenth century, the barons of Aragon were able to force the crown to recognize their rights in a document called the *General Privilege.* This was reaffirmed in 1287 by Alfonso III (1285-1291) in the famous *Privileges of the Union,* which gave official recognition to a league of nobles called the Union. A climax was reached during the reign of Pedro IV (1336-1387), who was more than a match for the nobility in craft and violence. Open war broke out, and in 1348, at the battle of Epila, Pedro completely crushed the opposition. The Union was dissolved, and henceforth the tendency was toward absolutism and centralization; nevertheless the *General Privilege* still remained, and royal authority in Aragon never possessed the extensive powers which, in theory at least, were enjoyed by the crown of Castile. A change of dynasty in 1410 brought a branch of the House of Trastamara to the throne of Aragon, thus helping to pave the way for the final union of the two states under Ferdinand and Isabella. The next two kings, Alfonso V (1416-1458) and John II (1458-1479), were far abler than their Castilian contemporaries, John II and Henry IV, and successfully defended the royal prerogatives.

During this period, both monarchies had serious racial minority problems resulting from the presence of large numbers of Jews and Mohammedans. Although there was no clear-cut policy with regard to either, considerable popular opposition to both groups developed during the fifteenth century, with numerous outbreaks of mob violence. There was still some Arabic influence in the arts, literature, and possibly music, but French influences predominated. Gothic architecture was introduced, and Flemish methods in painting may have been brought to Spain by the Van Eycks. As for social conditions, Castile continued to reduce serfdom, but the crown in Aragon was able to do little to improve the condition of the rural masses. In addition to agriculture and trade, grazing became a very important industry. In Castile, the grazers were organized in a powerful guild called the *Mesta,* which frequently won for them favors from the crown that were prejudicial to the rights of the farmers.

**Spain as a Great Power.** The period of anarchy in Castile was ended by the accession of Isabella I (1474-1504). This princess was a daughter of John II by his second wife, and hence a half sister of Henry IV. Carefully brought up by her mother, she was devout, deeply conscious of her responsibilities, as well as able and determined. In 1469, she married Prince Ferdinand of Aragon (1479-1516), her equal in intelligence and probably her superior in craft, but far below her in piety. Although Isabella's rights to the crown of Castile were contested by her half brother, and actively opposed by Portugal, she was generally accepted as queen when Henry IV died in 1474 without male heirs. Portugal's opposition ended in defeat in 1476. The union of the two states was purely a personal one, based on the marriage of the two rulers; neither ruler interfered in the internal affairs of the other kingdom, and except for the Inquisition, there were no institutions common to each.

Isabella's reign in Castile was marked by numerous reforms. To check the depredations of the nobility, the queen reorganized the administration of justice, and in 1476 she established a rural constabulary to put down disorder. By the Act of Resumption in 1480, the nobility were forced to give up lands and pensions improperly obtained from the crown. Restrictions on castle building still further weakened the

*THE ROYAL PALACE, MADRID, BUILT ON THE SITE OF AN OLD MOORISH ALCAZAR*

EWING GALLOWAY

position of the feudal lords. To provide the crown with adequate administrative help, the Council of Castile was reorganized with increased powers and additional personnel from the middle class. This body soon became the principal administrative organ of the state, assisting the crown in virtually all aspects of administration. To insure religious unity, the Holy Inquisition was established in 1478, with special church courts and investigators to suppress heresy. Although administered by the clergy, the Inquisition was directly con-

COURTESY OF THE NEW YORK PUBLIC LIBRARY

trolled by the crown; the rigor of its methods, and the severity of its sentences, publicly carried out in the auto-da-fé, soon made it one of the strongest weapons employed by the government. In matters of foreign policy and war, Isabella's greatest achievement was the conquest of the last Mohammedan state of Granada in 1492. As a result of her sponsorship of Christopher Columbus she became the founder of the Spanish colonial empire (*q.v.*).

The situation in Aragon, where opposition to royal power was well entrenched, was less favorable to reforms, and Ferdinand did not attempt many. However, in foreign affairs, his reign was a brilliant success. Not only is he entitled to credit for Castile's successful wars against Portugal and Granada, but he was also responsible for the seizure of Spanish Navarre, the Spanish conquest of Naples, and the complete frustration of French ambitions in southern Italy.

After the death of Isabella in 1504, of Philip I in 1506, and of Ferdinand in 1516, the Spanish crowns of Aragon and Castile went to Charles I (1516-1556), son of Philip I and Isabella's daughter, Juana. In 1519, as Charles V, he was elected Holy Roman Emperor in succession to his grandfather, Maximilian I, and found himself ruler of Spain, Naples and Sicily, the Hapsburg territories in the Low Countries (Belgium and the Netherlands), Austria, and the Spanish colonies in the New World. Spain had become a world power, and Charles was the most powerful sovereign in Europe. During his reign, Spain became deeply involved in questions of little immediate interest to it, although of great importance to Hapsburg *weltmacht*. Consequently, Spanish wealth and Spanish soldiers were used to fight the Lutherans in Germany, the Turks in the Mediterranean, and the French in Italy and the Rhineland. Charles failed to halt the advance of the Turks, and he was unable to prevent the establishment of Lutheranism in Germany. He was more successful in promoting church reforms which culminated in the Council of Trent, 1545-1562. His wars with France began with victories but ended in a stalemate. He made few changes in Spanish administration, and, after the difficulties of the early years of his reign, became popular as a monarch.

On Charles's abdication in 1556, his Austrian holdings went to his brother Ferdinand; however, the greater part of his realms passed to his son Philip II (1556-1598). Philip had been brought up in Spain, and, in spite of his Germanic heritage, was regarded as a true Spaniard. Not so bold as his father, he was cautious and plodding, and was convinced that he was chosen by God to assist in the eventual triumph of Catholicism. However, much of his long reign was marked by failures. His policies in the Low Countries, which resulted in unrest and rebellion, helped to bring about the birth of the Dutch republic. His efforts to bring England into the Hapsburg sphere of influence were equally unsuccessful. Finally, in 1588, goaded into action by the depredations of English seamen on Spanish commerce, and Queen Elizabeth's assistance to the Dutch, he dispatched the famous Spanish Armada in an utterly disastrous attempt to effect a landing on the English coast. His intervention in the French religious wars probably prevented a Huguenot from becoming king of France, but, when Henry IV became a Catholic, Philip was forced to accept the fact and withdraw his armies. He was more fortunate in his acquisition of Portugal in 1580 through inheritance, and in his great naval victory in 1571 over the Turks at Lepanto, which temporarily checked Ottoman naval power.

Internally, Philip kept the same administrative system as his father, with the accent on paternalism and centralization, although frequently his plans suffered from the slowness of Spanish administration. The dreaded Holy Office of the Inquisition continued in power. The Cortes was summoned as

*SPANISH STATES AND PORTUGAL IN 1492*

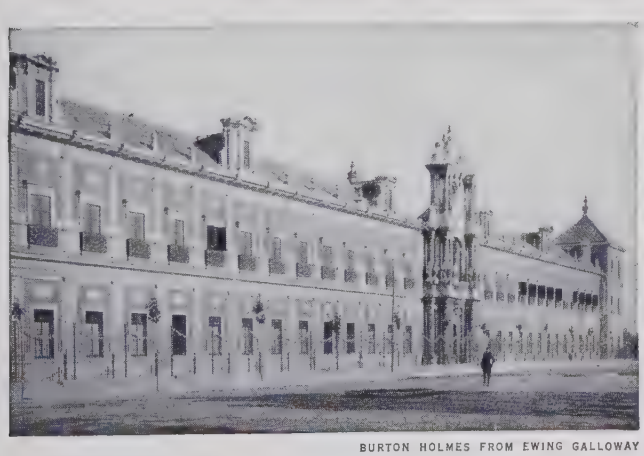
seldom as possible, and during the last decade of Philip's reign the stubborn Aragonese were forced to accept a modification of their celebrated liberties in the interest of increased royal authority. A Mohammedan uprising in 1568-1571 greatly alarmed the government and led the king to adopt a policy of severity in dealing with religious minorities. Henceforth, compulsory conversions were the order of the day.

**Decline of Spanish Power.** Although Spain was still considered a great power after the death of Philip II, internally a serious decline had already set in. The fact was that the international ambitions and commitments of the House

of Hapsburg had strained the resources of the country to the breaking point. Although the revenues of the kingdom, augmented by the income from the colonies, were enormous by sixteenth century standards, Charles V left huge debts, and Philip II was forced into bankruptcy in 1557, and again in 1575. By the end of his reign, taxation was ruinous and the government was still unable to balance expenditures with income. Furthermore, business conditions suffered from an adverse trade balance and the unwise financial policies of the government. The tremendous influx of bullion from the New World had the effect of raising prices in Spain considerably above the general European level, so that while Spain was a good country to sell to but it was a poor one from which to buy. One of the principal sources of government income, a sales tax of 10 per cent, also helped to complete the ruin of the domestic economy. As a result, the rapid decline of almost every sort of production made it increasingly difficult for the state to meet its commitments as a world power.

The reigns of Philip III (1598-1621) and Philip IV (1621-1665) failed to improve these conditions. The former made peace with England in 1604 and signed a twelve-year truce with the Dutch in 1609, but, in spite of peace, he continued to spend large sums on his favorites and on amusements. In 1618, a dispute broke out between Emperor Ferdinand II and the Bohemian Protestants which marked the beginning of the conflict known as the Thirty Years War (1618-1648). Spain entered the struggle because of a desire to help the Austrian Hapsburgs, advance the Catholic faith, and recover, if possible, the Dutch provinces. Philip III died in 1621, but his policies were continued under his son Philip IV. At first, Spain had some successes under its great general, Ambrogio di Spinola, but after 1630 met nothing but disaster. Both Portugal and Catalonia revolted in 1640, and, in order to reduce the Catalan rebels, the Portuguese were neglected and were able to recover their independence. In 1648 there was a general peace, although Spain continued to fight France unsuccessfully until the Peace of the Pyrenees in 1659.

The only bright spot in the general decay was in literature and the arts. During the sixteenth and most of the seventeenth century, the intellectual life of the nation flourished. Salamanca and Alcalá were still recognized as leading European universities. El Greco (c.1548-c.1625), Velázquez (1599-1660), and Murillo (1617-1682) revealed the glory of the Spanish school in painting and were among the great European artists. Literature produced the incomparable Cervantes (1547-1616), whose novel *Don Quixote* is the common possession of all Western nations. In drama, the plays of Lope de Vega (1562-1635) and Calderón (1600-1681) were enormously popular, and, translated into French and German, influenced a great number of European dramatists.



BURTON HOLMES FROM EWING GALLOWAY

*The Palacio de San Telmo at Seville dates from the seventeenth century when it was used as a naval college. It is now a theological seminary.*

The reign of the sickly and neurotic Charles II (1665-1700) completed the decline of the Hapsburg rule of Spain. Following his death without heirs, the crown went to a Bourbon French prince, Philip, duke of Anjou, grandson of Louis XIV, and great grandson of Philip III. In spite of the War of the Spanish Succession, in which France and Spain opposed England, the Netherlands, and the Holy Roman Emperor, Philip V (1700-1746) maintained his throne with only the loss of the southern Netherlands, Gilbraltar, Naples, and Sicily. The accession of the Bourbon dynasty (1700-1931) brought some improvement; a less grandiose foreign policy was followed, and great efforts were made by the crown to improve economic conditions. Both Ferdinand VI (1746-1759) and Charles III (1759-1788), the ablest kings of the century, were also successful in preventing further losses to the empire both in Europe and overseas. As a consequence of Spain's support, France, by a secret treaty in 1763, transferred the vast Louisiana Territory in North America to Spain. Forty years later the territory, after having been retroceded to France in 1800, was sold by Napoleon to the United States.

**Further Decline.** The foolish and incompetent Charles IV (1788-1808) was completely helpless in the face of the great problems created by the French Revolution. Although Spain in 1793 joined the other European powers in war with France, it was forced to make peace two years later, and henceforth was definitely within the French orbit. Napoleon used Spain as a pawn in his wars against England and in his plans for conquering Portugal. However, finding King Charles slow to comply with his demands, he forced him to abdicate in 1808 and awarded the crown of Spain to his brother Joseph. Joseph's reign was short. Napoleon's military occupation of Spain and his attempt to force a monarch on the people provoked a popular uprising. Aided by Spanish guerrilla forces, British troops under Sir Arthur Wellesley, later the Duke of Wellington, defeated the French in a series of bloody engagements, and by 1813 had driven them from the peninsula.

After the fall of Napoleon, Charles's son, Ferdinand VII (1814-1833), was recognized as king, and it seemed that a new era was about to dawn. However, Ferdinand VII was violently opposed to the trends in Spain since 1789. A liberal, although somewhat impractical constitution, had been drawn up in 1812 by the Spanish leaders opposing King Joseph. Ferdinand had accepted it before returning to Spain, but once assured of his crown he violated his promise and directed a violent reaction against all liberal elements. An effort to force him to accept the constitution of 1812 failed when France intervened in 1823 to re-establish him in absolute power.

The remainder of the nineteenth century in Spain was a dreary chronicle of intrigue, chaos, and the failure of reform. Following the death of King Ferdinand in 1833, the succession of his daughter Isabella II was contested by her uncle Don Carlos, provoking the Carlist civil wars from 1833 to 1839. The final success of the queen failed to produce any improvement, for she proved to be completely devoid of responsibility or moral sense. Until her expulsion from Spain in 1868, the government was largely controlled by military cliques. Following her dethronement, the crown

was offered to Amedeo of Savoy, son of Victor Emmanuel II of Italy, but, as King Amadeus I, he soon found the situation completely impossible and abdicated in 1873. A brief and unhappy republican interlude, 1873-1874, convinced the army that only a restoration of the monarchy could put an end to domestic strife, and, consequently, on Christmas Eve of 1874, General Martínez de Campos proclaimed the son of Isabella king, as Alfonso XII. The republic collapsed.

ALFONSO XIII, KING OF SPAIN

CULVER SERVICE

Alfonso (1874-1885) proved a satisfactory if uninspiring monarch. A regime of pseudo-constitutional government was introduced with the Constitution of 1876, which appeared to provide the machinery for a more democratic government. However, such a system was incompatible with the backward masses of the Spanish people. Actually, elections were manipulated by the Home Office to produce any result desired by the coalition of nobility, church, and army, which was actually controlling Spain; an understanding between the leading politicians assured a constant rotation of Liberal and Conservative prime ministers. Alfonso's death failed to produce any crisis in the succession, since the queen soon gave birth to a son who was to become Alfonso XIII (1886-1931). Until 1902, the queen acted as regent.

Although the government was reactionary and corrupt, conditions in nineteenth century Spain were not entirely stagnant. Actually, important changes were slowly taking place beneath the surface. Largely sponsored by foreign capital, the industrial revolution was making a belated appearance in Catalonia and Asturias. The failure of the government to improve conditions affecting the peasants and workers led to the growth of protest movements. The Socialist Party was founded by Pablo Iglesias in Madrid in 1879; the Anarchists had already established themselves in Barcelona. In 1888, the Socialists founded a general trade union known as the U.G.T. *(Unión General de Trabajadores),* and in 1910 the Anarchists sponsored the C.N.T. *(Confederación Nacional del Trabajo),* which was somewhat similar. Although the U.G.T. tended toward legal constitutional methods, while the C.N.T. often resorted to violence, both groups used the strike technique. During the latter part of the nineteenth century, the Anarchists acquired a foothold in the countryside, especially in Andalucía. Meanwhile, two ancient institutions, the crown and the church, declined considerably in prestige, the latter especially losing ground in popular support. Another important development resulted from the Spanish-American War in 1898, and the loss of the last Spanish colonies. Important writers, such as Pío Baroja, Ángel Ganivet, Joaquín Costa, and Ortega y Gasset, were shocked into activity by this defeat and began a searching criticism of Spanish institutions and politics.

**End of Monarchy.** No great changes marked the accession of Alfonso XIII, although the king showed a definite tendency to interfere in politics. During World War I, Spain's neutrality proved profitable, and the middle and upper classes were greatly enriched. However, a depression set in after the war and discontent grew. Following a military disaster in Spanish Morocco in 1922, which was attributed to a blunder by the king, a dictatorship was established by General Primo de Rivera. Undoubtedly this saved the monarch from a personal humiliation. From 1922 to 1929, Rivera, with royal support, governed the country and was able to accomplish a few reforms. However, his regime was increasingly unpopular, and in 1929 he was finally dismissed by the king. For fifteen months Alfonso fought to preserve his throne, but one by one his most important supporters left him. Following local elections in which all but four provincial capitals elected Republican candidates, the army and the Civil Guard withdrew their support of the crown, and on Apr. 14, 1931, Alfonso XIII, without abdicating, left the country.

**Second Republic.** The Spanish Second Republic had a checkered history from 1931 to 1939. A Republican-Socialist coalition controlled the government for two years and attempted numerous reforms in education, religious affairs, finances, and agriculture. Autonomy statutes were drafted for Catalonia and the Basque provinces. However, failure to solve the agrarian problem lost the government its peasant support, and its religious policy alienated many of the upper classes. Attacked by both Left and Right, it was defeated in the 1933 elections and was succeeded by a conservative coalition of Right parties under Gil Robles. This group, in turn, was defeated because of its reactionary policies and its bloody suppression of a revolt in Asturias in 1934. In 1935, moderate and Left parties formed the Popular Front which drove the conservatives out of office in the elections of February 1936.

**Civil War.** During the next few months Spain seemed about to dissolve into chaos as gunmen of both the extreme Left and Right shot it out in the streets. On July 17, 1936, civil war began as a group of generals led by Francisco Franco, Emilio Mola, Sanjurjo, and others started revolts against the government in various cities and in Spanish Morocco. From the beginning, the rebels were supported by large elements of the clergy, nobility, and army, as well as the various Spanish fascist parties. In addition, they quickly received large supplies of materials and men from Germany and Italy, which suggests that they had received promises of foreign support in advance of the uprising.

The civil war lasted about three years, and large areas of the country were devastated. The struggle assumed an international character as men of almost every nationality came to Spain to take part in the struggle for or against fascism. However, because of the efforts of England and France to prevent the Spanish conflict from extending beyond the Spanish borders, most outside aid for the Popular Front government was shut off by the nonintervention policy of the democratic powers; and, in spite of the support of most of the population, as well as the moderate and Left political parties, the republic fought a losing battle against the assist-

ance that Hitler and Mussolini give to Franco and his associates. By the spring of 1939, the organized Popular Front resistance had practically ceased, and General Franco became the dictator of a totalitarian state.

Following his victory, Franco aligned himself with the dictators who had made his success possible. On Mar. 27, 1939, he joined Germany and Italy in the Anti-Comintern Pact, and the Spanish press soon began attacks on the democracies, especially the United States. The idea of Hispanic unity was stressed in Franco's propaganda in Latin America, and everything possible was done to undermine the Good Neighbor policy of President Franklin D. Roosevelt.

*ARMORED CARS AND TANKS MOVING INTO BILBAO AFTER ITS CAPTURE BY THE SPANISH INSURGENTS UNDER GENERAL FRANCISCO FRANCO IN 1937*

WIDE WORLD

**World War II and After.** During the early years of World War II, Spain openly favored the Axis. Through the co-operation of the Falange, which had numerous branches in Latin America, the Axis was able to carry on an intensive propaganda against the democracies in the Spanish-speaking countries of the Western Hemisphere.

However, Spanish assistance to the Axis powers, particularly Germany, was not confined to propaganda. Actually, in spite of its neutrality, Spain was able to render considerable military and economic assistance during the period from 1939 to 1943. Late in 1941, the Blue Division of Spanish troops was organized on a "voluntary" basis and sent to Russia to assist Germany in fighting the "Red peril." At its height, this force probably numbered from 17,000 to 18,000 men, but by the end of 1943, when it began to be withdrawn because of Allied pressure, it had been reduced to approximately 3,500 men. Its military value apparently had been negligible.

In Spain itself, numerous and active Axis agents received full co-operation from the Spanish police. Although constant protests were made by the United States and Great Britain, these agents were given practically a free hand to carry on their espionage work. In spite of the government's promise on May 2, 1944, to begin the expulsion of known Axis agents, many of them were still in Spain when the war ended. In addition, German and Italian vessels often obtained illegal entry to Spanish ports, although complaints from the United States and England tended to restrict this practice after 1943. In the economic sphere, Spain supplied the Axis nations, especially Germany, with food, hides and skins, woolens, and certain strategic raw materials such as wolfram, iron ore, and mercury. Also, Hitler presented Franco with a bill of 374,000,000 reichsmarks for the services of the German Condor Legion in the civil war, and thus Spain was made to assist in the financing of the war against the Allies.

Despite close contacts with the Axis nations, however, Spain was able to stay out of the war. This was partly because of Franco's unwillingness to go to war, and partly because of Hitler's doubts about Spain's military effectiveness, but pressure from the United States and Great Britain also was instrumental in keeping Spain neutral. Spain's acute need of oil, which Germany could not supply, eventually proved a powerful weapon in the hands of the democracies. By threatening to place an embargo on petroleum shipments to Spain, the Allies were able to force Spain to sell them valuable war materials that otherwise would have gone to the Axis.

During the Potsdam Conference following the collapse of Germany, the Allies made it clear that Spain would be allowed no part in the remaking of Europe, and on Feb. 8, 1946, Spain was excluded from the United Nations. Later, when Franco executed ten Spanish republicans who had also fought in the French underground during World War II, there was a violent outcry in France, and on Feb. 28, 1946, the French government was forced to close the Hispano-French frontier. On March 4, Great Britain, France, and the United States publicly announced that they hoped to see the retirement of Franco and the formation of an interim government pending the establishment of one by the free choice of the Spanish people. Shortly afterwards, Poland, supported by the Soviet Union, openly attacked the Franco regime in the United Nations, and on June 1, a subcommittee of the United Nations brought in a report which held that the dictatorship in Spain constituted a potential threat to peace.

However, it soon was apparent that the opponents of

## RULERS OF SPAIN

| Dates of Reign | | Name of Ruler | Succession | Born | Died |
|---|---|---|---|---|---|
| | | | **THE GOTHIC KINGDOM** | | |
| 414 | 415 | Ataulphus (Atawulf) | Brother-in-law of Alaric I, leader of the Visigoths; invaded Spain and founded the Gothic (Visigothic, or Western Gothic) kingdom; assassinated by Sigeric | ? | 415 |
| 415 | 415 | Sigeric | Usurped throne; assassinated 7 days later | ? | 415 |
| 415 | 419 | Wallia | Elected king | ? | 419 |
| 419 | 451 | Theodoric I | Son of Alaric I; killed at the Battle of Châlons-sur-Marne | ? | 451 |
| 451 | 453 | Thorismond | Eldest son of Theodoric I; murdered by brother, Theodoric II | ? | 453 |
| 453 | 466 | Theodoric II | Son of Theodoric I; murdered by brother, Euric | 426 | 466 |
| 466 | 484 | Euric | Son of Theodoric I | ? | 484 |
| 484 | 507 | Alaric II | Contracted to Theudegotha, daughter of Theodoric, Ostrogothic king of Italy, 495; killed in battle, 507 | ? | 507 |

| 955 | 967 | Sancho I the Fat | Younger son of Ramiro II; poisoned | ? | 967 |
| 967 | 982 | Ramiro III | Son of Sancho I; aunt, Doña Elvira, was regent; Ramiro killed in a revolt of the Galicians | 962 | 982 |
| 982 | 999 | Bermudo II | King of León; grandson of Fruela II | ? | 999 |
| 999 | 1027 | Alfonso V | Son of Bermudo II; Gonsalvo his guardian and regent; killed at Viseu | 994 | 1027 |
| 1027 | 1037 | Bermudo III | Son of Alfonso V; León annexed to Castile, 1037; killed in battle against his sister's husband, Ferdinand I | 1016 | 1037 |
| 1037 | 1065 | Ferdinand I (Fernando) | Son of Sancho III of Navarre, king of Castile; received Castile in division of his father's states and founded the kingdom, 1035 | ? | 1065 |
| 1065 | 1109 | Alfonso VI the Valiant (Alfonso I of Castile) | Son of Ferdinand I; received Asturias and León; united with Castile, 1072-1109 | ? | 1109 |
| 1109 | 1157 | Alfonso VII the Emperor | Grandson of Alfonso VI; king of Galicia; continued the Castilian title | ? | 1157 |
| 1157 | 1158 | Sancho III | Son of Alfonso VII; king of Castile | c. 1130 | 1158 |
| 1158 | 1214 | Alfonso VIII | Son of Sancho III; acceded when an infant | ? | 1214 |
| 1214 | 1217 | Henry I (Enrique) | Son of Alfonso VIII; sister, Berengaria, regent | c. 1207 | 1217 |

**RULERS OF SPAIN (*Continued*)**

| *Dates of Reign* | | *Name of Ruler* | *Succession* | *Born* | *Died* |
|---|---|---|---|---|---|
| 1217 | 1252 | Ferdinand III the Saint | Son of Alfonso IX, king of León; inherited Castile from mother; on death of father, joined León and Castile into one kingdom | 1199 | 1252 |
| 1252 | 1284 | Alfonso X the Learned | Son of Ferdinand III | 1221 | 1284 |
| 1284 | 1295 | Sancho IV el Bravo | Second son of Alfonso X | 1258 | 1295 |
| 1295 | 1312 | Ferdinand IV | Son of Sancho IV; mother, Maria della Molina, was regent | c. 1286 | 1312 |
| 1312 | 1350 | Alfonso XI | Son of Ferdinand IV, king of Castile; died of plague | 1312 | 1350 |
| 1350 | 1369 | Pedro (Peter) the Cruel | Son of Alfonso XI; killed by his brother, Henry of Trastamara | 1334 | 1369 |
| 1369 | 1379 | Henry II (Henry of Trastamara) | Natural son of Alfonso XI | 1333 | 1379 |
| 1379 | 1390 | John I (Juan) | Son of Henry II | 1358 | 1390 |
| 1390 | 1406 | Henry III | Son of John I | 1379 | 1406 |
| 1406 | 1454 | John II | Son of Henry III; uncle, Ferdinand I, of Aragon, resigned regency in 1412 | 1405 | 1454 |
| 1454 | 1474 | Henry IV the Weak | Son of John II | 1425 | 1474 |
| | | | **FOUNDATION OF SPANISH MONARCHY** | | |
| | | | **House of Aragon** | | |
| 1474 | 1504 | Isabella I the Catholic | Daughter of John II, king of Castile; half-sister of Henry IV | 1451 | 1504 |
| 1474 | 1516 | Ferdinand V the Catholic | Son of John II, king of Aragon; married Isabella, 1469; inherited crown of Aragon as Ferdinand II, 1479, thus uniting Spain; regent for Juana from 1506 | 1452 | 1516 |
| | | | **Hapsburg Dynasty** | | |
| 1504 | 1506 | Juana la Loca (the Mad) | Daughter of Ferdinand and Isabella; married Philip, archduke of Austria (Philip I of Spain); inherited crown from Isabella; went insane on death of Philip I; Ferdinand assumed government | 1479 | 1555 |
| 1504 | 1506 | Philip I | Son of Maximilian I; married Juana, 1496 | 1478 | 1506 |
| 1516 | 1556 | Charles I | Son of Philip and Juana (Charles V of the Holy Roman empire); as heir to Netherlands and Spain, amalgamated them when elected to Spanish throne; left Spain to Philip II and retired to a monastery | 1500 | 1558 |
| 1556 | 1598 | Philip II | Son of Charles I | 1527 | 1598 |
| 1598 | 1621 | Philip III | Son of Philip II | 1578 | 1621 |
| 1621 | 1665 | Philip IV | Son of Philip III | 1605 | 1665 |
| 1665 | 1700 | Charles II | Epileptic son of Philip IV; mother, Mariana de Austria, was regent; left realm to Philip, grandson of Louis XIV | 1661 | 1700 |
| | | | **BOURBON DYNASTY** | | |
| 1700 | 1746 | Philip V, duke of Anjou | Second son of Dauphin Louis, son of Louis XIV of France, opposed by Archduke Charles, son of Emperor Leopold I; abdicated January 1724 in favor of son, Louis, who died in August; resumed rule | 1683 | 1746 |
| 1746 | 1759 | Ferdinand VI | Second son of Philip V | 1713 | 1759 |
| 1759 | 1788 | Charles III | Third son of Philip V | 1716 | 1788 |
| 1788 | 1808 | Charles IV | Son of Charles III; abdicated in favor of son | 1748 | 1819 |
| 1808 | 1808 | Ferdinand VII | Son of Charles IV; abdicated under pressure from Napoleon | 1784 | 1833 |
| | | | **FRENCH INTRUSION** | | |
| 1808 | 1813 | Joseph Bonaparte | Elder brother of Napoleon I; ousted on his defeat | 1768 | 1844 |
| | | | **BOURBON DYNASTY RESTORED** | | |
| 1814 | 1833 | Ferdinand VII, restored | Son of Charles IV | 1784 | 1833 |
| 1833 | 1868 | Isabella II | Daughter of Ferdinand VII; mother, Maria Christina, regent until 1840; General Espartero regent then until 1843; Isabella ousted by revolution | 1830 | 1904 |
| | | | **SEARCH FOR A KING** | | |
| 1869 | 1871 | Marshal Serrano y Domínguez, Francisco, duke of Torre | Regent | 1810 | 1885 |
| 1870 | 1873 | Amadeus (Amedeo) of Savoy | Elected by moderates; abdicated, 1873; son of Victor Emmanuel II of Italy | 1845 | 1890 |
| | | | **FIRST REPUBLIC** | | |
| 1873 (4 mos.) | 1873 | Estanislao Figueras y Moragas | Chief of the executive power | 1818 | 1882 |
| 1873 (3 mos.) | 1873 | Francisco Pí y Margall | Chief of the executive power | ? | ? |
| 1873 (3 mos.) | 1873 | Nicolás Salmerón | Chief of the executive power | 1838 | 1908 |
| 1873 | 1874 | Emilio Castelar y Ripoll | Prime minister | 1832 | 1899 |
| | | | **BOURBON RESTORATION** | | |
| 1874 | 1885 | Alfonso XII | Son of Isabella II; died of tuberculosis | 1857 | 1885 |
| 1886 | 1931 | Alfonso XIII | Posthumous son of Alfonso XII; mother regent until 1902; exiled; had appointed Primo de Rivera dictator, 1923-1925 | 1886 | 1941 |
| | | | **SECOND REPUBLIC** | | |
| 1931 | 1936 | Niceto Alcalá Zamora y Torres | President | 1877 | 1949 |
| 1936 | 1939 | Manuel Azaña | President; resigned 1939 | 1880 | 1940 |
| | | | **FASCIST DICTATORSHIP** | | |
| 1939 | | Francisco Franco-Bahamonde | General of the Spanish army; became dictator | 1892 | |

Franco could not agree on what should be done. The subcommittee's report was not accepted, and motions by the Soviet Union and Poland to submit the question to the General Assembly, and to sever diplomatic relations with Spain, were defeated. With the rapid deterioration of the friendship between the Soviet Union and the Western powers, there was less inclination to interfere with a regime in Spain that openly proclaimed itself the bitter foe of communism.

In 1947, by a law passed on March 31, Franco became chief of state for life. The question of a monarchist restoration was evaded by the appointment of a regency council,

pledged to recognize a king of Franco's choosing in case of the death or incapacity of the caudillo.

Improvement in international relations was indicated by the reopening of the Hispano-French frontier in February 1948. To bolster Spain's shaking economy, Franco made repeated overtures toward the Western nations, particularly the United States, for aid and for participation in plans for the unity and defense of the West. The United States House of Representatives' approval of Marshall Plan aid to Spain was rejected by President Truman in April 1948. Throughout 1949 and up to Sept. 6, 1950, when the president refused to grant the loan to Spain of $62,500,000 authorized by Congress in the omnibus appropriation bill, the problems confronting the Franco regime remained unsolved—economic aid, membership in the United Nations, and participation in European defense as a signatory of the Atlantic Pact.

As a result of the growing hostility between the free world and the Soviet system, however, United States policy toward Spain was revised, and diplomatic relations were reestablished Dec. 27, 1950, when President Truman appointed Stanton Griffis American ambassador to Madrid. England and France followed suit. Because of Spain's strategic location and its importance to the West in the cold war, Adm. Forrest Sherman visited Franco in July 1951 for important conversations; it was agreed that Spain would not come into NATO but would sign a separate agreement with the United States. In spite of protests from England and France, President Truman in October 1951 signed the foreign aid bill allotting $100,000,000 to Spain for military and economic assistance. In April 1952 Franco further strengthened his diplomatic position when at a conference with Dr. Antonio de Oliveira Salazar, premier of Portugal, it was announced that Portugal considered the Iberian Peninsula a strategic unity. Since Portugal was a member of NATO, this announcement was taken as a strong hint that Spain would have to be included in any agreement between Portugal and the West for the defense of Europe. At the same time, Spanish diplomats were suggesting to the Moslem countries of the Middle East that Spain, because of its Mohammedan background, was particularly fitted to mediate between East and West. In August 1952 both England and France persuaded West Germany to exchange ambassadors with Spain. *See also* SPANISH COLONIAL EMPIRE, THE. J. F. R.

**SPAIN, TREATY WITH** (1819), also known as the Adams-Onís Treaty, defining the western boundary of the United States and providing for the cession of the Floridas by Spain. It was signed at Washington on Feb. 22, 1819, by Secretary of State John Quincy Adams and the Spanish minister, Luis de Onís and was ratified by Spain on Feb. 21, 1821.

Under the terms of the treaty, Spain gave up all claims to both East and West Florida. The western boundary of the Louisiana Purchase was clearly defined for the first time: beginning at the mouth of the Sabine River, the line zigzagged in a northwestward direction to the forty-second parallel, the present northern limit of California, then proceeded directly west to the Pacific Ocean. In effect, Spain transferred to the United States all its claims to the Oregon country. In return, the United States gave up whatever title to Texas it had acquired under the vague terms of the Louisiana Purchase. It also assumed, to a limit of $5,000,000, the claims of its citizens against Spain. Certain tariff privileges were accorded Spanish goods in Florida ports. R. W.

**SPANISH,** a language spoken by most Spaniards and even by Catalans, Basques, and Galicians, who are in general bilingual; it is moreover the official and cultural language of all the Central and South American republics except Brazil. It is spoken in the Spanish colonies, the Philippines, and some southern sections of the United States, and the Ladinos of the Eastern Mediterranean also speak a sort of archaic Spanish. Spanish is spoken on four continents by probably more than 100,000,000 persons.

The history of the Spanish literary language is very similar to that of French: it is the history of the growth and expansion of a local dialect. In the case of Spanish, this dialect was that of Old Castile, in the north, which prevailed essentially because of the political conquests of the Castilian kings, who progressively unified under their command the whole Iberian peninsula with the exception of Portugal. Before that time the Latin inhabitants of the central and southern parts of Spain and Portugal, which were under the domination of Islam, had preserved their Latin character to a greater degree than had those of the less united northern portions of Spain, and they had developed a language called Mozarabe, which is little known, but which was certainly much more archaic than Spanish or Portuguese. The Mozarabic dialects were entirely uprooted and replaced by Castilian and Galician at the time of the Christian reconquest of Spain and Portugal from the Moors, and this sudden and radical linguistic change explains the relatively uniform subsequent character of the language in the southern parts of the peninsula. This spread of Castilian innovations, such as initial *h-* for *f-*, to the south split the old peninsular dialects once extending from Catalonia and Aragón on one side to León and Portugal on the other, and Catalan and Portuguese thus preserve certain archaic features which Castilian has eliminated from the central zone.

The oldest important documents in Spanish are the *Glosas Emilianenses,* composed in the Monastery of San Millán de la Cogolla, in Rioja, and the *Glosas Silenses,* composed in the Monastery of Silos, not far from Burgos. They are notes written on the side of a few homilies and a penitential, and in them the monks translated into their dialect, which was of a Navarro-Aragonese type, the Latin sentences and words they did not readily understand. These documents belong to the tenth century, but a Romance language was certainly spoken long before that in Spain; the first literary text is the famous *Cantar de mío Cid,* composed around 1140, and this was certainly preceded by many other epic poems written in Romance.

The main characteristics of Castilian which differentiate it from other Romance languages are: (1) the diphthongization in almost every position of Latin *ĕ* and *ŏ,* as in *tiempo* and *cuerno,* where Portuguese, Catalan and Provençal do not diphthongize and Italian and French do so only in unchecked syllables, as *viene, vient* and *muore, meurt* (but *tempo, temps; corno, cor*); (2) the change of *-ly-* through *-ž- to -χ-,* as in the shift from *palea* through **palya* to *paja,* where Italian and French have *ʎ,* and then often *y;* (3) the shift of the Latin group *-ct-,* which, after becoming *-it-* as in all Western Romance languages, proceeds further to *č* (written *ch*) as in the shift from *octo* to *ocho* which does not take place in Portuguese, Aragonese, Catalan, Provençal, or French, *č* being therefore a typical Castilian innovation; (4) the passage of *x* to *š* (as preserved in Portuguese) and then *χ,* as

in the shift from *axem* to *eje* or *dixi* to *dije;* (5) the palatalization of initial voiceless consonants plus *-l-* (*pl-, cl-, fl-*) to *ll-* (*ļ*), as in the shifts *plenum* to *lleno, clavem* to *llave* and *flamman* to *llama,* where Portuguese and Leonese have *č-,* French preserves *cl-, pl-, fl-,* and Italian has *ky-, py-, fy-;* (6) the change of the Latin *-mb-,* which is preserved in Mozarabic, Leonese, Portuguese, Galician, and most other Romance languages, except Aragonese and Catalan, to *m* (through *mm*), as in the shifts *palumbam* to *paloma* and *lumbum* to *lomo* (Cat. *llom*), where Mozarabic retains *polombina,* Portuguese *pomba,* and Leonese *palomba;* and (7) the change of *-m(i)n-* to *-mbr-* as in the shift of **hominem* to *hombre.* When *-l-* occurred before a consonant it once became *-u-,* as in the change from *alt(e)rum* to *otro,* but a learned influence then restored the *-l-* in almost every case, as in *alto.*

The Spanish vocabulary contains derivatives of a great many ancient Latin words which have disappeared or changed their meaning in most or even all other Romance countries, retaining, for example, Spanish forms of the Latin *comesse* (*comedo*), *perna, mensa, angustus, metus, formosus, malus, follis, fabulari, materia,* and many others. The Arabic influence was also very strong in Spain, much more than in any other Romance country, and this is clearly reflected in the many Arabic words which remain in Spanish, especially in the fields of administration (*alcalde, alguacil, aldea*), trade (*almacén, arancel, zoco, almoneda*), and construction (*albañil, azotea, azulejo, alcantarilla*). Italian has also exercised a very strong influence on the Spanish lexicon.

Spanish has not changed very much from the times of the Cid, certainly much less so than French and English, though more than Italian. The most significant changes are the passage of *f-* to *h-* (now mute) and the unvoicing of *-z-, -ž-,* and *-ž-,* which therefore fused with *-s-, -θ-,* and *-š-* (once written *x,* now *j,* and pronounced *χ*). Thus Ladino preserves *mužer* and *bašo,* whereas Spanish has *mujer* and *bajo.* Final *-e* was dropped in bi-syllabic nouns, the earlier *pece* now being *pez.* The distinction between *v* and *b* was also eliminated, although it is preserved in Ladino.

American Spanish is not very different from the European variety, but it frequently confuses *c, z* (*θ,* Eng. *th* of *thick*), and *s* in a process known as *seseo,* and aspirates *s* before a voiceless consonant, *hasta* being pronounced *aḥta* and even *atta;* both of these are Andalusian characteristics. In Argentina the lower classes still use the ancient *vos* in respectful address instead of *Usted.* G. B.

**SPANISH AFRICA,** a term applied collectively to all of Spain's possessions in north, west, and central Africa. In fact, Spanish Africa has included all of Spain's overseas territories since the loss of her colonies in the West Indies and the Far East after the Spanish-American War of 1898. The Canary Islands, which form two provinces of Spain proper, are not included in this term, although geographically the islands are united with Africa rather than Europe. Spanish Africa is divided into three districts: (1) Spanish Morocco, including five presidios of Spanish sovereignty, the Spanish Protectorate composed of a northern and southern zone, and the Ifni territory; (2) Spanish Sahara, composed of Saguiet el Hamra and Rio de Oro (the southern zone of Spanish Morocco is sometimes thought of as a part of Spanish Sahara); and (3) Spanish Guinea, composed of Fernando Po, Annobón, Corisco, the Elobeys, and Continental Guinea.

**Administration.** Political and administrative conditions vary considerably in the several parts of Spanish Africa. The five "places of sovereignty" on the north coast of Morocco, also known as the presidios—the two cities of Ceuta and Melilla and the islands of Alhucemas, Chafarinas, and Peñón de Vélez de la Gomera—though integral parts of Spain, are in certain matters governed by the High Commissioner and the Comandancia Militar of Spanish Morocco. The northern and southern zones in Morocco constitute a protectorate, in which the Sultan of Morocco is still nominally sovereign, but they are administered by the High Commissioner, who also administers the Ifni enclave. Spanish Sahara consists of three parts, in only two of which, Saguiet el Hamra and Rio de Oro, is Spain officially sovereign. The third and northernmost part, where Cabo Yubi, the administrative center of Spanish Sahara, is located, is the southern zone of the protectorate of Morocco, where the Sultan of Morocco is nominally supreme. Rio de Oro is a colony, and Saguiet el Hamra, described officially as a "zone of free occupation," must also be regarded as colonial in status. Both are administered by the High Commissioner. Spanish Guinea, including Fernando Po, Annobón, Corisco, and the Elobeys, is a colony and is administered by a governor. *See also* Annobón; Canary Islands; Continental Guinea; Corisco; Elobey; Fernando Po; Guinea, Spanish; Ifni; Morocco; Spanish Sahara. R. G. W.

**SPANISH-AMERICAN WAR** (1898), a conflict between the United States and Spain which had its origin in the Cuban insurrection of February 1895. The ruthless methods used by the insurgents and the Spanish government to achieve victory led to widespread devastation and hardship for the Cubans and losses to American business.

**Background.** Several factors operated to impel the United States toward intervention: (1) *Juntas* of Cuban patriot refugees in the United States kept the flames of revolt alive in Cuba by furnishing arms and supplies to the insurgents and served as centers of propaganda in the United States to enlist American sympathies; (2) William Randolph Hearst and Joseph Pulitzer vied with each other in promoting their newspaper sales by one-sided reporting of the alleged cruelties of the Spanish in suppressing rebellion, thus inflaming American opinion; and (3) public men, including politicians and clergymen, preached a virulent manifest destiny theme that emphasized the mission of the United States in assuming the burden of civilizing backward peoples. President Grover Cleveland and, at first, President William McKinley, supported by the business interests of the country and by some politicians, resisted all pressure for intervention and sought to achieve peace by diplomacy. Following the destruction of the U.S.S. *Maine* in Havana harbor Feb. 15, 1898, McKinley was unable or unwilling to resist the public clamor for war, despite his success through diplomacy in finding a solution to the Cuban problem. On Apr. 11, 1898, McKinley asked Congress for authority to use the military and naval forces of the United States to end hostilities in Cuba. Congress, by a joint resolution, approved on Apr. 20, demanded the recognition of Cuban independence and the withdrawal of Spain from the island, directed the President to use the entire land and naval forces of the United States to accomplish these ends, and disclaimed any intention to exercise sovereignty over Cuba, except for pacification. Spain, upon receiving news of this resolution, broke off diplomatic relations, whereupon the President asked Congress for a declaration of war. On Apr. 25, 1898, Congress by joint resolution declared that a state of war existed between the United States and Spain, beginning April 21.

**Military and Naval Campaigns.** The President on April 22 proclaimed a blockade of certain Cuban ports and on the following day he issued a proclamation calling for

125,000 volunteers. On April 24 Commodore George Dewey, commanding the Asiatic Squadron, received orders to proceed from Hong Kong to the Philippines to engage the Spanish fleet assembled there. Dewey's destruction of the Spanish fleet in the Battle of Manila Bay on May 1, 1898, proved to be the most notable victory of the war and led eventually to the occupation of Manila and the cession of the Philippine Islands by Spain to the United States.

*THE EXPLOSION OF THE UNITED STATES BATTLESHIP MAINE IN HAVANA HARBOR ON FEBRUARY 15, 1898*

FROM THE DRAWING BY W. LOUIS SONNTAG, JR.

COURTESY OF THE NEW YORK PUBLIC LIBRARY

Admiral Pascual Cervera, with the Spanish Atlantic Fleet, evaded the American blockade and entered the harbor of Santiago de Cuba, May 19, 1898. An American fleet commanded by Admiral William T. Sampson blockaded Cervera, while 17,000 regulars and volunteers assembled at Tampa, Fla., for transport to Cuba to co-operate in the capture or the destruction of the Spanish fleet. An expeditionary force commanded by General William R. Shafter landed east of Santiago late in June and on July 1, 1898, stormed the heights of San Juan and El Caney, overlooking Santiago Bay, thus making Cervera's position untenable. The troops included the Rough Riders, recruited by Lt. Col. Theodore Roosevelt and commanded by Col. Leonard Wood. Fleeing the harbor on July 3, the Spanish fleet was destroyed by an American squadron in a short engagement, thereby paving the way for the surrender of Santiago to Shafter on July 14. General Nelson A. Miles began the subjection of Puerto Rico July 25, 1898, while a third army under General Wesley Merritt landed outside of Manila and proceeded, with the aid of Dewey's ships and of the insurgent forces under Emilio Aguinaldo, to invest the city, Aug. 13, 1898.

**Treaty of Paris.** After the capitulation of Santiago, Spain began peace overtures through the French minister at Washington. The two governments terminated hostilities August 12 by signing a peace protocol under which Spain relinquished Cuba, ceded Puerto Rico and one of the Marianas to the United States, and agreed to pay for American occupation of Manila until the peace commission disposed of the Philippines. American and Spanish commissioners arranged terms of peace in the Treaty of Paris, signed Dec. 10, 1898. The United States Senate, following a strong but ineffective attack by the anti-imperialists against the document, ratified the treaty Feb. 6, 1899. The war cost the United States about $250,000,000 and 5,000 lives. There were less than 400 battle casualties; the remainder represented the disease toll. Inefficiency, incompetence, and bungling marked certain phases of the prosecution of the war. Secretary of State John Hay characterized it as "a splendid little war." The war marked the end of Spain's New World empire and the rise of the United States as a major power. G. H. K.

**SPANISH BAYONET.** *See* YUCCA.

**SPANISH BROOM,** a long-blooming shrub, *Spartium junceum,* of the pea family, closely related to, and similar to, the common broom, *Cytisus.* It grows to a height of 10 ft. The flexible green twigs, generally leafless, bear a succession of brilliant yellow, fragrant, pealike flowers. Native to the Mediterranean region, the plant can be grown in the central United States. J. C. Wis.

**SPANISH COLONIAL EMPIRE, THE,** beginning with the discoveries of Columbus and ending with the Spanish-American War of 1898, one of the first and most successful of the early colonial enterprises. During the sixteenth century, when neither England nor France was able to establish a single permanent colony, Spain founded an empire that included Mexico, Central America, South America except Brazil, and numerous islands in both the eastern and western hemispheres. The seventeenth and eighteenth centuries comprised a period of rivalry among the Dutch, British, and French colonial empires. The integrity of the Spanish empire was defended successfully, however, until the end of the Napoleonic Era, when it was destroyed by colonial revolutions.

Columbus' initial voyage of discovery in 1492 was followed rapidly by the establishment of colonies, and for the next fifty years discovery and colonization proceeded concurrently. Within a generation after Columbus, Spaniards had occupied the West Indies, and were exploring the mainland of North and South America from Florida to the Río de la

Plata. In 1513 Panama was crossed and the Pacific Ocean discovered; Cortés reached Mexico in 1519, and the following year Magellan discovered the strait to which he gave his name. With the conquests of Cortés, the base for exploratory activities moved from the West Indies to Mexico, and expeditions into the northern areas followed quickly. De Soto traveled from Florida up to the Carolinas and eventually to the Mississippi in 1539-1540. During 1540-1542 Coronado made the spectacular journey that took him as far north as Kansas, and in 1542-1543 Cabrillo and Ferrelo sailed up the California coast to a point just beyond the present Oregon-California line.

In the exploration of South America, Panama was used as a base; in the 1520's, a few short expeditions were made to the outskirts of the Inca Empire. Between 1531 and 1533 this fabulously rich area was added to Spanish possessions by Pizarro, while the areas of modern Colombia and Bolivia were conquered a few years later. Chile was occupied by Valdivia during the 1540's and 1550's in spite of great opposition from the Indians. The Río de la Plata area had been touched as early as 1516, but little was done to incorporate it into the empire until the founding of Asunción in 1538; henceforth this city served as a base for explorations toward the coast. After an earlier unsuccesful attempt, Buenos Aires was refounded permanently in 1580 by Juan de Garay, and eventually became the most important metropolis of the southern regions. Outside the Americas, Spain occupied the Philippines in 1564-1565; by the end of the century, she had acquired a few small holdings in the Far East and along the African coast.

**Sixteenth Century.** The sixteenth century was also important for the development of colonial institutions and policies. Early colonial problems were assigned by Ferdinand and Isabella to Bishop Juan Rodríguez de Fonseca, but in 1503 a house of trade known as the *Casa de contratación* was established to assist him in the regulation of American emigration and trade. In 1524 the Council of the Indies began to function directly under the Crown as a supervisory and policy-making body for all colonial affairs. In the colonies themselves, the Crown soon recovered the initial concessions made to Columbus, and thereafter jealously guarded its supremacy by making limited grants of land and authority to the various conquistadors. To check the violent rivalries between them, it was soon necessary to establish some supreme colonial authority able to control and to compel respect; consequently, in 1529 the Viceroyalty of New Spain was created, including Mexico, Central America, and the Caribbean. Shortly afterward the Viceroyalty of Peru was instituted including all territory south of the northern viceroyalty. Until the accession of the Bourbon dynasty in the early 1700's, all the Spanish colonies in the New World were grouped under these two major divisions. Under each viceroy, the colonies were governed by various governors and captains-general. Judicial problems, plus additional administrative duties were handled by special courts known as *audiencias,* which numbered fourteen by the end of the eighteenth century.

**Colonial Society.** Spanish colonial society naturally reproduced the most important institutions and social strata of the mother country. Purity of religion was an important factor in colonial life, and the Catholic Church was as powerful and privileged as it was in Spain. Vigor was not wanting in the intellectual activities of the colonies; a printing press was established early in Mexico City, and in time academies, colleges, and universities appeared in the principal cities. The highest rank in colonial society was reserved for officials of Spanish birth; next came Spaniards of wealth born in the colonies; lowest of all were the poor whites, half-breeds, and native Indians. Relations with the Indians presented a difficult problem for the Spanish government. Beginning with Queen Isabella, Spanish sovereigns had insisted that the Indians were not to be treated as a slave class. However, in spite of the official doctrine, colonial practice was to make them practically that. Many Indians were forced to labor in mines, or on estates in various forms of serfdom. The two commonest systems of enforced labor were known as the *encomienda,* and the *repartimiento.* Besides the exploitation of the Indians, Spanish interest centered in mining, especially in gold and silver which was richly distributed throughout Hispanic America; the pastoral industries, agriculture, and commerce also were developed energetically. In accordance with the economic ideas of the time, trade with the colonies was restricted entirely to Spain by law. In spite of this, however, Great Britain, France, and the Netherlands were able to develop a rich smuggling trade with the Spanish colonies during the seventeenth century.

**Eighteenth Century.** The last century of Hapsburg rule in Spain was a period of decline, but the arrival of the Bourbons in 1700 introduced a century of remarkable recovery. In the colonies, this produced successful reforms of colonial institutions, new explorations chiefly in what were later New Mexico, Arizona, and California; and the generally successful defense of the empire against attacks by Great Britain. Although Spain lost Florida to Great Britain in 1763, France ceded the vast Louisiana Territory to her in compensation for the loss and Florida was recovered in 1783. Administrative improvements during the Bourbon period included the establishment of the Viceroyalty of New Granada, 1717, and the Viceroyalty of Río de la Plata, 1776. In addition, to strengthen the northern frontier of the Viceroyalty of New Spain, important cities such as San Diego, Los Angeles, Monterey, and San Francisco were founded. In 1800, by the Treaty of San Ildefonso, Spain returned the Louisiana Territory to France.

**Nineteenth Century.** The American and French revolutions greatly stimulated tendencies toward independence already latent in the colonies, but nothing overt occurred until the Napoleonic period. When Napoleon occupied Spain in 1808 and forced the Spaniards to accept his brother Joseph as king, revolts against the new regime occurred throughout the Spanish colonial world. In the course of a few years, most of these revolts against French control were transformed into movements for colonial independence, and when Great Britain in 1819 indicated her opposition to any re-establishment of Spanish control; it was clear that the empire was gone forever. All that remained were Cuba and the Philippines, and small holdings in the Caribbean, Africa, and the Far East. During the nineteenth century, a powerful independence movement developed in Cuba as a result of the severity and inefficiency of Spanish rule there. Spanish efforts to put down this movement finally involved it in war with the United States in 1898 which resulted in the American acquisition of the Philippines, Guam, and Puerto Rico, and the establishment of Cuba as an independent nation. This marked the end of the once great Spanish colonial empire.

**Spanish Africa.** Although not on the same scale as the vast holdings in the Western Hemisphere, the lands Spain had gradually acquired in Africa were its only overseas possessions in the twentieth century. Spain had invaded Morocco in the early sixteenth century and held several presidios along the coast. In the late nineteenth century Spain invaded northern Morocco in order to expand its holdings inland; at the

same time it intervened in the Sahara. Ifni was ceded to Spain by Morocco in 1860, though occupation was nominal until 1934. Its boundaries, as well as those of Spanish Sahara and Spanish Morocco, were set by treaties with France in 1904 and 1912, though Ifni's area was reduced in 1935. Of the constituent parts of Spanish Guinea, Fernando Po was ceded to Spain by Portugal in 1778; the islands of Corisco and Elobey were annexed in 1846; and continental Guinea, for which Spain claimed an area extending inland to the Ubangi River, had its bounds settled at the Convention of Paris in 1900. *See also* FERNANDO PO; IFNI; MOROCCO; SPANISH SAHARA. **SPANISH FLY,** the name given to the blister beetle, *Lytta vesicatoria,* of the family Meloidae. This species occurs in abundance in parts of Europe, feeding chiefly on ash and privet. When dried and powdered, the Spanish fly has long been used as a blistering agent, and is the chief source of cantharidin, which occurs in the elytra or wing covers. Because blistering, the deliberate use of an irritant to counteract local infection, is little practiced today, the importance of the cantharidin industry has declined greatly. Cantharidin was also used as an aphrodisiac, or love potion. Since its internal use is extremely dangerous, the sale of cantharidin is prohibited by law in many countries.

C. H. Cu.

**SPANISH FORK,** a city in the north central section of Utah, in Utah Co., situated about 60 mi. south of Salt Lake City, 4,570 ft. above sea level, with the Wasatch Mountain range and Spanish Fork peak to the east, Utah Lake to the west, and Mt. Nebo (11,871 ft.) to the south. The city was incorporated in 1855. Spanish Fork is governed by a mayor and council. A local feature is a monument commemorating what is said to have been the first Icelandic settlement in the United States. Transportation is furnished by the Union Pacific and the Denver & Rio Grande Western railroads. Stock and poultry raising are important interests of the region. The farm crops include hay, grains, sugar beets, and vegetables. Local industrial plants include a sugar-beet factory, foundry, packing plant, poultry-processing plant, and plastic factory. Pop. 1950, 5,230.

**SPANISH GUINEA.** *See* GUINEA, SPANISH.

**SPANISH LITERATURE.** Literature in the Spanish language has been for more than eight hundred years the vehicle of expression for the culture of one of the most original peoples of Europe. Although the other languages spoken in the Iberian Peninsula—Portuguese, its medieval antecedent Galician, and Catalan—possess valuable literatures, they nevertheless lack the richness and the sustained continuity of the literature of Castile, the central region, and it was Castilian that became the language preferred for literary purposes by all Spaniards after the sixteenth century.

**Characteristic Aspects.** One of the more peculiar traits of this literature is the relatively limited evolution of its language since the twelfth century compared with the profound transformations experienced by the French or the English languages of the Middle Ages. Thus, a Spaniard familiar with the literary language of today understands the general meaning of a twelfth-century text of the *Cantar de mio Cid,* or the thirteenth-century *Siete Partidas* ("The Seven Divisions") of Alfonso, and between the fourteenth and seventeenth centuries the language, the religion, the thoughts, and the life in general of Spain did not change as markedly as in England, France, or Germany.

In the sixteenth century a number of poetic forms and literary genres of Italian origin penetrated into Spain and may be seen in the theatre of Juan del Encina, the poetry of Garcilaso de la Vega, the pastoral novel of Jorge de Montemayor, and epic poems of the Renaissance type, like *La Araucana* of Ercilla, but medieval epic themes nevertheless continued to live through the *romancero* and the national drama. In other European countries, epic themes continued among the rustic people only. This mixture of new with traditional art and of learned with ingenuous themes gives a spontaneous air to Spanish literature and at times deprives it of reserve and moderation, but it is this very blending which, although it either disturbs or charms foreigners, accounts for the great originality of the literature and the fact that it is always interested in embracing and in expressing the totality of human life. In the theatre of Lope de Vega, for example, there are both aristocratic and plebian personages, tragic and comic elements, the Italian hendecasyllable beside the traditional octosyllable, and complicated metaphors joined to the lowest slang.

In the same way, both religious and worldly themes are interwoven, for in the soul of the Spaniard God and the world are very close. Thus, during the seventeenth century there was a superabundance of religious works, but on the other hand, there were very few scientific writings of a theoretical character. The Spaniard preferred to busy himself with the moral problems of human existence and conduct, and in general, works of literature, history, politics, or religious morality occupied in Spanish life a place which in other countries was shared with science and technology. That which the Spanish are, feel, desire, and think is found in their literary creations rather than in their treatises on science and philosophy.

**The Medieval Period.** We do not properly consider as Spanish the literature written in Latin during the Roman epoch of Seneca, Lucan, Martial, and Prudentius; under the Visigoths during the sixth and seventh centuries when the works of Saint Leander and Saint Isidore of Seville were written; or afterwards. The language is in this case an essential element. As long as the Latin of Rome was a live language which was understood by the inhabitants of the Iberian Peninsula, or until the sixth century of the Christian Era, the Iberian people felt themselves a part of the Roman Empire; when written Latin ceased to be spoken and understood, literature in Latin became only a learned exercise, which had no effect upon the majority of the people. Spanish literature began when the language spoken in Castile was converted, in the eleventh century, to a means of expression for the collective feelings of a people with the consciousness of being an independent unit and not just a part of Rome or of European Christianity.

The *cantares de gesta,* or epic poems, are the oldest works of this sort and already existed in the eleventh century, although the original texts have been lost. Their themes were the struggles of Castile to obtain its independence from the kingdom of León and to demonstrate its individuality in relation to the other Christian regions that opposed the Moors. Of this magnificent poetry we possess the *Poema del Cid,* one fragment of *Roncesvalles,* fragments of other epics preserved in some old ballads of the *romancero,* and the prose versions in the chronicles of the thirteenth century, which used the *cantares de gesta* as historic sources.

This epic poetry of Castile differs from that of the remainder of Europe in its historical fidelity and its geographic precision. The anonymous authors of these epics found it necessary to sing of persons and places known to their public,

for the Spaniard did not care for fantastic narratives when he could have poetry based on the contents of his own experience—his heroes, his wars, his cities, and his fields—in short, something that was within reach of his own life. This method of conceiving and presenting reality in relationship with the experience of the writer and of his public is what is customarily called "Spanish realism." The Cid of the *Poema* is thus a hero gifted with all perfections, but at the same time he is also the modest proprietor of a certain mill, the income from which helps him to live. These epic *cantares* on national themes were cultivated in Castile from the eleventh century until the beginning of the fifteenth century, but after the fourteenth century they become more plebian and rough. The *romancero* was, after the fourteenth century, the genre by which the poetic fancy of the people was expressed.

During the thirteenth and fourteenth centuries another form of verse was also cultivated in Spain. This was the so-called *mester de clerecía,* a learned poetry which treated religious themes as in the lives of saints; the history of antiquity, as in the life of Alexander the Great; or moral subjects, of which the *Libro de buen amor* of the Archpriest of Hita is an example. Unlike Spanish epic poetry, which had unequal lines, the *mester de clerecía* used stanzas of four monorhymed lines of fourteen syllables each and revealed the technique which clerical poets of the thirteenth century had derived from Latin and from the literature of France. Their art, nevertheless, was essentially narrative, and did not express personal feeling before the time of the Archpriest of Hita in the fourteenth century.

Before the end of the fourteenth century Castile did not possess a truly lyric poetry, and this is surprising in view of the fact that such poetry is found contemporaneously in the west in Galicia, in the east in Catalonia, in the north in Provence, and in the south in Arab Spain. But Castile found expression in epic poetry, and this none of the above literatures possessed. This Castilian peculiarity may be explained as a defensive reaction against Moslem Spain, whose poetry reflects all kinds of pleasures and vices, for the grave Castile of those centuries did not cultivate a poetry that would have slackened the heroic tensions of its soul, or that would have delighted itself in the expression of the emotions rather than in the account of brave deeds. Morals, history, and law were, on the other hand, preferred themes, as witness the multitude of works composed or translated in the court of King Alfonso the Wise.

The position of Spain suffered great changes at the beginning of the fifteenth century. Only the Moorish kingdom of Granada now remained to be reconquered, the Christian kingdoms of Spain were on the way to becoming united, and the action of Italian Humanism began to be noted. King Juan II (1405-54) and his nobles now lived in hitherto unknown luxury, and literature also took new directions. Lyric poetry now treated of individual love affairs, as it had previously done in the literature of Provence and Galicia, and of episodes in contemporary life, as in the *Laberinto de Fortuna* of Juan de Mena. A Latinate style was now developed, themes from antiquity came into use, and courtly poetry attained its greatest perfection in the *Coplas* of Jorge Manrique on the death of his father. At the same time, an interest in personal life and in the popular spoken language was reflected in the *Corbacho* of Alfonso Martínez de Toledo, where for the first time popular speech was used as a means of literary expression. A further democratizing influence may be seen in the chronicles of the time, which narrate not only the lives of kings but also those of illustrious contemporary personages, for example, Don Álvaro de Luna, a favorite for many years of King Juan II but later executed by his order.

These works and those of many other authors reveal the growing vitality of Castile during the fifteenth century, and with the publication of *La Celestina* of Fernando de Rojas (1499), the influence of a book in Castilian passed for the first time beyond the borders of Spain. Translated into various languages, *La Celestina* had an enormous vogue in Europe, and from that moment Spanish literature took on international proportions. The romances of chivalry represented by *Amadís, de Gaula;* the pastoral novel, represented by the *Diana* of Jorge de Montemayor; and the picaresque novel, represented by the anonymous *Lazarillo de Tormes* and by Mateo Aleman's *Guzman de Alfarache,* charmed Europeans and left perceptible traces in their literature; they were taken as exemplary expressions of heroism, of amorous illusion, and of the critical audacity of that demolisher of social values, the picaro.

**The Golden Age.** The most individual, and at the same time the most universal, values of Spanish literature attained their height of expression in the epoch between the opening of the sixteenth century and the middle of the seventeenth. This period began with the publication of *La Celestina* and ended with the work of Baltasar Gracián, that strange moralist much admired by La Rochefoucauld and Schopenhauer. Spain then reached its highest level of literary attainment and, through Cervantes and Lope de Vega, made of the novel and the drama literary types that deeply influenced subsequent developments outside of Spain. Three elements account for this extraordinary success of literary vitality: the tradition of the popular epic represented in the *romancero,* the learned tradition of Rome and of Renaissance Italy, and the tradition of Spanish life itself, which preserved, along with its Latin and Christian character, the influence of eight centuries of contact with Moors and Jews, an influence that has left its mark in the language, the proverbs, the poetic metaphors and songs, and also in certain mental and emotional habits of the Spanish people.

Many writers contributed their inventive, creative, and expressive capacity to the eminence of this period and it is undeniable that their originality was oriented and canalized by those unique mental and emotional habits to which allusion has already been made. In other countries the writer felt less prone to challenge or to criticize the society in which he lived, and the literature of England, France, and Italy about 1600 did not have as its primary theme the circumstances of contemporary life in these particular countries. The dramas of Shakespeare do not reflect directly the picture of English life in 1600; neither is the contemporary life of France spoken of in the dramas of Corneille and Racine. Outside of Spain the "literary epoch" and the actual epoch in which an author lived existed on different planes, at least in the most impressive forms of literary art. But in Spain the epoch of which the writer wrote and the epoch in which he lived have coincided on many eminent occasions. This contemporaneity had already been practiced in the *Poema del Cid* (1140), which never passes beyond the limits of its own time and in which the hero is at the same time poetic and historic; and in the greatest poetic work of the fourteenth century, the *Libro de buen Amor,* there are constant references to the life of Spain and to its cities, mountains, and rivers. An analogous phenomenon may be observed in the poetry of Juan de Mena and Jorge Manrique in the fifteenth century.

It is true that the literature of the sixteenth century some-

times continued the international orientation of Italian Humanism and did not mix poetry with the non-poetic life of the artist. The *Eglogas* of Garcilaso de la Vega thus refer to an abstract or generic world, and the same thing is true of the romances of chivalry of foreign origin, which are based on unreal history and geography. But this literary depersonalization did not produce the most perennial and universal values of the literature of Spain. We find these values almost always in works in which the plain spoken language and the Spanish land are intimately perceived and felt, and directly presented. So true is this that the plain fact that the characters in *La Celestina* seem to live in some late fifteenth-century Castilian city has given rise to an argument over whether the city is Toledo or Salamanca; similarly, *Lazarillo de Tormes* is inseparable from Toledo. It is not by chance, then, that the greatest work of this literature, the *Don Quixote* of Cervantes, is a most varied, complex, and effective vision of Spanish life at the end of the sixteenth century, represented equally in its smallest and in its greatest aspects. The same can be observed in the hundreds of plays composed by Lope de Vega, in which there is represented the fullness of Spain, its history from the Roman epoch to the days of the author; the manner of life of its peasants and kings, its cities, its intimate life, and thoughts; the sentiments, the clothing, the manners, and the grandeur as well as the miseries of the Spanish people. Tirso de Molina, Calderón, and other dramatists who continued to cultivate the dramatic genre invented by Lope de Vega also continued to reflect the concrete reality of the world in which they lived. This simple and evident fact enables us to see, on the one hand, the relation between literature and the form of life, and, on the other, permits us to understand how the literary genres developed by Spain and then transmitted to other literatures were possible.

The Spaniards are among the least objective of the European peoples, since only with difficulty can they separate what they do from what they feel and the circumstances which surround them. This fact is responsible for the lack of originality in Spanish philosophy and science, but it also accounts for the Spanish excellence in fiction. Even in the Middle Ages, the Spanish writer was already transforming the epic mythical personages that he had derived from foreign sources into historic, concrete, and present beings. The Cid of the *Poema* is a Castilian of the eleventh century set in the firm reality of his time, a reality familiar to those who heard the poem recited. The author, in fact, created the life of his personages in the image and likeness of his own life.

In this way, the generic personages of the traditional stories, or in general of any narrative, are converted into persons of flesh and bone. The readers of *La Celestina* saw in its main character a living person, and therefore any procuress is called a *celestina* in Spanish. Similarly, from the sixteenth century on, literary autobiographies are frequent, and a characteristic trait of the picaresque novel, initiated with *Lazarillo de Tormes,* is its autobiographical form, through the use of which the objectivity of narrative style is eliminated. The events are converted into the experiences of a life situated in the contemporary moment and in places which everyone knows. The same thing occurs in the religious literature. The medieval mystics speak of their divine emotions, and, through loving and desiring God, they aspire to be united with Him; but Teresa de Jesús wrote her autobiography in a very familiar style, related her most intimate experiences, and even included the sensations which she experienced in her body. Beneath the mystic, which is a generic type after all, there appears here the woman Teresa, born in Ávila, who travels in the cities of Castile as a concrete person, the contemporary of those who read her work in the sixteenth century; God and the spirit and body of Santa Teresa are here integrated in a manner that is particularly Spanish.

By virtue of this peculiarity of the Spanish character, the concept of the modern novel was appropriately developed in Spain with the *Don Quixote* of Cervantes. Before Cervantes, considerations of plot had largely determined the events occurring to, and the nature of, the characters of a story; in the *Quixote,* however, the events are generated by the protagonist himself as merely one aspect of the course followed by his life, and each of the authentic characters of the novel might be the nucleus for a possible autobiography.

Though in the novel the protagonist is shown influencing his own life and his own peculiar destiny, in the drama of Lope de Vega the characters exemplify rather the conflict between their spontaneous inclinations and what the ideals of Spanish society of the seventeenth century required of them. The Cid of Guillén de Castro's *Las Mocedades del Cid* ("The Youth of the Cid"), loves Jimena; but he must kill her father, who had insulted the Cid's father, because the idea of honor dominant in that society so required. Similarly, in *El Burlador de Sevilla* ("The Libertine of Seville") by Tirso de Molina, Don Juan challenges with his erotic passion the respect due to divine commandments and to social laws, and he is punished in spectacular fashion in order that his case may serve as an example. In such dramatic oppositions between passion and duty, the figure of the literary character becomes enormously more important; and it was because of such characters that the Spanish drama was diffused so successfully over Europe during the Baroque period of the seventeenth century, when the insecurity and the hesitation concerning the finalities of human life caused literature to shift its interest toward the problems of personal conscience. When such crises occurred, Europe more than once turned to the literature of Spain. Corneille thus found there the inspiration for the tragedy and the comedy inaugurated by him in France, and, in the same way, French fiction in the seventeenth century imitated or translated Spanish authors; in 1615 the French translator of the novels of Cervantes observed: "The Spanish possess something superior to us with regard to the order and the invention of stories."

Spanish personalism easily led also to the use of the autobiographical form, which, indeed, is inseparable from the Oriental tradition of the Peninsula. Antonio de Guevara speaks of himself in great detail in his *Epístolas,* and even the life of the Roman emperor Marcus Aurelius, a literary forgery of this period, is written in autobiographical form. Guevara was much read in France in Spanish and was translated into French, and the father of Michel de Montaigne enjoyed this reading a great deal. Furthermore, Montaigne's mother, Antonieta López, was of Spanish and Jewish origin, and it is therefore not strange that in such an atmosphere Montaigne should have conceived the autobiographical form of his famous *Essais,* a literary type which one would otherwise be surprised to find in the France of the sixteenth century. Another effect of the autobiographical urge in Spain that affected other European literatures is the analysis of one's own conscience, as practiced in the mystic works of Santa Teresa. This approach exerted a pronounced influence on the psychological literature of the seventeenth century.

**Decline and Rebirth.** Since the excellence of Spanish literature is particularly dependent upon subjective personal values and less upon objective political or economic vigor, it may happen that individuals of outstanding literary gifts will appear almost as often in epochs of national misery as in epochs of national security. It is true that the great period of

Spanish literature did occur at a time of great political power and economic prosperity, but this is by no means true of all important Spanish literary production. Thus, from the reign of Henry the Impotent (1454-1474) sprang the exquisite *Coplas* of Jorge Manrique, and between the seventeenth and eighteenth centuries, when Spain found herself almost isolated in Europe and when her culture had descended to the lowest level, there appears Feijoo, whose works are extraordinarily intelligent and surprisingly in tune with the science of his time. Somewhat later, at the end of the eighteenth century during the disastrous reign of Charles IV, we find a writer of the eminence of Melchor de Jovellanos and, to consider a related field, a genius of portrayal like Goya; after Ferdinand VII (1814-1833), when the country seemed but a shadow of itself and was torn by civil war, Spanish literature again reached a high level of excellence in the works of José de Larra, the Duke of Rivas, José de Espronceda, and other illustrious writers. So, in the dying Spain of the end of the nineteenth century, we have the extraordinary figure of Pérez Galdós. Finally, after the loss of the last Spanish colonies in 1898, everything pointed to a total eclipse of Spanish culture; but it is precisely during these last fifty years that there has occurred a literary rebirth, both artistic and scientific, rich in all kinds of values, and in contradiction to all the calculations and predictions of non-Spanish history. This phenomenon occurs in all fields of Spanish culture at this time. In literature Unamuno, Valle-Inclán, Azorín, Antonio Machado, and Baroja appear, among many others; in painting there are Sorolla, Zuloaga, and Picasso; in music, Albéniz and Falla; in science, Ramón y Cajal; in history and linguistics, Menéndez Pidal; and in philosophy, Ortega y Gasset and Zubiri. These men represent an aggregate of talent which would be sufficient to give dignity to any country; yet at the same time, twentieth-century Spain has suffered destructive political upheavals and bleeds with internal struggles. The case of Spain lacks analogy in the history of the modern world.

### THE LITERATURE OF SPANISH-AMERICA

Between 1810 and 1825, the Spanish empire in America, from Argentina and Chile north as far as Mexico, was fragmented into different republics. Cuba became independent in 1902. The language of these countries is Spanish, and in all of them the literature already initiated in the colonial epoch continued to be cultivated. Within this common tradition, the literature of Spanish-America offers regional peculiarities, just as in Spain a Galician element is perceived in Valle-Inclán and a Santanderian in Pereda. Similarly, the literary language of Spanish-America, is essentially the same as that of Spain in most instances, but in other cases, when local themes are involved, there appear certain peculiarities which vary as between Mexico and Argentina, Peru and Venezuela. The spoken language, moreover, as reflected in works of local inspiration, frequently contains both archaisms and native terms.

Spanish-American literature itself is very abundant and, at times, even excessive. Somewhat as in Spain, there is an irrepressible tendency toward diverting energy into literary channels. Thus, impulses which among other peoples have found expression in science, technology, industry, and many other kinds of social activities in Spanish-America have contributed rather to literary production. During a century of independent existence, this literature has shown a marked tendency to manifest the distinctive traits of each country. Argentina is distinguished by its preference for the theme of the gaucho, the countryman of the pampas, who has been idealized in multiple forms but has always been expressed in the language of rustics, as in the poem *Martín Fierro* of José Hernández and the novel *Don Segundo Sombra* of Ricardo Güiraldes. Similarly, the life of the Venezuelan countryside is found vividly described in the novel *Doña Bárbara* of Rómulo Gallegos. But together with this particularist tendency, there are also universal themes based on the feeling that Spanish America possesses a common meaning and destiny. Characteristic examples of this collective conscience are the works of the Ecuadorian Juan Montalvo, the Uruguayan José Enrique Rodó, and the Nicaraguan poet Rubén Darío, the last of whom the entire Hispanic world considers common property. Aside from these great figures, the most powerful personality is the Argentinean Domingo Faustino Sarmiento; among his abundant and sometimes hasty writings *Facundo* is outstanding, for here we can recognize the voice of a whole people that is conscious at the same time of its past, its present, and its future. In the highest moments of this literature, in Sarmiento, Darío, and Rodó, the common Hispanic notes of personalism, conflict between man and his destiny, and anxiety for eternity are clearly heard throughout the most varied and beautiful forms.

Spanish-American literature and thought, born in an epoch in which Spain found itself exhausted, were much influenced by the more vital nineteenth-century literature of France. French Romanticism and Naturalism thus inspired numerous Spanish-American novels and poems, and the positivist philosophy of Auguste Comte served as a gospel for the Spanish-American thinkers. During the twentieth century, however, and at the present time, an Hispanic reaction has occurred, and this has been accompanied both by the disappearance of many Gallicisms current in the language of the preceding century and by the renewed influence of Spanish thought, especially in Unamuno and Ortega y Gasset, and Spanish poetry. But there has also been a movement towards internationalism; the literatures of England, North America, Russia, and other countries are broadening the range of Spanish-American writers, and new problems characteristic of international thought have been discussed in the works of the Mexican Antonio Caso, the Argentinean Francisco Romero, and the Uruguayan Carlos Vaz Ferreira. A. C.

**SPANISH MUSIC.** The traditional music of Spain is characterized by regional variety, by strongly marked and often complex rhythms, and by certain exotic melodic and harmonic traits resulting from the divergent cultural and ethnic strains that have fused in the Iberian peninsula. The folk music of Andalusia, in the south, appears to have been influenced by such diverse factors as the ornamental style of the ancient Byzantine chant, the Arabian scales and melodies implanted during the Moslem occupation, the music of the gypsies who migrated to Spain from the fifteenth century onward, and the Hebrew synagogical chant. Out of these developed the type of Andalusian folk singing known as *cante jondo,* or "deep song," and its more modern derivative called *cante flamenco.* Other typical examples of regional folk music are the *seguidillas* of Castile, the *alalá* of Galicia, the *zortzico* of Biscay, the *sardana* of Catalonia, and the *jota* of Aragon. The *bolero,* another well-known dance, has many regional variants. Modern Spanish composers, as well as composers of many other nationalities, have drawn extensively on the rich store of Iberian folk music. Before dealing with the modern national movement, however, it will be advisable to survey briefly the historical development of Spanish music.

**The Middle Ages.** From 711 to 1492 a large part of

Spain was occupied by the Arabs and Moors, who overthrew the Christian Visigothic monarchy and implanted much of their culture in the Iberian peninsula from an early date. The treatise on music written by the Arab philosopher Farabi (870-950) did much to spread the influence of the Arab style of music throughout the peninsula. Later, Arabian or Moorish musicians were employed even at the courts of the Spanish kings, as that of Alfonso X of Castile and León (1221-1284), called "the Wise." This scholarly and music-loving monarch directed the compilation of the *Cantigas de Santa María,* a collection of over four hundred songs in praise of the Virgin Mary, which comprises one of the most notable musical monuments of the Middle Ages. The slightly earlier *Codex Calixtinus,* dating from the twelfth century, preserves the Latin hymns that were sung by pilgrims to the celebrated shrine of Santiago de Compostela. Also important both historically and musically are the pilgrim songs of another famous shrine, Montserrat, in Catalonia, dating from the fourteenth century and contained in the so-called *Llibre Vermell.*

**The Renaissance.** The important musical manifestations during the Renaissance were religious polyphony in choral music for the church, secular part-songs, solo songs, organ music, and music for the guitar or the lute. The secular part-songs are preserved chiefly in the *Cancionero de Palacio* ("The Palace Songbook"), a collection of nearly five hundred songs composed between approximately 1470 and 1525. The outstanding composer represented in this collection is Juan del Encina (1469-1529), poet, playwright, and musician, whose eclogues, or pastoral plays with singing and dancing, constitute the foundation of the lyric theatre in Spain. Music for the *vihuela,* a kind of lute, and solo songs with instrumental accompaniment are found in various music books printed during the sixteenth century, notably those of Luis Milán, Luis de Narváez, Alonso de Mudarra, and Miguel de Fuenllana. These composers were pioneers in developing the theme with variations as an instrumental form; often their variations were on Spanish folk tunes. Antonio de Cabezón (1510-1566) was the leading organist and composer for organ of this period, while Juan Bermudo, Bartolomeo Ramos de Pareja, and Francisco de Salinas wrote valuable treatises on music. Religious music reached its apex in the works of such composers as Cristóbal de Morales (c. 1500-1553), Francisco Guerrero (c. 1527-1599), and Tomás Luis de Victoria (c. 1548-1611), who is generally regarded as Spain's greatest composer. Because of the creative genius of these masters, the period in which they lived has since come to be known as the Golden Age of Spanish music.

**Baroque and Rococo.** Victoria's last work, the *Officium defunctorum* ("Office for the Dead") for six-part chorus, foreshadowed the more elaborate style of the Baroque period, which in Spain found its most characteristic musical expression in the religious music of Juan Bautista Comes (1568-1643), full of grandiose effects and violent contrasts. The Baroque period was marked by a shift of emphasis from the church to the theatre, however, and this led to the emergence of opera. The text of the first Spanish opera, *La Selva sin amor* (1629) ("The Forest Without Love"), was written by the famous dramatist Lope de Vega, but the composer of the music is unknown. The earliest Spanish opera for which the music has been preserved, at least in part, is *Celos aun del aire matan* ("Even Baseless Suspicions Kill"), with a libretto by the eminent dramatic poet Calderón de la Barca and a score by Juan Hidalgo, who also wrote music for several other plays by Calderón. In the eighteenth century the leading dramatic composers were José Nebra, who also wrote much religious music, Sebastián Durón, and Antonio Literes. Instrumental music is represented by the vivacious harpsichord sonatas of Antonio Soler (1729-1783), a pupil of Domenico Scarlatti. Soler also composed church music and some admirable quintets for strings and organ.

**The Nineteenth Century.** Spanish composers of the nineteenth century were largely concerned with developing a national opera. Many of them cultivated the *zarzuela,* a type of opera that was generally comic and contained spoken dialogue. Notable among these composers was Francisco Asenjo Barbieri (1823-1894), whose most famous *zarzuelas,* full of vivid local color, are *Pan y Toros* ("Bread and Bulls") and *El Barberillo de Lavapiés* ("The Little Barber of Lavapiés"). Other major composers were Joaquín Gaztambide y Garbayo, Rafael Hernando y Palomar, Cristóbal Oudrid y Segura, Emilio Arrieta y Corera, Fernández Cabellero, Federico Chueca, Ruperto Chapí, Tomás Bretón y Hernández, and Amadeo Vives. Felipe Pedrell (1841-1922) had more extensive plans and both collected the folk music of Spain and published the neglected masterpieces of the Golden Age. He was not entirely successful in his attempt to create a national lyric drama, but he became the leader of the next generation of composers, who achieved the modern renaissance of Spanish music.

**The Twentieth Century.** Pedrell preached the doctrine that each nation should build its art music on the foundation of its native folk songs and dances, and this doctrine led to the rise of a nationalist school of composers, among whom the most prominent were Isaac Albéniz (1860-1909), Enrique Granados (1867-1916), Joaquín Turina (1882-1949), and Manuel de Falla (1876-1946). Albéniz and Granados wrote mostly piano music; the former's masterpiece is the twelve-part suite *Iberia,* while the latter is remembered for his Spanish dances and the suite *Goyescas,* later made into an opera of the same title. Turina wrote colorful piano pieces as well as effective orchestral works such as *La Procesión del rocío.* Falla, considered the greatest of modern Spanish composers, achieved fame with an opera, *La Vida breve* (*Life Is Short*), the evocative tone-poem for piano and orchestra, *Noches en los jardines de España* (*Nights in the Gardens of Spain*), and the ballets *El Amor brujo* (*Love, the Magician*) and *El Sombrero de tres picos* (*The Three-Cornered Hat*). G. C.

**SPANISH SAHARA,** also called Rio de Oro, a region under Spanish control on the northwestern coast of Africa. Including the southern zone of Spanish Morocco (as the term sometimes does), Spanish Sahara is bounded on the north by French Morocco and on the east and south by Algeria and French West Africa, and is divided into three sections: the southern zone of the Spanish protectorate in Morocco, Saguiet el Hamra (Sekia el Hamra or Saguia el Hamra), and Rio de Oro. Often only the latter two zones are considered to comprise Spanish Sahara, or Rio de Oro, since the northernmost comes under the nominal jurisdiction of the Sherifian empire (French Morocco and Spanish Morocco). The northern section extends south from French Morocco to 27° 40′ N. lat.; Saguiet el Hamra lies between this meridian and Cabo Bojador at 26° N. lat.; and Rio de Oro, the name applied to the southern section as well as to the entire territory or the two southern sections, extends south from Saguiet el Hamra to 21° 20′ N. lat. and includes also the western half of Cap Blanc (Cabo Blanco) Peninsula south of that line. The combined area is about 109,200 sq. mi., and the population was estimated at 37,000 in 1950.

The terrain is low and desertic, with the Sahara coming down to the water's edge along this section of the Atlantic coast. Rainfall is negligible and irregular. There are no streams, merely wadis or dry runs. A few scattered oases and wells are to be encountered, but not enough to give rise to any significant agricultural activity. The sparse and tough vegetation of this desolate region supports some stunted cattle and a small number of camels, sheep, and asses, which constitute the principal resources of the nomadic tribes. These tribes represent a mixture of Arab, Berber, and Negro elements. Nominally they profess Islam, but their tenets and practices are hardly orthodox. Their social and economic organization is distinguished by a division into four castes which are clearly marked.

Towns are few and quite small. The chief ones are Cabo Yubi, Smara, and Villa Cisneros, the administrative centers respectively of the southern zone of the protectorate, Saguiet el Hamra, and Rio de Oro; and Puerto Cansado and La Aguera. All except Smara are on the coast. At Cabo Yubi and Villa Cisneros airports were constructed before World War II to serve air traffic on the route between Europe and South America. There are no ports of any importance, and only an infinitesimal amount of exports or imports.

In appearance, if not in actuality, the administration of Spanish Sahara is complicated by the fact that it is divided into three sections, one of which nominally forms part of the Sherifian empire of Morocco. For example, the khalifa, the sultan's deputy in the two Spanish-controlled zones of Morocco, has a majzen headed by a grand vizier, who in turn is represented at Cabo Yubi in the southern zone by a delegate and various lesser officials. In reality, the khalifa and his subordinates are responsible only to the Spanish high commissioner, who is in charge of governing all parts of Spanish Sahara. The actual administration is carried on by subordinate officials, whose principal seat is at Cabo Yubi. Order is maintained over the barren vastness of Spanish Sahara by a camel corps and a small air force.

Spain's interest in this section of the Sahara was first shown early in the sixteenth century when it was motivated by a desire to protect its newly acquired holdings in the Canary Islands, the inhabitants of which had already become accustomed to hunt slaves on the near-by mainland. But the original urge to colonize the area soon subsided and Spain allowed its claims to lie dormant until after the war with Morocco in 1859-1860. During the scramble for Africa in the 1880's, Spain obtained the submission of tribes over extensive areas in southern Morocco and on the Sahara coast. Villa Cisneros was established in 1885. However, France intervened, and by a series of agreements culminating in that of Nov. 27, 1912, Spain was obliged to reduce its claims substantially to within the present frontiers. Cabo Yubi was occupied in 1916 and La Aguera in 1920. *See also* Rio de Oro; Spanish Africa.

**SPANISH SUCCESSION, WAR OF THE** (1701-1714), the last of many conflicts resulting from the efforts of Louis XIV of France to increase his authority and influence in Europe. The immediate cause, which gave a name to the struggle, was the acceptance of the Spanish crown by Philip V, grandson of Louis, in February 1701. Arrayed against France and Spain were England, Holland, and Austria. The claimant of the Spanish crown supported by this coalition was Charles, second son of the Emperor Leopold I. Many other states, Portugal, Bavaria, Cologne, and Savoy among them, either were dragged into the war or entered for selfish reasons. Fear of France, however, was the compelling motive of those opposed to a Bourbon king of Spain. Their position was that of defense of the doctrine of the balance of power, which was held to be a guarantee of peace and an essential basis of international law. The only common people interested in the outcome were those of Spain. The Castilians supported Philip against the armies of invading foreigners. The Catalans supported Charles because Philip threatened to deprive them of their local liberties. In the later years of the war (1708-1713), when the armies of Louis were forced to defend France from invasion, the French began to support their monarch actively. For the rest of Europe, however, this was a war of rulers, using mercenary troops. It was conducted in accordance with the rules of the day which demanded economy and extreme caution. Other obstacles to a decisive action were lack of harmony among the allies, ignorance and lethargy of many of the commanders, and lack of steady support by the home governments. Students of military science find excellent material in the campaigns of Marlborough, Eugene, Villars, and Vendôme. On the whole, however, the war was a dreary succession of stalemates, disappointments, and reverses. Naval operations were little more impressive. Great Britain's navy kept the war alive in Spain on both the Portuguese and the Catalonian fronts. One Spanish treasure fleet was captured. Gibraltar and Minorca were taken and held by Great Britain. The more important campaigns on land were fought in Flanders, the Palatinate, the upper Danube, the Po valley, and in Spain. In April 1711, the Emperor Joseph I died, leaving his domains to Charles. Since a union of Spain and Austria was also a challenge to the doctrine of the balance of power, and even more dangerous to Bavaria, Savoy, and Cologne than the union of France and Spain, the opponents of Louis XIV commenced negotiations which led, in 1713, to the Peace of Utrecht. France and Austria continued the war for another year, finally settling their differences at the peace of Rastatt.

J. J. Van N.

**SPANISH TRAGEDY, THE** (c.1585), a blank-verse tragedy by Thomas Kyd, was one of the most influential and continuously popular plays of the Elizabethan theatre. Against the pseudo-historical background of a war between Spain and Portugal, it recounts the rivalry between Balthazar of Portugal and Horatio, son of Hieronimo, marshal of Spain, for the hand of Bel-Imperia, niece of the Spanish king. Through the ambitious scheming of Bel-Imperia's brother, Lorenzo, Horatio is murdered. The remainder of the action presents Hieronimo's pursuit of justice and revenge, culminating in his staging of a play in which suitable disposition is made of all the chief characters. Kyd's tragedy was a sensational success. Adapting many features of Senecan drama to the uses of theatrical spectacle, it established the basic principles and practices of Elizabethan tragic technique and was responsible for launching one of the most important Elizabethan dramatic genres, the tragedy of revenge.

H. R. W.

**SPARAXIS** [spəræ'ksɪs], commonly known as the wandflower, a genus of the iris family which has three species native to the Cape of Good Hope. The plant, from 1 to 2 ft. high, grows from a corm, or solid bulb, and has lance-shaped leaves 6 to 10 in. high, arranged in a basal rosette. The flower stems, of the same height, bear one, or occasionally more, 6-petalled, funnel-shaped flowers in a wide range of bright colors and markings. In California and in the South, sparaxis may be grown outside for spring blooming. In cold climates, wandflowers are grown under glass as pot plants.

**SPARKS, JARED** (1789-1866), historian, educator, and editor, was born in Willington, Conn., May 10, 1789. He graduated from Harvard in 1815, and while teaching there, 1817-1819, he also edited the *North American Review*. He went to Baltimore, where he served as pastor of a Unitarian Church from 1819 to 1823 and also as chaplain of the United States House of Representatives from 1821 to 1823. His principal interest, however, was in historical research and writing. He returned to Boston, where he became owner and editor of the *North American Review* from 1823 to 1831. He made it one of the most important periodicals in America, comparable with similar publications in Europe. As editor of the magazine, and in his later editing of the writings of noted men, Sparks revealed a serious editorial weakness, fear of offending the mighty.

He became interested in the American Revolution, for, as he once said, no complete history had yet been written of that important period. He never wrote his projected work, but he published *The Writings of George Washington,* 1834-1837, 12 volumes, *The Diplomatic Correspondence of the American Revolution,* 1829-1830, 12 volumes; *The Works of Benjamin Franklin,* 1836-1840, 10 volumes; and *Correspondence of the American Revolution, Being Letters of Eminent Men to George Washington,* 1853, 4 volumes. Between 1834 and 1838 Sparks edited 10 volumes of *The Library of American Biography* and a second series of 15 volumes between 1844 and 1847. Of the total of 60 biographies in these two series, Sparks wrote eight. Although he was not an accurate editor, amending and deleting passages in his source material, he opened large areas for historical research. His biographies of Washington and Franklin were widely read. Sparks was McLean Professor of History at Harvard from 1839 until 1849, when he became president of the university, serving in this capacity until 1853. He died at Cambridge, Mass., Mar. 14, 1866. M. K.

**SPARKS,** a city in western Nevada, an important railroad division point, situated in Washoe Co., 3 mi. east of Reno. The surrounding agricultural area is noted for its onions, potatoes, and hay, and gold and silver are natural resources of the area. The city has the mayor-council form of local government. Sparks was founded in 1905 by the Southern Pacific Railroad, which moved houses to the site from another locality where it had been carrying on construction. It was named after John Sparks, then governor of Nevada. The railroad shops maintained by the Southern Pacific Railroad are the chief industry. Pop. 1950, 8,203.

**SPARROW,** in the strict sense, any one of a large number of species of small songbirds combined in the genus *Passer* of the family Ploceidae or weaverbirds. Less exactly, the name sparrow is applied in the United States and Canada to a great variety of finches in the family Fringillidae, which properly should be known as buntings. The true sparrows are widely distributed in the temperate and tropical regions of Europe, Asia, and Africa. The best-known species, *P. domesticus,* the house or English sparrow, which originally ranged from the British Isles to Burma, was artificially introduced into the United States in 1850 in Brooklyn, N. Y. It was also released into Australia, New Zealand, Argentina, and the Hawaiian Islands and is now abundant in all of these countries. This bird is too well known to require a description; its relatives bear a close resemblance to it in pattern and often in coloration, although some of the tropical species wear yellow and chestnut in place of gray and brown, and some desert-dwelling forms are mainly sandy gray. Technically classed as singing birds, they have chattering and unmusical voices. Their nests are untidy structures built in holes and crevices, often under the eaves of occupied houses. H. G. De.

**SPARTA** [spɑ′rtə], the leading city of Laconia, the southeastern part of the Peloponnesos, and the purest Dorian of all the states of ancient Greece. Ancient Sparta was situated on the west bank of the Eurótas River and extended northward from the modern town of Sparta. The term "Lacedaemon," was applied to the Eurótas Valley, and the term "Lacedaemonians" was often used for the inhabitants of this area.

Sparta, which has a name that may mean "scattered," was composed of homes and estates scattered about an area centering on a low hill that has come to be called the Acropolis. It was originally an unwalled town; it remained so until after 200 B.C. The modern visitor is frequently disappointed by the scanty remains of the famous and once powerful state, but even when the power of Sparta was at its height, the traveler would not suspect from such buildings as he saw, that he was in a great city-state. The excavations by the British School at Athens, conducted from 1906 to 1910, have brought to light the remains of several buildings, notably the sanctuary of Artemis Orthia, the temple of Athena-of-the-Bronze-House, and the theatre. The theatre was of white marble, and according to Pausanias, who described the buildings of Sparta about A.D. 160, it was "worth seeing"; but this stone structure was of Roman date. From the low Acropolis a fine view is afforded of the Eurótas Valley, with its extensive olive orchards, and of the lofty range of Mt. Taygetus, steeply rising to the height of 8,000 ft. to form the western boundary of the Sparta domain.

Sparta was of comparatively late origin, having been established only after the "Dorian Invasion," the last wave of Greek people to enter Greece, which brought an end to the Bronze Age between 1150 and 1100 B.C. At first the newcomers may have lived at or near the sites of the towns that they had captured and often destroyed, but within a century the conquerors had established their "capital" by the Eurótas River, a few miles north of the strong pre-Dorian town of Amyclae, and almost two miles west of Therapnae, another Helladic or Mycenaean city.

Amyclae, the most important city in Laconia during the Bronze Age, wherein was found the "beehive" tomb from which the famed gold Vaphio cups were recovered, apparently did not fall immediately to the Dorian invaders but held out for possibly two or more centuries. Eventually, through a *synoikismos* ("housing together"), Amyclae was amalgamated with other regions to form the Sparta state.

Since Sparta was not in existence at the time of the traditional Trojan War (c. 1200 B.C.), the legend of the abduction of Helen by Paris from King Menelaus of Sparta must have been transferred to Sparta from some other site after Sparta had risen to prominence. At Therapnae, the site of an extensive Mycenaean or Bronze Age city before 1100 B.C., there was a sanctuary called the "Menelaion" where the cult of Menelaus and Helen was carried on down into Classical times.

An increase in population attended by related economic and social problems, led Sparta to adopt a policy of expansion. Aside from the colonization of Tarentum in Italy in the eighth century, Sparta restricted her political expansion to Greece proper. Messenia, to the west of Laconia, was conquered in the course of the First and Second Messenian Wars, variously dated between 725 and 600 B.C., and the Messenians were reduced to the status of Helots, or Spartan serfs. Indicative of the expansion of Sparta is the tradition that the Eleans were enabled, by the help of Sparta, to regain from their rival, Pisa, the control of the Olympic Games. The first recorded Spartan victory at Olympia was that of Acanthus in the long-distance race, about 720 B.C. For over a century the Spartan athletes were conspicuous for their victories at Olympia, winning in this period forty-six of the recorded eighty-one victories.

Aside from wresting some territory from Argos and from Arcadia, Sparta for the most part turned from conquest to the acquisition of power by treaties with various states. Sparta, as the head of the Peloponnesian League, actually dominated all of the Peloponnesos except Argos and Achaia, on the northern coast of the Peloponnesos, and by 550 B.C. had become the greatest military power in Greece. Thus there was an organized force to form a bulwark against the threatening Persian aggression, and the united efforts of the Peloponnesian League and of Athens and her allies brought about the decisive victories over the Persians at Salamis and Plataea in 480 and 479 B.C.

It was inevitable that the two great powers of Greece, Dorian Sparta and Ionian Athens, the land power and the naval empire, should come into conflict, and the Peloponnesian War broke out in 431. Eventually, in 404, Sparta, aided by such circumstances as the plague, blunders, and imperialistic over-expansion, brought an end to the Athenian empire. Sparta, however, proved to be a harsher master than Athens; discontent with Spartan hegemony led to more war, and Sparta lost her position as leader of Greece. Led by Epaminondas, the Thebans and their allies inflicted decisive defeats on the Spartans at Leuctra (371) and at Mantinea (362), and, except for spasmodic outbursts of force and occasional periods of power, Sparta declined thereafter and never recovered her former power and prestige.

Soon after 200 B.C., the "tyrant" Nabis built a wall around Sparta, and the theatre was built of stone. During the Roman period, beginning in 146 B.C., Sparta became a large and prosperous provincial city, and fortifications and other buildings were erected. Until about A.D. 350 Sparta flourished, though as a smaller and less consequential city than before. In A.D. 396 the city was destroyed by Alaric. The Spartan customs and "discipline" continued until the city's fall, and visitors came to watch the annual endurance contest, the flogging of the young Spartans, which continued to be held as of old at the sanctuary of Artemis Orthia by the Eurótas. Historically, Sparta was greatest from approximately 700 to 400 B.C.

Of considerable importance in world history is the influence exerted by the political and social system of Sparta. At the head of the Spartan state were two kings, one of the family Agidai, the other of the Eurypontidai. The origin of the dual kingship may be sought in a compromise effected after the two tribes had come to an impasse, each demanding that one of their clan should rule as king. The two kings sat with the Gerousia, "Council of Old Men," composed of twenty-eight men over sixty years of age, who were elected for life. The Apella was the popular assembly, to which were elegible all true Spartans who had attained the age of thirty and could maintain and equip themselves in the prescribed manner. Of later origin was the ephorate, a commission of five officials elected by the Apella, one from each of the five geographical divisions of Sparta. The five ephors, possibly as a consequence of Chilon's term of office (c. 555 B.C.), came to have powers greater than those of the two kings. To prevent insurrection on the part of the numerically superior Helots, a secret police force, the Krypteia, was continually active.

Strangely enough, the type of civilization now widely known as Spartan was not characteristic of early Sparta. British excavations have confirmed the theory, advanced by historians on literary grounds, that the civilization of Sparta before 600 B.C. was essentially on a plane with that of contemporary Athens and other Greek states. The remains of sculpture, the fine Laconian pottery, and the ivory, bronze, lead, and clay figurines found at the site bear witness to the quality of Spartan civilization, as do the poetry of Tyrtaeus and Alcman, of the seventh century. But soon after 600 B.C. an abrupt change took place. Art and poetry disappeared, and the names of Spartans ceased to figure among the names of victors at Olympia. Before the change was felt, about 600, the Spartan Gitiadas built the "Bronze House" of Athens; some fifty years later, in contrast, the foreign artists Theodorus of Samos and Bathycles of Magnesia were imported to build, respectively, the Skias at Sparta and the temple at Amyclae. Sparta was suddenly transformed into an armed camp, and the resulting military state henceforth produced only soldiers. The system that fostered this way of life is traditionally ascribed to Lycurgus, but whether Lycurgus was a god, a mythical figure, or an historical person, is undetermined. Even the time of his institution of Spartan discipline is not known, the date given to him ranging from the eighth century to the first half of the sixth century B.C. At any rate, this strict system was instituted, possibly between 590 and 580, not through fear of foreign aggression, but because of internal conditions.

The Spartan state was composed of three classes, the *Spartiatai* or true Spartans, the *perioikoi* ("dwellers-around"), made up of the inhabitants of federated towns that encircled the Spartan domain, and the Helots. Only the *Spartiatai* were privileged to vote and share in the government. They were forbidden to engage in trade, and the introduction of cumbersome iron money was designed to discourage their entry into business. Their landed estates, worked by Helots, were supposed to yield sufficient income to provide them with military equipment and to support their daily needs. The *perioikoi* carried on the necessary trade and industry of the country. They could not engage in the political life of Sparta, but they had certain rights, as well as the doubtful

privilege of serving in the army. With a vast number of Helots to carry on the daily work, the Spartan was able to devote his entire time to physical and military training.

It has been estimated that about 600 B.C. there were approximately 25,000 citizens, 100,000 *perioiḳoi,* and 250,000 Helots. Later on, the Spartans came to be outnumbered by the Helots fifteen to one. Wars and economic conditions reduced the number of *Spartiatai.* In the Persian Wars ( c. 480 B.C.) Sparta sent about 5,000 soldiers into the field, but a century later, in 371, only 2,000 Spartans fought in the Battle of Leuctra. In the third century it appears from a contemporary account that Sparta had only about 700 citizens.

It was, evidently, to maintain their position at the head of the State that the ruling Spartans felt it necessary to constitute themselves into a great standing army. The State came to control the life of the citizen from birth to death. The State decided whether the child at birth gave promise of becoming a healthy citizen or whether he should be exposed on Mt. Taygetus. The boy's first years at home were marked by privation and discomfort to toughen him for life. At the age of seven his training was taken over by the State, and his time was devoted almost exclusively to physical exercise and military drill. At the age of twenty the young Spartan joined a *syssition,* or "mess-group" of fifteen boys, and continued his military exercises and drill. He could marry, but only by stealth could he visit his wife. At the age of thirty he became a mature man and was privileged to attend the Apella, but his time was mostly spent at the gymnasia, clubs, and *syssition.* Thus the life of every Spartan was practically the same as that of every other, and war came as a welcome break in the monotonous military routine. The Spartan's gravestone bore only his name, unless he was killed in war, in which case the phrase "in war" was added to the inscription.

Spartan girls also underwent athletic training, engaging in running, jumping, wrestling, and the throwing of the discus and the javelin. Lycurgus is said to have instituted this training of girls in order that they might become strong and brave women, productive of a vigorous, healthy offspring.

The Spartans deliberately instituted their self-imposed despotism, a strict form of socialism, which robbed the individual of all freedom and initiative, and wiped out the beneficent influences of family life; yet the Spartan way of life appealed strongly to Plato, who incorporated many of its military, totalitarian, and communistic features in his ideal state. In modern times, Spartan discipline has often been taken as a model by totalitarian states in times of peace and war, and by some democracies in time of war. Thus, though Sparta long ago lost its political power, its political and cultural ideology, in some lands and at some times, continues to be of significance. J. P. H.

**SPARTA,** a city and summer resort in west central Wisconsin, the county seat of Monroe Co., situated on the La Crosse River, 26 mi. northeast of La Crosse. Founded about 1850, Sparta was made the county seat about 1855. The community has the mayor-council form of government. Sparta is the seat of a state school for dependent children, and 5 mi. from the city is located Camp McCoy, an army training camp. Sparta is an important market for the leaf tobacco raised in the vicinity and a shipping point for the region's berries, dairy products, and poultry. Transportation is furnished by the Chicago and North Western and the Chicago, Milwaukee, St. Paul and Pacific railroads. Local industries manufacture pumps, sewer equipment, brushes, and condensed milk. Pop. 1950, 5,893.

**SPARTACUS** [spa′rtəkəs], Thracian gladiator who organized a revolt of gladiators and slaves in Italy in 73 B.C., an uprising that was joined by runaways from the great estates in southern Italy. The insurgents took refuge on the slopes of Mount Vesuvius and at length became so numerous that they were able to defeat two Roman armies (72 B.C.). Spartacus was finally defeated and killed by Marcus Licinius Crassus in 71 B.C. The followers of Spartacus who escaped Crassus were intercepted and annihilated in northern Italy by Pompey, who was just returning from his victory over Sertorius in Spain. T. B. J.

**SPARTANBURG** [spɑ′rtənbɜrg], a city in northwestern South Carolina, the county seat of Spartanburg Co., located 80 mi. northwest of Columbia in the foothills of the Blue Ridge Mountains. Cotton and peaches are the chief crops of the surrounding region. In 1785 Thomas Williamson donated two acres of forest land to found the county. The county and the community which grew up subsequently derived their name from the Spartan Regiment, the popular name of the South Carolina militia, which distinguished itself in the Revolution. The battlefields of Cowpens and Kings Mountain, Revolutionary battles, are near by. The community's cotton industry dates back to 1816 when the first two cotton mills were established. Spartanburg was incorporated in 1831. During the Civil War its industries supplied arms and textiles to the Confederacy. After the Civil War the city's iron works diminished in importance, and the textile industry ascended to first place. In 1919 Camp Wadsworth, where the 27th, 6th, and 9th divisions were trained during World War I, was returned to the city, and part of it was designated as a memorial park. Spartanburg is the seat of Converse College for women and Wofford College for men. Near by is a state school for the deaf, dumb, and blind. Transportation is supplied by the Southern, the Charleston & Western Carolina, the Clinchfield, and the Piedmont and Northern railroads. Air service is maintained by the Delta and Eastern air lines. Spartanburg is one of the country's leading textile centers. In 1945 there were 42 cotton mills in the city and its immediate vicinity. In addition, there are flour and grist mills and railroad shops. The varied factory output also includes fertilizer, machinery, cottonseed products, lumber, and creosote. Pop. 1950, 36,795. A. W.

**SPARTEL** [spɑrtɛ′l], a cape forming the northwestern corner of Africa. It may be said to mark the point where the Strait of Gibraltar and the Atlantic Ocean meet. Known to the ancients as Ampelusium, Cape Spartel is 6 mi. west of Tangier in the International Zone of Morocco. The view from the promontory is spectacular and is an attraction to tourists. An international lighthouse, built in 1860, surmounts the cape. R. G. W.

**SPARTIVENTO, CAPE** [spɑ′rtivɛ′nto], known to the ancients as Promontorium Herculeum, a promontory 156 ft. above sea level marking the southernmost point in Calabria, and hence in continental Italy. It is surmounted by a lighthouse with a beam visible for some 30 mi. The waters around Cape Spartivento are noted for their roughness and shoals. R. G. W.

**SPATTERDOCK,** a common perennial herb, *Nuphar advena,* found in quiet streams or ponds, also known as yellow pond lily or cow lily. It ranges from Georgia to

Texas, Nebraska, Wisconsin, and New York. Large heart-shaped leaves, floating or erect, rise on spongy leaf stalks from the summit of the thick fleshy rootstocks. The yellow globular flowers, sometimes tinged with purple, are borne above the surface of the water and bloom all summer. The rootstocks of *N. advena* and seeds of the western species, *N. polysepalum,* have been used by the Indians as food. Spatterdock is also the common name of certain aquarium plants. One species of the latter, *N. japonicum,* is native to Japan and Asia. A. Gr.

**SPEAR.** *See* Arms and Armor (*Shafted Weapons*).

**SPEAR GRASS,** a perennial grass, *Stipa elegantissima,* native to Australia and often cultivated for its loose and feathery panicles of flowers. The grass grows as high as 3 ft. and thrives in sandy soils. It is closely allied to porcupine grass, *S. spartea.* J. C. Wis.

**SPEARMINT,** an aromatic perennial herb, *Mentha spicata,* of the mint family, closely allied to the peppermint. It yields an essential oil much used in flavoring. Spearmint is a native of Eurasia, grown since ancient times as a culinary herb, which has become widely naturalized on moist ground throughout North America. The smooth, erect, branching stems, 1 to 2 ft. high, bear narrow, sharply toothed leaves and purplish flowers in slender, interrupted spikes. R. P. T.

**SPECHT, FRANZ** [shpɛ′χt] (1888-1949), German linguist, was born at Rosslau in Anhalt on Nov. 1, 1888. He studied at the Universities of Leipzig and Berlin and in 1918 obtained his Ph.D. at Leipzig. In 1923 he became professor of Indo-European linguistics at the University of Halle, in 1937 at Breslau, in 1943 at Berlin, and in 1946 at the University of Mainz. He died on Nov. 13, 1949.

Specht's career began with his edition (1922-1924) of A. Baranowski's collection of Lithuanian dialect texts. His introduction to this work, which treated of Lithuanian grammar and contained a valuable historic linguistic commentary, laid the foundations of Lithuanian dialectology. In 1924 he contributed a collection of Latvian and Lithuanian fairy-tales, in German translation, to the series *Märchen der Weltliteratur.* Thereafter he began publishing, in the *Zeitschrift für vergleichende Sprachforschung,* a series of important treatises which shed light on Indo-European phonology and morphology, on prehistory as illustrated by linguistic data, and on the different layers of Indo-European development. These bear witness to Specht's wide range of exact and intimate knowledge of the history of all the important Indo-European languages.

Specht's major work on the origin of Indo-European declension (*Der Ursprung der indogermanischen Deklination,* 1944) is an attempt to elucidate the morphology of the language of the early Indo-European period by analyzing the word formation of the Indo-European languages. In its first part, on the Indo-European declension as a reflection of Indo-European civilization, Specht investigates the inflection of words that designated familiar objects and finds that these words in general had an irregular inflection, not that of the *o-* or *ā-* stems. In the second part, treating the origin and growth of Indo-European declension, he concludes that the word elements that follow the root of a word and are also found in the declensional cases were originally demonstrative pronouns, which came to be added to the root; these pronouns originally indicated place or direction in space. Specht's far-reaching conclusions are not accepted by all, but the wealth of his material and the excellence of his powers of interpretation and analysis make his work a stimulus and a source of information to scholars. **SPECTATOR, THE.** *See* Addison, Joseph; Essay.

**SPECTRA, STELLAR AND SOLAR.** Stellar spectra are the main key to the secrets of the stars and, as such, are of inestimable value to the knowledge of the universe. They are mainly of the dark-line type, only a small proportion of stars showing a bright-line spectrum. In accordance with the laws of spectroscopy, the spectral lines determine the elements of matter contained in the distant body, and also demonstrate motions of the bodies themselves.

**Stellar Spectra.** Stellar spectrograms are made in two ways: (1) A prism may be placed over the objective of a photographic refractor. This gives spectra of many stars on one negative and is used for purposes of classification. A special filter in front of the plate introduces particular spectral lines for orientation of the stellar spectra. (2) A spectroscope may be used at the eye-end of the telescope, with photo attachment. This has either prisms or a grating of parallel lines, and the slit of the instrument is at the focus of the telescope. A comparison spectrum from a laboratory source is thrown onto each side of the star's spectrum. This second method is of value for individual studies of stars.

Spectra from countless millions of stars can be classified in a small number of categories. There are seven main groups in the classification begun by Henry Draper at Harvard. They are named after the letters O, B, A, F, G, K, M. The last six include the greater proportion of all stars. The first six are the bluish stars; the *M*-stars are red. The classes *R, N,* and *S* have been added at the end, *R* and *N* being "side issues," and the *S*-stars a special class. It is notable that there is a continuous graded series of spectra, with transitions between groups. The special significance of the continuous feature is that difference in the spectral pattern is probably caused by difference in one physical feature in the stars, that is, temperature.

**Solar Spectrum.** The sun's spectrum is a band of beautiful colors from red to violet, crossed by thousands of dark (Fraunhofer) lines. Prominent lines have letters assigned them, such as the yellow *D*-line of sodium, with a wave length of 5893 Angstrom units. Fraunhofer lines mostly represent wave lengths "abstracted" from solar light by cooler gases around the sun. Certain lines in the sun's spectrum do not originate in the sun but in the earth's atmosphere.

**Planetary Spectra.** Spectrograms of planets are also valuable. Light from the sun enters a planet's atmosphere and is partly scattered and partly absorbed. The sunlight penetrates more or less, depending upon the particular planet's atmosphere. In any case, analysis of the light assists in finding clues to the nature of the planet's atmosphere. For instance, water vapor and free oxygen are not found in quantities large enough in Venus' atmosphere to register in the spectrum, although bands of carbon dioxide are present in surprising amounts. Jupiter's spectrum shows heavy concentrations of ammonia and methane.

**Other Spectra.** Spectra of comets are occasionally made, and these show faint solar lines as well as bright bands produced by fluorescence of the cometary gases. Such gases may be cyanogen, carbon, nitrogen hydride, and other compounds. Spectra also are made of variable stars, novae, planetary and diffuse nebulae, and far-distant galaxies. All spectra reveal facts otherwise unobtainable. *See also* Astronomical Instruments; Spectroscopy; Stars. H. S. R.

**SPECTRE DE LA ROSE, LE** [lə spɛ′ktr də la rɔ′z], a ballet by Michel Fokine, based on a poem by Gautier, set to Weber's *Invitation to the Waltz,* and first performed at Monte Carlo in 1911. A young girl returns from a ball. She falls asleep and dreams that her rosè comes to life and dances with her. She awakens and sadly embraces the wilting rose. Just as the last few bars of *Invitation to the Waltz,* although essential to the composer's purpose, are likely to seem anticlimactic, the brief passage of the young girl's awakening in the ballet appears ineffective after the applause following the exit of the Spectre. Vaslav Nijinsky and Tamara Karsavina constituted the original cast. The sensational leaps of Nijinsky upon his entrance and his exit gave the ballet a degree of fame it might otherwise never have attained. *See also* BALLET. F. G. P.

**SPECTROGRAPH.** *See* ASTRONOMICAL INSTRUMENTS (*Astrophotography*); SPECTROSCOPY.

**SPECTROHELIOGRAPH.** *See* ASTRONOMICAL INSTRUMENTS (*Astrophotography*).

**SPECTROPHOTOMETRY.** *See* ANALYTICAL CHEMISTRY (*Physical Methods*).

**SPECTROSCOPIC BINARIES** [spɛ′ktroskɒ′pɪk bai′nəriz], double stars that revolve around a common center of gravity and have components apparently so close together that they cannot be separated with the largest telescopes. The fact of their being binary systems is known from spectroscopic observations, that is, by the shift in their spectral lines due to motion. This change of position of spectral lines determines the period of revolution of the stars. Capella, $\beta$ Aurigae, Mizar, and Spica are typical spectroscopic binaries. *See also* BINARY STARS. H. S. R.

**SPECTROSCOPY** [spɛktrɒ′skopi], the observation and interpretation of the light emitted by physical objects; more especially, the interpretation of the light emitted by excited atoms (and molecules) in the gaseous state.

Lower case letters are used for the quantum numbers of an electron, *n, s, l, j, m,* and capital letters for the atom as a whole, *N, S, L, J, M.*

## EARLY HISTORY

**Origin of Science.** The science of spectroscopy had its beginning in the observation by Sir Isaac Newton in 1666 that the white light from the sun was dispersed into a colored spectrum by passage through a glass prism. In Germany in 1814, J. Fraunhofer extended Newton's discovery by observing that the sun's spectrum, when sufficiently dispersed, was crossed by a large number of fine dark lines, later known as Fraunhofer lines. Terrestrial sources, such as flames, were found to emit bright lines which were characteristic of the chemical elements in the flame. Foucault, the French physicist, observed in 1848 that a flame containing sodium would absorb the yellow light emitted by a strong arc placed behind it. These facts were brought together in 1859 by G. Kirchhoff in his famous law: that the ratio between the powers of emission and the powers of absorption for rays of the same wavelength is constant for all bodies at the same temperature. He explained that the Fraunhofer lines in the sun's spectrum were caused by action of elements in the cooler sun's atmosphere in absorbing the continuous spectrum emitted by the hot interior of the sun. Analysis of the sun's atmosphere thus became possible. The method was extended later to stellar spectra and constitutes our only means of studying the chemical elements occurring in the stars.

**Spectra Measurement.** The provision of accurate wave length measurements resulted from the work of Rowland, Michelson, Fabry, and Perot. The relative accuracy attained reached one part in ten million, and most measurements can be relied on to .01 Å, where the Angstrom unit (Å) is $10^{-8}$ cm. The visible spectrum extends between the approximate limits 4000 Å and 7500 Å, but observations by photography have been made from about 10 Å to 13000 Å. Spectra can be produced in a great variety of ways. The commonest is to use the element whose spectrum is required as the poles of an electric arc, or in carbons which form the poles. Sparks of any intensity may be employed for higher excitation. For special purposes, other sources are available, such as low pressure gas discharges, vacuum ovens, fluorescence produced by radiation, absorption, and atomic beams. Complete observation of a spectrum may involve the use of several different sources, because different parts of the spectrum may be differentially excited. It also may require a variety of instruments, in order to cover the complete range of intensities and wave lengths.

**Formula for Lines.** Regularities among the lines in the simpler spectra were found in the early work. The most

*Fig. 1—SPECTROGRAPH OF BALMER SERIES OF HYDROGEN*

obvious was the regular progression of lines, known as the Balmer Series of Hydrogen (*See* Fig. 1). Attempts to fit these lines into a system of harmonics from analogy with mechanical vibrations were unsuccessful, but, in 1885, J. J. Balmer discovered that the lines were given by a simple formula, which in recent notation is:

$$\nu = R\left(\frac{1}{4} - \frac{1}{n^2}\right).$$

In this formula, $\nu$ is the wave number, or reciprocal of the vacuum wave length, $R$ is a constant, and $n = 3, 4, 5,$ etc., for the successive lines. It was soon found that there were series of lines in other spectra which satisfied a somewhat modified formula, due to Rydberg. This, using the same constant $R$, is:

$$\nu = \nu_\infty - \frac{R}{(n + \mu)^2}.$$

In this formula, $\nu_\infty$, $R$ and $\mu$ are constants and it is obvious that $\nu_\infty$ is the limit of the series, i.e., that point in the spectrum to which the lines converge. The alkali metals, for example, produced the following series: the principal series, containing the strongest lines; the sharp and diffuse series, so called because their lines were sharp and diffuse, respectively; and the fundamental or Bergmann series in the infrared. All of these obey such formulae. In addition, the Rydberg-Schuster law was discovered, giving certain relations connecting the various series.

The most striking fact emerging from these observations was that the wave number of a spectrum line always appeared as the difference between two other numbers. This was stated in the Ritz combination principle and became fundamental in the quantum theory.

## BOHR THEORY

**Quantum Picture.** In 1913, N. Bohr initiated a new era in the interpretation of spectra when he gave the first quan-

tum picture of the hydrogen atom. Following E. Rutherford's suggestion of a planetary atom, Bohr applied the principles of the quantum theory to the system consisting of a positively charged nucleus, containing the main atomic mass, and an electron revolving around it in the inverse square force field. He made the radical assumptions that the angular momentum in an allowed orbit had to be an integer times the quantity $h/2\pi$, where $h$ is Planck's constant, and that the radiation obeyed the equation $h\tilde{\nu}=W_1-W_2$, in which $\tilde{\nu}$ is the frequency, and $W_1$ and $W_2$ are the energies of the atom in any two states. The latter relation was obviously inspired by the Ritz combination principle. When put in terms of known atomic constants, the Bohr relation gave:

$$\nu = N^2R\left(\frac{1}{n^2}-\frac{1}{m^2}\right),$$

where $n$ and $m$ are integral and $m$ is larger than $n$, and where $\nu$ is the wave number of a line, $N$ is the charge on the nucleus in electronic units, and

$$R=\frac{2\pi^2\mu e^4}{ch^3},$$

$c$ being the velocity of light and $e$ and $\mu$ the charge and mass of the electron. The agreement with observation is well within the experimental error. The spectrum of hydrogen is now known to include the series for which $n=1$ (Lyman series), $n=2$ (Balmer series), $n=3$ (Paschen series), $n=4$ (Brackett series), and $n=5$ (Pfund series).

The general picture of an atom as a positive nucleus surrounded by a cloud of electrons emerged from the Bohr theory and became fundamental in all atomic theory. This meant that the whole structure could exist in a large number of discrete energy states, and radiation took place according to Bohr's frequency condition. The condition of zero energy employed by Bohr is that in which the nucleus and one electron are infinitely separated, i.e., the atom is ionized. In terms of the series formula, this means that the limit corresponds to ionization. Beyond the series limit, a continuum exists which corresponds to the removal of the electron with a finite velocity. Such a final state is not quantized and can theoretically yield the observed continuous spectrum, which extends from the series limit toward shorter wave lengths.

## EXTENSION OF BOHR THEORY

**Heavier Atoms.** In the years immediately following Bohr's theoretical discovery, the application of its principles to the spectra of heavier atoms was taken up by A. Sommerfeld and many others. An important advance was made by considering the possibility of elliptical as well as circular orbits. Because of relativity effects, this introduced small energy differences, which could account for fine structure in the hydrogen lines, but its importance increased greatly when it was made the basis for explaining the important differences between hydrogen and other spectra.

*Sodium Series.* It was pointed out that sodium gave a number of series which obeyed the Rydberg formula:

$$\nu=\nu_\infty-\frac{R}{(n+\mu)^2}\quad .$$

These series are related in such a way that they can all be described by means of the following diagram (*See* Fig. 2), usually called a Grotrian diagram.

In the diagram, the value of $\nu_\infty$ for the principal series is plotted on the left, downward from the zero line, while the variable term values for that series are plotted in the second column. The first column is then filled by the variable terms of the sharp series and a third column is used for the variable term of the diffuse series. A fourth column includes the variable term of the fundamental series. These columns are labelled $^2S$, $^2P$, $^2D$, $^2F$, and the levels in each column are

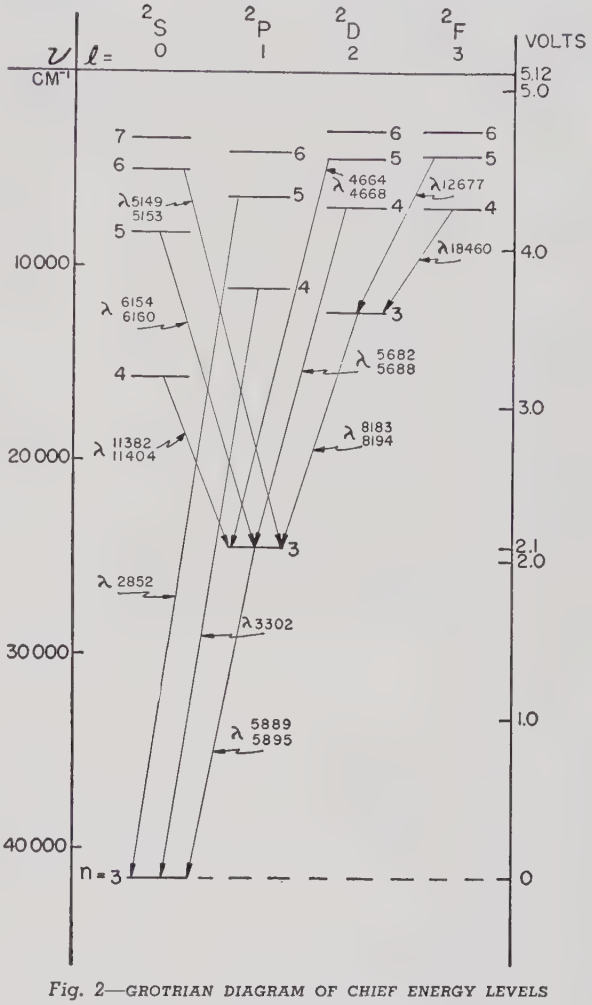

*Fig. 2—GROTRIAN DIAGRAM OF CHIEF ENERGY LEVELS OF SODIUM*

given a running number. Obviously, from the construction of the diagram, the wave number of a spectrum line is given by the vertical difference between the corresponding levels in the diagram and the various series can be written formally as follows:

| | |
|---|---|
| Principal series | $3^2S-n^2P$ |
| Sharp series | $3^2P-n^2S$ |
| Diffuse series | $3^2P-n^2D$ |
| Fundamental series | $3^2D-n^2F$ |

The significance of the superscript 2 is explained later; $n$ is called the principal quantum number of the level of higher energy.

It might appear from the Ritz principle that an observed frequency should be obtained by taking the vertical difference between any two levels. All such differences, however, do not correspond to radiation. It is found empirically that only transitions between levels in neighboring columns give lines of appreciable intensity. In agreement with theory, this restriction is formally introduced by assigning to each column a number $l=0$, 1, 2, etc., for $S$, $P$, $D$, etc., and the rule is then $\Delta l=\pm 1$ for radiation.

*Doublet Spectra.* An additional refinement of the greatest importance was found early in spectra such as sodium. Each line was found to be at least double, the lines of the principle series closing together in successive terms, and the diffuse and sharp series having constant differences. This fact necessitated the doubling of certain of the terms. The spectra showed that the $S$ terms were always single, the $P$ terms double and decreasing in separation up the series, the $D$ terms double but much narrower. Still another selection law was found to be necessary, since all possible transitions between doublet levels did not occur. This required the introduction of another quantum number called $J$ and having the values: for $S$ terms ½; for $P$ terms ½ and 1½; for $D$ terms 1½ and 2½; and so on. The rule which gives all observed transitions is $\Delta j = 0$ or $\pm 1$. Accordingly, a $^2P - {}^2D$ group includes only three lines since $^2P_{1/2} - {}^2D_{2}{}^{1/2}$ is not an allowed transition under this rule.

*Alkali Metals.* Many atoms emit spectra of the same character as sodium, notably all of the alkali metals. The metals *B, Al,* etc., have doublet spectra lacking the lowest $^2S$ term, and both they and copper, silver, and gold have additional complications. Doublet separations increase rapidly with increasing atomic weight, so that the name "fine structure," usually applied to this feature of spectra, is somewhat of a misnomer. For instance, in lithium $\Delta\nu(^2P) = .34\text{cm.}^{-1}$ and in cesium $\Delta\, \nu = 554.0$. It was also found quite early that numerous spectra exist which have two separate systems of series: one of single levels, and one of triple levels. They are emitted by atoms which follow the doublet-emitting atoms in the periodic table.

*Penetrating Orbits.* The general explanation of these facts is as follows. An electron orbit of high eccentricity approaches the nucleus closely. Such an orbit in an atom of many electrons penetrates into the inner electronic structure and comes under the influence of the higher field existing there. It is, therefore, more tightly bound than a nonpenetrating electron and is lower in the energy scale. The letter $l$, introduced above, corresponds in the quantum mechanics to the angular momentum. Theoretically $S$ terms are due to penetrating orbits and lie lower than $P$ or $D$ orbits of the same total quantum number. $F$ terms correspond to nearly circular orbits and have energies very close to the hydrogen values, as would be expected. The quantum mechanics gives the rule for a transition $\Delta\, l = \pm 1$ in agreement with observation.

*Electron Spin.* The doublet character of the terms, which was at first thought to be due to a characteristic of the nucleus, led Goudsmit and Uhlenbeck in 1925 to the introduction of the idea that the electron must possess an intrinsic spin of angular momentum $\frac{1}{2}\frac{h}{2\pi}$ and a magnetic moment $2\frac{e}{2mc}\frac{1}{2}\frac{h}{2\pi}$. In the quantum theory, the total angular momentum of the electron, and, in the cases under consideration, the whole atom, can accordingly have only the two values $j = l + ½$ and $j = l - ½$, which differ in energy by a calculable amount.

## ZEEMAN EFFECT

**Split Lines.** In 1896, P. Zeeman discovered that, when a source of spectrum lines is placed in a strong magnetic field, the lines are split up into a number of close components whose displacements from the original position of the line are proportional to the field. This is what would be expected classically of a Bohr atom in a magnetic field. The magnitude of the observed splittings and the number of components do not, however, agree with the classical result. When a charge is moving in an orbit of angular momentum $P$, the magnetic moment associated with its motion is $\frac{e}{2\mu c} \times \text{P}$. To account for the anomalous Zeeman effect, the angular momentum of an electron is taken as $\frac{1}{2}\frac{h}{2\pi}$ and the magnetic moment as:

$$\mathbf{2}\,\frac{e}{2\mu c}\,\frac{1}{2}\,\frac{h}{2\pi},$$

or twice as great as might be expected. When an atom is introduced into a magnetic field, a precession around the field direction results, and the component of the magnetic moment in the field direction retains a constant value $M$ which, in the quantum theory, can only be one of the following integral values: $M = J$, $(J - 1)$, and so on to—$(J)$. The energy of each of these precessional motions differs from that of its neighbors by a constant amount, so that the effect of the field is to split a level $T_0$ into several equally spaced levels given by $T = T_0 - M\, g\, L$, in which $L$ is the classical splitting predicted by Lorentz and $g$ is the factor by which the atom departs from the classical case because of the anomalous electron moment. The value of $g$ is:

$$g = 1 + \frac{J(J+1) + S(S+1) - L(L+1)}{2J(J+1)}$$

**Combined Levels.** When two levels combine to give radiation in the presence of a magnetic field, transitions occur only for $\Delta\, M = 0, \pm 1$, the zero changes giving light polarized with the electric vector in the direction of the field, and the $\pm$ changes, perpendicular to the field. Since the $g$-values vary for different states of the atom, the Zeeman effect affords a powerful means of telling the nature of the two levels which give rise to an observed line. A measurement of all the components gives not only the two $J$-values involved, but also the two $g$-values associated with them, and, consequently, the term types. A further effect occurs (Paschen-Back effect) if the field is increased to such an extent that $M\, g\, L$ becomes larger than the fine structure, due to the interaction between the electron spin and the electron orbit. The Zeeman pattern becomes unsymmetrical, and, eventually, goes over into a simple classical pattern about the center of gravity of the fine structure. In this condition, the $J$-value of the atom no longer exists because the powerful magnetic field has effectively broken down the coupling between $L$ and $S$. The atom still has an $M$ value, but this is the sum of $M_L$ and $M_S$. These two new quantum numbers are the components of the spin and orbital momenta in the direction of the magnetic field.

## COMPLEX SPECTRA

**Singlets and Triplets.** It has been mentioned above that, from an early date, spectra were known which required the assumption of a set of single levels and a set of triple levels. Numbers had to be assigned to all of these levels to account for the emitted lines. Those numbers, now known as $J$-values, are, 0, 1, 2, etc., for $^1S$, $^1P$, $^1D$, etc., for $^3S$, $J = 1$; for $^3P$, $J = 0$, 1, 2; for $^3D$, $J = 1$, 2, 3, etc. The rule for a radiative transition is $\Delta J = 0, \pm 1$, with the exception that $J = 0$ to $J = J = 0$ does not occur. In the spectra of light atoms, there are few and faint lines due to transitions from one system to the other, but, from heavy atoms, such intersystem lines may be very strong. For example, $\lambda$ 2536, one of the strongest lines in the mercury spectrum is $^1S_0 - {}^3P_1$.

Generally, though not always, it is true that the triplet levels are lower than the corresponding singlet levels, and that the lowest level of all is a $^1S$, for which there is no triplet counterpart. The Zeeman effect of singlets and triplets is deducible from the same formula, which applies to doublets if we take $S = 0$ for singlets and $S = 1$ for triplets.

**Multiplets.** In 1922, Catalan made the important discovery that there were groups of lines in the spectrum of manganese that were more complicated than triplets. He showed that such "multiplets" could be formally explained by assuming that the combining terms had more than three components. It became necessary, therefore, to extend the possible term systems to include quartets, quintets, etc. The key to the existence of multiplicities, other than the doublets of one electron spectra, was found by Russell and Saunders in 1925. From very complete analyses of the spectra of the alkaline earths, Russell and Saunders were led directly to the necessity of believing that the atom radiates as a whole, and that more than one electron may change its state during a transition. The state of the atom is then the resultant of the states of several electrons, presumably two in the case of calcium. Accordingly, they assumed that the resultant $L$ of the atom was the vector sum of the $l$'s of the electrons, and that, likewise, the resultant $S$ was the sum of the electron spins. For two electrons this leads at once to $S = \frac{1}{2} + \frac{1}{2} = 1$ or $\frac{1}{2} - \frac{1}{2} = 0$, giving the proper values for triplets and singlets. The type of term is determined by the quantum number $L$, which can have any positive value from $|l_1 = l_2|$ to $|l_1 - l_2|$. For instance, if we use $s$, $p$, $d$ to denote electrons with $l = 0$, 1, 2, respectively, the structure $sd$ gives $^3D$ and $^1D$ terms. Likewise, the structure $pd$ gives $^3P$, $^3D$, $^3F$, $^1P$, $^1D$ and $^1F$, and an electron transition from $p$ to $s$ is the origin of several multiplets instead of one, as in a doublet spectrum. These three multiplets in calcium are shown in Fig. 3.

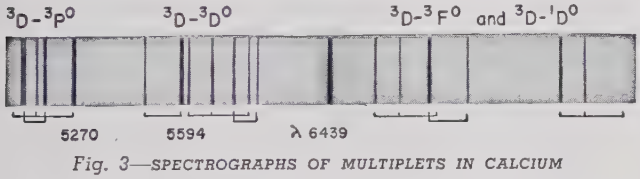

*Fig. 3—SPECTROGRAPHS OF MULTIPLETS IN CALCIUM*

*Change in Rule.* The former selection rule must be altered to take account of the new facts. Its most general form is that the arithmetical sum of the $l$'s must change from odd to even, or vice versa, in a radiative transition. Usually, however, the stricter rule holds, meaning that one $l$ changes by unity and the others remain fixed. The $J$ values of the various terms are given by the vector sums of $S$ and $L$, so that the number of levels in a term is $2S + 1$ or $2L + 1$, whichever is the smaller. Accordingly, $S$-terms are always single, $P$-terms never more than triple, and $D$-terms never more than quintuple, no matter how great the multiplicity.

The Russell-Saunders coupling scheme allows an explanation of the observed occurrence of even multiplicities with an odd number of electrons, and vice versa. Because the electron spin is half integral, the resultant spin for an odd number of electrons is also half integral, and the multiplicity $2S + 1$ must be an even integer. If the number of electrons is even, $2S + 1$ is an odd integer. Three electrons can then give rise to quartets and doublets, four electrons to quintets, triplets, and singlets, and so on. Such multiplicities are observed in the spectra of the first long period, of elements in the periodic table rising to octets, sextets, quartets, and doublets in manganese.

To describe an energy level of an atom, procedure requires that its $S$, $L$ and $J$ values be stated. It is customary to use a capital letter for the $L$ value, with a left superscript giving the multiplicity $2S + 1$, and a right subscript giving the $J$-value. The letters adopted for levels of successively higher $L$ starting from $L = 0$ are $S$, $P$, $D$, $F$, $G$, $H$, $I$, $K$, $L$, $M$, $N$, $O$, $Q$. For example, if a level has $S = 2$, $L = 4$ and $J = 3$, it is written $^5G_3$.

**Atomic Model.** Certain general features of spectra are explainable qualitatively, and, to a certain extent, quantitatively, by the Bohr theory and the more correct wave mechanics. There are various energy differences which can be visualized as follows. The electron, with its spin and magnetic moment, moves in an orbit around the charged nucleus in both an electric and magnetic field. The potential energy of the electron in the magnetic field depends upon the orientation of the electron spin; therefore the levels $J = l + \frac{1}{2}$ and $- \frac{1}{2}$ have different energies, the lower being $j = l - \frac{1}{2}$ in agreement with observation. In the more complicated case, where the atom has a spin vector $S$, this same magnetic interaction produces a splitting into a number of levels. There is an energy term which is proportional to the cosine of the angle between $L$ and $S$, and this leads, in quantum mechanics, to the Lande interval rule. This rule, found to be approximately true in practice, is that the energy intervals between the levels of different $J$ are in proportion to the greater of the two $J$'s surrounding them. For instance, a $^3P$ term with $J$'s 2, 1, 0 should have intervals in the ratio of 2:1.

**Energy Difference.** Another separation which was important in the theoretical development is that between singlets and triplets. In a spectrum like calcium, $^3P$ is usually found below $^1P$ of the same principal quantum number $n$. This was based on a crude atomic model and was viewed as due to the forces between the two electron spins, the energy difference being a measure of the work necessary to reverse one spin with respect to the other. However, this naïve explantation was insufficient, and Heisenberg showed that the energy difference is due to exchange forces, which enter in quantum mechanics because of the identity of the two electrons. Another energy difference is that introduced by the different angles between $l_1$ and $l_2$ when they are coupled together to give different resultant $L$'s. Simple theory predicts that such terms should have energies in the order of their $L$ values, with largest $L$ lowest, but this is by no means the case in observed spectra.

**Intensities of Lines.** The relative intensity of spectrum lines covers a very wide range. It depends on the types of terms involved and on the $J$-values. Detailed formulae have been deduced for certain types of transition, especially for Russell-Saunders coupling. Agreement with observation is only approximate but is usually sufficiently close to assist in the identification of most terms of a spectrum. In general, strong lines arise from changes of $J$ in the same direction as $L$ and the strongest involve the largest $J$'s.

## SPARK SPECTRA

**Analysis and Rules.** As remarked above, the arc spectra of elements of even atomic number have odd multiplicities and vice versa. If, however, the means of excitation of the spectrum is more vigorous, for example a condensed spark, a new spectrum appears for any particular element consisting of terms of the opposite parity. The first spark spectrum of calcium is a doublet spectrum similar in every way to the

ordinary spectrum of potassium, except that in the series formulae $4R$ must be used in place of $R$. Such a spectrum is interpreted as being due to the calcium atom, from which one electron has been removed, leaving it with a single outer electron like potassium. Obviously, this idea can be extended to the spectra of atoms with more and more electrons removed. The spectra so obtained alternate between odd and even multiplicities and resemble the arc spectra of atoms of lower and lower atomic number. Such isoelectronic spectra are usually designated as *K*I, *Ca*II, *Sc*III, etc. As a special case, all of the spectra *H*I, *He*II, *Li*III, etc., are hydrogen-like, and their term values can be calculated accurately from the wave mechanics. The term values increase as the square of the nuclear charge, or atomic number, and the spectra, therefore, recede toward shorter and shorter wavelengths, where they form a useful set of standard wavelengths in the far ultraviolet. Simple rules exist in more complicated cases, allowing a step by step analysis to very high ionizations. The highest ionization recorded in the literature in 1947 was *Cu* XIX.

## PAULI EXCLUSION PRINCIPLE

**Periodic System.** The spectra of the elements should be expected, as they do, to reveal the reasons for the periodic character of the system of elements. At the beginning of each short period in the Periodic Table, there is an element with an ordinary doublet spectrum whose lowest term is a $^2S$. This is followed in each case by an element having a triplet-singlet spectrum with $^1S$ lowest. The following element has a $^2P$ as its lowest term, and is succeeded by an element with $^3P$ lowest. From this and much other evidence, Bohr in 1922 was able to give a logical picture of the building of the periodic system. It appeared necessary to assume that only two electrons with $n=1$ are built in, followed by two with $n=2$ and $l=0$, to give beryllium $1s^2\ 2s^2$ (using an obvious extension of the notation used above). In the following six elements, electrons with $n=2$ and $l=1$ are built in to give $1s^2 2s^2 2p^6$ for neon. The repetition of this process for $n=3$ leads to $1s^2 2s^2 2p^6 3s^2 3p^6$ at argon. Obviously, there is some fundamental law of nature preventing an atom from acquiring more than two *s*-electrons, or more than six *p*-electrons, of the same principal quantum number $n$. An examination of the remainder of the periodic system extends this law to the limitation of *d*-electrons to ten and *f*-electrons to 14. That law, whatever its origin, creates the periodic system.

**Single Rule Stated.** In 1925, W. Pauli stated a principle bringing the periodic properties of the atomic system under a single rule. This provides that no two electrons in an atom may possess exactly the same quantum numbers. The law yields the result that the number of electrons of the same $n$ and $l$ may not exceed $2(2l+1)$, in agreement with the known facts. The short periods are produced by the building in of *p*-electrons and the long periods by the *d*-electrons. The rare-earth group appears when the *f*-electrons are built in. The application of the Pauli principle also reduces the number of terms to which any electron configuration can give rise. In particular, a complete group of electrons always gives a $^1S_0$ term, which has both spin and angular momentum zero. Moreover, the removal of any number of electrons from a closed group gives the same resultant as the presence of that same number. Consequently, there is a symmetry of the periods about the center, at which an *S* term always appears: a $^4S$ in the short periods, a $^6S$ in the long periods, and an $^8S$ in the rare-earth period. The terms produced by electron groups which are more than half filled are inverted, i.e., the level of greatest $J$ is lowest in energy.

## SPECTRUM ANALYSIS

**Division of Terms.** In doublet spectra, one can divide the terms into two groups which do not combine within themselves to give radiation. These are $^2S$, $^2D$, $^2G$, etc., and $^2P$, $^2F$, and $^2H$, etc., having even and odd $l$, respectively. They are called even and odd terms to correspond with the parity of $l$, and the empirical rule is then expressed by $\Delta l=\pm 1$ for radiation. The division into two groups of terms still occurs in more complicated cases, but the parity is now determined by the arithmetical sum of the $l$'s. This leads to the following method of presenting the material of a spectrum analysis. All of the even terms are written in a horizontal row, all of the odd terms in a vertical column. The wave number of each line is then placed below its proper even level and opposite its odd level. When every observable line is fitted into such a square array, the numerical classification is complete and the energy to excite any line is known. The first step in an analysis is to find a significant difference between lines which is repeated a number of times. The procedure then is to build the square array by searching for the differences which occur in either direction. It is a numerical crossword puzzle.

**Knowledge of Levels.** To complete the analysis, it is necessary to know the type of every one of the levels, and, particularly, to know the electron structure giving rise to it. This may be accomplished by resorting to Zeeman effects, which give very definite information, and to intensities which are less certain criteria. General knowledge of other spectra assists in giving information regarding the approximate position where various structures should be found. With all of this information, it has been possible to make very complete classifications of many complex spectra. For example, by putting together the results of many workers, H. N. Russell and C. E. Moore have identified the following electron structures in iron: $3d^6 4s^2$, $3d^7 4s$, $3d^8$, $3d^6 4s 5s$, $3d^7 5s$, $3d^6 4s 4d$, $3d^7 4d$, $3d^6 4s 4p$, $3d^7 4p$, $3d^5 4s^2 4p$. They are based on an analysis which included 4860 lines, classified as combinations between 181 even levels and 283 odd levels.

**Coupling Schemes.** The analysis of spectra and our ideas concerning the atom owe a great deal to the rules given by Russell and Saunders, which led to what is called Russell-Saunders coupling. It is possible to describe a great many but not all spectra in terms of these rules. The extreme exceptions are spectra resulting from atoms in which the coupling of the electrons is known as *j-j* coupling. In such a scheme the $l$ and $s$ of each electron combine to form a $j$ for that electron; the various $j$'s then combine to form $J$ for the whole atom. An $S$ or an $L$ for the atom no longer exists and names based on such quantities cannot be used. There are intermediate cases ranging all the way between the two extremes, but spectroscopists are likely to use the Russell-Saunders notation whenever possible. The spectra of heavy atoms with many electrons are sometimes so far from any standard coupling scheme that nothing beyond a numerical analysis is possible.

**Use of Series.** Series, of course, are an outstanding feature of most simple spectra. They occur in all spectra, but frequently are very difficult to find and very short. In complicated spectra, series exist which converge to different limits. This is because the removal of an electron from an atom may leave the atom in one of a great number of states. The series leading to the lowest limit are usually the most obvious and can be used to find a zero, from which to measure the levels. However, the uncertainty of such series has

resulted in a general agreement among spectroscopists that levels should be given values measured upwards from the lowest as zero. There is no ambiguity in such a scheme, and the value of a level gives at once the energy necessary for its excitation.

### HYPERFINE STRUCTURE

**Importance of Analysis.** As long ago as 1891, Michelson observed that some spectral lines actually were very close groups of lines, with the whole structure covering only a few wave numbers. Measurement and elucidation of such hyperfine structures became very important when it was realized that they could be explained by ascribing a spin and associated magnetic moment to the nucleus. This angular momentum ($I$) must be added to $J$ to obtain the possible resultants ($F$) for the whole atom, in the same way in which $L$ and $S$ were added to give $J$. Accordingly, $F$ takes all positive values from $|J+I|$ to $|J-I|$, and the level is split into a number of hyperfine structure levels obeying the Landé interval rule. The combination of two levels results in a hyperfine-structure multiplet instead of a single line; and, indeed, since several isotopes may be present with different structures, the result may be several superimposed hyperfine-structure multiplets of differing complexities. Analysis of such structures determines the $I$ of each isotope in many cases with certainty, but the measurement of the magnetic moment is much less exact because it depends on the calculation of the magnetic field produced at the nucleus by the electrons. In some cases there are small deviations from the Landé interval rule which can be ascribed to the presence of a nuclear quadrupole moment.

### MOLECULAR SPECTRA

**Vibration and Rotation.** Because a molecule is a more complex structure than an atom, it is logical to find that its spectrum is more complicated The possible states of vibration and rotation must be added to all the possible electron structures. The result is known as a band spectrum because the lines usually appear in closely packed groups, shading off toward long or short wavelengths. A line, of course, is given by the usual relation:

$$h\nu = W_1 - W_2,$$

but $W_1$ and $W_2$ are made up of electronic, vibrational and rotational energies in descending orders of magnitude. Normally, each electron transition has many vibration transitions giving different bands, and many rotation transitions giving the smaller differences appearing within the bands. For some molecules a pure rotation spectrum is observed in the far infra-red and a rotation vibration spectrum in the nearer infra-red. In any case, a detailed analysis of the band spectrum should be capable of determining the structure of the molecule, and of its modes of ionization. *See also* ATOMIC AND NUCLEUR MOMENTS; ATOMIC STRUCTURE; QUANTUM MECHANICS; SPECTRA, STELLAR AND SOLAR. A. G. S.

**SPEEDBALL,** an outdoor game which is a combination of soccer football and basketball, with scoring methods similar to those for American football. It was invented in 1921 by Elmer D. Mitchell, of the University of Michigan. The field and goals are the same as for American football, and the official ball resembles a soccer football but is slightly larger. Teams are of eleven men each.

The characteristic feature of the game is that a ground ball may not be touched with the hands but must be kicked or given impetus by the body, as in soccer football, whereas a fly ball must not be kicked but may be caught and then thrown, punted, or drop-kicked. A fly ball is one that has not touched the ground at any time since it was last played. A ground ball that is kicked into the air may be caught by any player, including the kicker himself. Thus the game is played much like basketball until the ball touches the ground and is then played like soccer football until some player catches a fly ball. However, the basketball dribble is prohibited, and there is no goal keeper with special privileges.

Points may be scored in five ways: A field goal counts 3; it is the same as a soccer football goal and is made by kicking a ground ball under the cross-bar. A touchdown, made by catching a forward pass in the end-zone, counts 2. Each of the following counts 1 point: an end kick, made by kicking the ball across the end line from within the end-zone; a drop-kick, made by drop-kicking the ball over the cross-bar from a point outside the end-zone; and a penalty kick, made from a free-kick following a foul. D. A. H.

**SPEEDWELL,** a large genus, *Veronica,* of the figwort family, comprising about 150 species of herbs and subshrubs native to temperate and colder regions. Many are grown as garden ornamentals, and some are used medicinally. They are mostly low plants, having blue, pink, or white flowers; usually the stem leaves are opposite, and the floral leaves alternate. Some 20 species occur in North America; of these, about half were introduced from Europe. Among the best known are the drug speedwell, *V. officinalis;* the purslane speedwell, *V. peregrina;* the thyme-leaved speedwell, *V. serpyllifolia;* the common speedwell, *V. arvensis;* the field speedwell, *V. agrestis;* and the ivy-leaved speedwell, *V. hederaefolia.* The name speedwell is derived from the transitory nature of the flowers, which drop at the slightest touch. *See also* VERONICA. R. P. T.

**SPELLING** may be defined as the usual method of writing words by means of letters, as distinguished from code writing and phonetic transcriptions. Since letters are in origin phonetic symbols, it follows that at some time every spelling must have been more or less phonetic, the reservation *more or less* deriving from the fact that generally the letters are inferior in number to the phonemes they have to represent, with the result that one letter may frequently have more than one phonetic value. Since languages change constantly, however, it inevitably happens that, unless the spelling is reformed from time to time, it will diverge more and more from the pronunciation, up to a point where it becomes almost ideographic; the pronunciation of the modern English words *Leicester, Worcester, cough, though, knight, know,* and *naughty* has now so little relation to the spelling that these words have to be learned one by one, not on the basis of any general rule of pronunciation. While this happens to a greater or smaller extent in many languages, there is no doubt that a few languages, such as Serbian, Lithuanian and Basque, have a spelling that corresponds almost perfectly with pronunciation; but others, like French, have a spelling that is widely divergent. Antoine Meillet observed that the spelling of Spanish was excellent (perhaps an overstatement), and the spelling of Italian good; if his standard were applied to other languages, German and Russian spellings would be considered mediocre, French worse, and English worst of all (with the possible exception of Irish and Tibetan).

The main reason for the peculiarity of English spelling lies in the very formation of the English language, for it has kept or reintroduced the old historical spelling of the four principal languages of which it is formed: Old English, Old French, Latin, and Greek. In words of Old English

origin, the sound *i* became *ai* in open syllables (*bide, hide, wife, shine*); but this did not happen in *machine,* a word of late French origin. Likewise, no rule whatever can be given for the pronunciation of *g* in front of the vowels *e* and *i,* for *g* has preserved a velar articulation in words of either Old English origin (*geese, giddy, gild, begin*) or Norse origin (*get, gift*); whereas in words of French, Latin, and Italian origin it has mostly the Old Romance (Old French and Italian) value of *dž* (*general, gigantic*). In Greek words, English, like French and German, has preserved the standard Latin transcription and pronunciation, not the Greek: this produces such spellings as *physiology, photography, chemistry, character, chorus.* This transcription once introduced, even new words formed with Greek elements, such as *telegraph* and *telephone,* are spelled in the same way.

In general, apart from Greek words, English spelling reflects the pronunciation of English as it was several centuries ago. Thus the Old French words, for the most part, preserve the pronunciation they had at the time of the Norman Conquest, except for their accent, which, under the influence of Old English, was usually shifted to the root syllable. On this point English *feast, haste, saint, point, danger, cloister, chamber, general* may be compared with Modern French *fête, hâte, saint, point, danger, cloître, chambre, général.* Since French also has preserved the spelling of that period as a general rule, it so happens that many words are spelled the same way in French and in English (*danger, point, saint*) but pronounced quite differently, the English pronunciation being much more archaic, and therefore more phonetic (nearer to the spelling).

Both in French and in English, the learned influence has introduced letters into the spelling of certain words in order to bring them closer to the true or supposed Latin original. Sometimes English has gone further than French in this trend, spelling *doubt* with a silent *b,* for example, out of regard for Latin *dubitare,* while French preserves the form *doute.* More frequently, however, French has gone further than English, spelling *temps* (from Lat. *tempus*) with a silent *p,* for example, while English preserves the form *tense.* French *poids* and English *poise* both derive from Latin *pensum,* a fancied connection with Latin *pondus* being responsible for the silent *d* in the French spelling.

The relationship between the spoken and the written word is so close, and in Western culture the importance of the book and the journal is so great, that sooner or later, in many words, letters that should not be pronounced come back to life again. In the word *often,* for example, the *t* is heard more and more frequently (though not in *soften, hasten, listen,* and *fasten*); in *fault, altar, vault,* and *falcon* the *l* was formerly not pronounced. The most important and comprehensive examples of this phenomenon of revival are furnished, however, by French, Latin, and Greek words containing the letters *th* and initial *h.* When Greek words were transcribed in Latin characters, the symbol *th* was used for the sound represented by the letter *θ,* and the symbol *h* was used for the sound represented by the so-called "rough breathing." In the Middle Ages the initial *h* was not pronounced and *th* was pronounced *t*; in the development of the English language, however, analogy with words from Old English in which these symbols had the value of *h* and of *θ* (e.g., *house, high, he; thin, thick, death*) brought about a similar pronunciation when the symbols were found in Greek and Latin words, and usually when they were found in French words. As a result, English has such pronunciations as *hemisphere, hemophile, hospital, host, human, herbarium, theology, theatre,* and *mathematics.* Only a few French words kept the silent *h*: e.g., *heir, honest, honor, hour;* others oscillate: e.g., *herb, humor, homage, humble.* Another example of revived pronunciation may be found in the English word *corpse,* derived through Old French from Latin *corpus.* In this case the letter *p* was introduced through learned influence and then pronounced; the Old French word was *cors.* Modern French *corps* also contains an inserted *p,* but it is not pronounced; and the *p* in Modern English *corps,* which came from the French much later than *corpse,* is likewise unpronounced.

It also happens that letters introduced erroneously under learned influence came to be pronounced, thus altering the nature of the words in which they appear, and producing etymological monstrosities. Thus Latin *letalis* ("deadly"), from Latin *letum* ("death"), was somehow picturesquely connected—by what is usually called popular or false etymology—with Greek *Lethe,* the river of oblivion; the result was *lethal,* with a pronounced *th.* In like manner, the *h* in *author* and *anthem* was introduced by mistake, and the *th* in those words is now pronounced as a fricative. The old pronunciation is still preserved, despite the spelling, in *Thomas, Thames,* and *Anthony,* though the pronunciation of the last two wavers. *Delight* was once spelled *delite,* and then connected with *light; rhyme* was once regularly written *rime.*

The eccentricity of English spelling is clearly demonstrated by two sets of facts. First, the same symbol (letter or group of letters) often represents two or more sounds (e.g., *cough, tough, enough, though, through, plough, hiccough;* also *ghost, night; create, heat, great, threat; convey, key; hate, hat, father; few, sew; low, how*). Secondly, the same sound is expressed by two or more different symbols (e.g., *Thomas, tide, ptomaine, phthisic; who, two, flew, flue, food, rule, route, rheum; machine, believe, receive, weed, heat, complete; let, Thames; ashes, caution;* as an advertising slogan puts it, *eye it, try it, buy it*). It even happens frequently that two different words, with different sounds and meanings, are written in the same way: for example, *bow* (verb and substantive), *contrast* (verb and substantive), *contract, present,* and *refuse.* It is possible for *w* and *y* to have the value either of vowels (as in *symbol, new*) or of consonants (as in *yes, water*).

Many believe that the complicated system of English spelling has few, if any, advantages, and many great disadvantages. The idea of reforming it has made little headway, however, even though reform measures have been fervently and repeatedly advocated by distinguished men, George Bernard Shaw among them. Such slight changes as *thru* for *through, boro* for *borough,* and *altho* for *although* have found little favor; the American spellings *labor, color,* and *endeavor* have not penetrated into England, despite the recommendation of H. W. Fowler in *A Dictionary of Modern English Usage.* Many systems of phonetic or simplified spelling have been advocated, of varying degrees of merit; none has found much acceptance. G. B.

**SPELLMAN, FRANCIS JOSEPH** [spɛ'lmən] (1889- ), American cardinal and archbishop, was born in Whitman, Mass., May 4, 1889. He was educated at Fordham University and the University of the Propaganda in Rome, graduating with the S.T.D. degree in 1916. He then became an assistant to All Saints' Parish, Roxbury, Mass., and in 1918 joined the editorial staff of the *Boston Pilot.* In 1922 he was appointed assistant chancellor of the Boston archdiocese, and in 1925 was made attaché to the Papal Secretariat of State. Named auxiliary bishop of Boston in

1932, he was promoted to the archbishopric of New York in 1939, and in the same year was appointed military vicar of the armed forces of the United States. He was created cardinal in 1946. During the Korean war he made Christmas visits to the battlefront during each of the years 1951, 1952, and 1953. Cardinal Spellman's publications include *The Word of God* (1922) and *In the Footsteps of the Master* (1924), both translations; *The Road to Victory* (1942); *Action This Day* (1943); *The Risen Soldier* (1944); *No Greater Love* (1945); and a best-selling novel, *The Foundling* (1951). FRANCIS JOSEPH CARDINAL SPELLMAN

BROWN BROTHERS

**SPELMAN COLLEGE** [spɛ′lmən], an accredited, privately controlled college of arts and sciences for Negro women. It is affiliated with the Baptist Church, and is situated on a campus of 23 acres in Atlanta, Ga. A member of the Atlanta University system, the college is operated with Morris Brown College, Clark College, Morehouse College, and Gammon Theological Seminary. The college was founded by the Woman's American Baptist Home Mission Society. First instruction was offered under the name of the Atlanta Baptist Female Seminary in 1881. The charter was granted in 1888. The name was changed to Spelman Seminary in 1884, in honor of Mrs. Lucy Henry Spelman, and to Spelman College in 1924. The Spelman College Nursery School was established in 1930.

Only the A.B. and the B.S. degrees are offered. There is some scholarship aid. Opportunities for self-help enable some of the students to earn part of their expenses. Dormitories and dining halls are provided. Out-of-city students live on the campus unless permission is granted to live elsewhere. *For statistics see* COLLEGES AND UNIVERSITIES. J. R. To.

**SPELT,** *Triticum spelta,* a variety of wheat with slender, loose, bearded ears and small triangular grains. In former times spelt was common and was especially grown in poor soils. Today its cultivation is comparatively unimportant. The grain which in the United States is generally called spelt is really emmer. The grains are held tightly in the chaff and are not hulled in threshing. *See also* WHEAT. C. K. H.

**SPEMANN, HANS** [shpe′mɑn] (1869-1941), German physician, biologist, and zoologist, was born in Stuttgart, June 27, 1869. For a time he worked in his father's publishing business, then became interested in medicine and entered the University of Heidelberg, where he studied comparative anatomy and took a degree in medicine. Spemann studied zoology, botany, and physics at the Zoological Institute in Würzburg from 1894 to 1904, and his instructors there, Boveri, Sachs, and Roentgen, all exercised a profound influence upon his career. He was appointed professor of zoology at Rostock University in 1908 and became director of the Kaiser Wilhelm Institut at Berlin-Dahlem in 1914. Five years later he was appointed professor of zoology at the University of Freiburg and held the post until his death. The greater part of Spemann's researches were in the fields of experimental biology and experimental zoology, particularly among amphibia. In embryology he succeeded in accomplishing complete development of frogs' eggs by mechanical and chemical stimulation and without fecundation. Spemann received the 1935 Nobel Prize for physiology and medicine for his discovery of the organizer effect in embryonic development. He demonstrated that certain parts of tissue of the embryo contain comparatively simple chemical substances that organize and direct the development of an embryo. Spemann died at Freiburg on Sept. 12, 1941. D. D. M.

**SPENCE, THOMAS** (1750-1814), British bookseller and economic reformist, was born in Newcastle-on-Tyne, June 21, 1750. After his education in local schools he became a clerk, later teaching for several years. Early in his career Spence became deeply interested in the question of land tenure and devoted the rest of his life largely to campaigning for reforms in the proprietary system. In 1775 he wrote a pamphlet, *The Real Rights of Man,* proposing the abolition of landlordism and urging land tenure on a semisocialistic basis; money from rents would be divided among the parishioners, but no taxes would be levied. Other features of his communal system were compulsory military training and a sabbath every five days. In later pamphlets Spence elaborated on these proposals and outlined a Utopian state named "Spensonea." In 1801 Spence was imprisoned for a year and fined for seditious libel. He attracted many disciples known as Spenceans who, after his death in London, Sept. 8, 1814, continued to advocate his views. G. Q.

**SPENCER,** the name of a prominent English family, whose several branches were honored with the earldoms of Sunderland and Spencer and the dukedom of Marlborough. The family traces its descent from Robert Despencer, steward to William the Conqueror, and, through the brothers Hugh le Despenser, the favorites of Edward II, to Sir John Spencer (d. 1522), who acquired the estates of Wormleighton and Althorp. Sir John Spencer's great-great-grandson, Robert Spencer, first Baron Spencer of Wormleighton (d. 1627), was reputed to be the wealthiest man in England.

**Earls of Sunderland.** Robert Spencer's grandson, Henry Spencer (1620-1643), was created first Earl of Sunderland some three months before his death at the first Battle of Newbury (1643). His only son, Robert Spencer (1640-1702), by his wife Dorothy, who was the well-known "Sacharissa" of Edmund Waller and the daughter of Robert Sidney, Earl of Leicester, succeeded him in the earldom and, after serving on embassies to Madrid, Paris, and Cologne in 1671-1678, was appointed secretary of state for the northern department in 1679, becoming a member of the powerful inner cabinet. Two years later he was dismissed from the Privy Council in consequence of having adopted the side of the exclusionists, but the following year he was reconciled to the king. So successful was Sunderland in cultivating the influence of the Duchess of Portsmouth and the French ambassador, Barillon, that he was reappointed to his secretaryship in 1683 and grew increasingly successful in his rivalry with Rochester

and Halifax. On the accession of James II in 1685 he was given the post of lord president, in addition to that of principal secretary of state, and succeeded in remaining in the king's favor despite the denunciations of Monmouth and Rochester. In 1688, having joined the Catholic party, he renounced Protestantism but continued to correspond with the Prince of Orange, whom he had cultivated through his uncle Henry Sidney. In the crisis of 1688 he came under suspicion for failing to suggest adequate remedial measures, was dismissed, and fled to Rotterdam, but he returned to England three years later, having convinced William III that his services were indispensible, and reverted to Protestantism. He soon regained his position of influence and successfully persuaded William to support a united Whig ministry. As yet without office, he was appointed lord chamberlain and one of the lords justices in 1697, but the general distrust in which he was held, even by the Whigs, compelled him to resign these offices later in the year. Sunderland is generally considered one of the craftiest politicians of English history.

Robert Spencer was succeeded in the earldom by his second son, Charles Spencer, third Earl of Sunderland (1674-1722), known equally for his library of rare books and for his statesmanship. He entered Parliament in 1695, and in 1700 married Lady Anne Churchill, daughter of the earl (later duke) of Marlborough, a step of political importance, for his father-in-law was thus drawn toward the Whigs. In 1705 he was appointed envoy extraordinary to Vienna and the following year was named secretary of state for the southern department, becoming a member of the powerful Whig junto of five; but, through the machinations of the High Church Tories and his rival Harley, he was dismissed by Queen Anne in 1710. Throughout the remainder of Anne's reign Sunderland was in communication with the court of Hannover and their agents, and on the accession of George I in 1714 he was made lord lieutenant of Ireland, though he had hoped to be named one of the lords justices. The following year he exchanged his viceroyalty to join the cabinet as Lord Privy Seal and in 1717 succeeded in obtaining the dismissal of Walpole and Townshend and his own appointment as First Lord of the Treasury. He was forced to resign in favor of Walpole in 1721, owing to his connection with the South Sea Bubble, but continued to have great influence with George I. Sunderland's library at Althorp was described as the finest in Europe. His eldest son, Robert, succeeded him in the earldom, and on the latter's death in 1729, his second son, Charles (1706-1758), succeeded as fifth Earl of Sunderland and, through his maternal aunt, Henrietta, Duchess of Marlborough, as third Duke of Marlborough. Sunderland's third son, John, became founder of the cadet branch holding the earldom of Spencer.

**Earls of Spencer.** John Spencer (1734-1783), son of John Spencer, the youngest son of the third earl of Sunderland, was created earl of Spencer in 1765. He was succeeded by his son, George John (1758-1834), who was Lord of the Admiralty from 1794 to 1801 in the Pitt ministry and was largely responsible for the great naval victories at St. Vincent and Camperdown, as well as for singling out Nelson for independent command and sending him into the Mediterranean to win the Battle of the Nile. He was home secretary in 1806-1807. His eldest son, John Charles (1782-1845), Viscount Althorp, succeeded as third Earl Spencer in 1834. On entering Parliament in 1804, Althorp supported Pitt, later joining the advanced Whig Party, and, after the close of the war in 1815, gave a strong ear to the grievances of the working classes. In 1830 he became the leader of the Whig opposition, and on Wellington's resignation was named Chancellor of the Exchequer and leader of the House of Commons in the Grey ministry. He showed great zeal in working for the final passage of the Reform Bill, but with the rise of Peel his influence declined, though he retained office until 1834. He was succeeded in the title by his brother Frederick (1798-1857), whose son, John Poyntz Spencer (1835-1910), became fifth earl. The latter entered Parliament in 1857 and in 1868 was named lord lieutenant of Ireland, where he earned a reputation for firmness in maintaining order. He left Ireland on the fall of the Gladstone ministry in 1874 and, on the formation of the second liberal ministry in 1880, joined the cabinet as Lord President of the Council, but in 1882 he was reappointed to his former position in Ireland. His severity in punishing the Phoenix Park murderers of Lord Frederick Cavendish made him unpopular with the Irish, but he succeeded in restoring order. He resigned in 1885 and the following year again took office as president of the council in Gladstone's third ministry, supporting the latter's Home Rule Bill. He was First Lord of the Admiralty, 1892-1895, in Gladstone's fourth ministry, and from 1902 to 1905 was liberal leader in the House of Lords.

**Dukes of Marlborough.** The Spencer family fell heir to the dukedom of Marlborough in 1733, on the death of Henrietta, Duchess of Marlborough, daughter of the first duke and maternal aunt of Charles Spencer (1706-1758), fifth Earl of Sunderland and third Duke of Marlborough. *See also* MARLBOROUGH, EARLS AND DUKES OF. C. W. D.

**SPENCER, HERBERT** (1820-1903), English philosopher, was born at Derby on April 27, 1820. In his philosophy he was a champion of evolutionism, *laissez faire,* and the conception of philosophy as the unification of all sciences, and he highlighted these and other intellectual currents of his age. A complete lack of formal schooling and an impatience with the books of his predecessors made him rely on getting his knowledge wherever he could.

The key to his system of unified science, *First Principles* (1862), maintains in its opening chapters that nothing can be known of ultimate reality. This Unknown lies beyond the field of scientific investigation; religion merely rationalizes and reveres it in metaphor. The second part of this volume sets forth a cosmic theory of evolution which, he holds, is a universal principle underlying and summarizing all fields of inquiry. In 1852, seven years before the publication of Darwin's *Origin of the Species,* he had already brought out an essay, *The Development Hypothesis,* elaborating an earlier form of evolutionary theory by Von Baer. From basic laws of physics and from the idea of change, Spencer proceeds to define evolution as "an integration of matter and a concomitant dissipation of motion; during which the matter passes from an indefinite, incoherent homogeneity to a definite, coherent heterogeneity; and during which the retained motion undergoes a parallel transformation." All things have a common origin, but by the inheritance of characteristics acquired in adapting themselves to their environment, they become differentiated; when everything is adapted to its environment, a coherent, ordered universe emerges. Ultimately each thing will achieve complete adaptation, but such a state is unstable. The final stage of evolution is therefore but the first stage of dissolution, and then, in a great cycle, dissolution is followed by evolution again.

The key principles of what he called the Synthetic Philosophy were thereby stated at the very outset of Spencer's program; succeeding volumes needed only to interpret the particular sciences in terms of them. *Biology* followed (2 vol.

1864-1867), then *Psychology* (2 vol. 1870-1872), *Sociology* (3 vol. 1877-1896), and *Ethics* (2 vol. 1892-1893). Spencer's major contributions to scientific enterprise were in sociology, on which he published two other treatises, *Social Statics* (1850) and *The Study of Sociology* (1873), and eight volumes of classified data. Societies are described as evolving organisms similar to biological organisms. They may organize and control their own processes of adaptation, and thereby develop into militaristic states; or they may permit free and plastic adaptation, and thereby develop into industrial states.

The inevitable course of evolution, however, makes adaptation "not an accident but a necessity." As a consequence of his faith in the cosmic force of evolution Spencer defends a social philosophy of *laissez faire*. The individualism underlying this philosophy is succinctly expressed in the *Ethics*, wherein "every man is free to do what he wills, provided he infringes not the equal freedom of any other man." His *Autobiography* (2 vol. 1904) again reveals him to be an ultra-individualist both by temperament and heredity, a man of great self-discipline and productivity, but with little of humor or poetry about him. He died at Brighton on Dec. 8, 1903. A. G. Sm.

**SPENCER,** a city in northwest Iowa, the county seat of Clay Co., situated at the confluence of the Little Sioux and Ocheyedan rivers, about 80 mi. northeast of Sioux City. Founded in 1871, the community was incorporated in 1880. In June 1931 a fire practically destroyed the business district, causing approximately $2,000,000 worth of damage. Within a year most of the section was rebuilt. A mayor and council govern the city of Spencer. Of interest is a large county fair held every September in Spencer. Spirit Lake, the scene of an Indian massacre in 1857, is 18 mi. north. The Chicago, Milwaukee, St. Paul and Pacific and the Minneapolis and St. Louis railroads provide transportation. Spencer is the trade center and shipping point for a region where the growing of corn and soybeans and the raising of hogs and cattle are important. The local industries, which are dependent on the district's agricultural interests, process feed, meat, and dairy products. Pop. 1950, 7,446.

**SPENCER,** a town in Worcester Co., in central Massachusetts, located about 10 mi. west of Worcester. It is served by the New York Central System. The chief industry is the manufacture of shoes. William Howe, inventor of the truss bridge, Tyler Howe, maker of the spring bed, and Elias Howe, inventor of the sewing machine, were all born in Spencer. The town was founded by Samuel Bemis in 1721 and incorporated in 1753, and has the town meeting form of government. Pop. 1950, 5,259.

**SPENDER, STEPHEN** (1909- ), English poet and critic, was born in London, Feb. 28, 1909, and educated at University College School and at University College, Oxford. A member of the revolutionary group of writers that included W. H. Auden, Christopher Isherwood, Cecil Day Lewis, and Louis MacNeice, he first attracted notice with *Poems* (1933). Several pieces in this volume derive technically from Walt Whitman and D. H. Lawrence; praising labor and denouncing capital, they are more political and more violent than most of the work of Spender's friends. Other poems in the volume on pylons, trains, and aerodromes, for example, reveal Spender's lyric power. *Vienna* (1934), a long poem, celebrates the abortive revolution of Viennese socialists in 1934 against the Dollfuss government. In 1938 Spender published *Trial of a Judge*, an antifascist verse play in the manner of Auden, and, after a visit to Spain, he edited with John Lehmann *Poems for Spain* (1939), an anthology occasioned by the Spanish Civil War. In *Forward from Liberalism* (1937) he had maintained the individualism of the artist against Marxist demands; and after the German-Soviet pact of 1939, like most English leftists, he modified his political sympathies. Spender's subsequent volumes of poetry, *The Still Centre* (1939), *Ruins and Visions* (1942), and *Poems of Dedication* (1946), more self-centered than his earlier works, lack their conviction and power.

From the outset of his career Spender showed himself to be an excellent critic, and *The Destructive Element* (1935), a volume of essays on contemporary literature, attracted almost as much attention as his poems. In 1940 he became associated with the magazine *Horizon*, to which he contributed annual surveys of poetry. Among his works of fiction are *The Burning Cactus* (1936) and *The Backward Son* (1940). *European Witness* (1946) is a survey of postwar Germany. W. Y. T.

**SPENGLER, OSWALD** [shpɛ′ŋlər] (1880-1936), German historian and philosopher, was born May 29, 1880, at Blankenburg in the Harz Mountains. He studied philosophy, history, mathematics, and art at the Universities of Munich and of Berlin, where he received his doctoral degree in 1904. He started his academic career as a teacher of mathematics at the University of Munich.

In 1918 there appeared the first volume of his remarkable philosophy of history, *Der Untergang des Abendlandes* (*The Decline of the West*, 1926-1928), the second volume appearing in 1922. In this, his most important work, Spengler predicted the disintegration of Western European and American civilization after a violent "age of Caesarism," arguing by detailed analogies with other civilizations and interpreting history as the life of nine organic cultures: Egyptian (3400 B.C.-1205 B.C.), Indian (1500 B.C.-1100 B.C.), Chinese (1300 B.C.-A.D. 200), Classical (1100 B.C.-400 B.C.), Byzantine (A.D. 300-1100), Aztec (A.D. 1325-1500), Arabian (A.D. 300-1250), Mayan (A.D. 600-960), and Western (A.D. 900-2400). With a great variety of factual material Spengler attempts to substantiate two propositions about these cultures. First, all cultures follow the same pattern of growth and decay in approximately the same length of time. They pass through the stages of pre-culture, culture, and civilization, and are marked by identical crises. Alexander, for example, plays the same role in Classical culture as Napoleon in Western culture; Pythagoras as Luther; Aristotle as Kant; Stoicism as Socialism. Second, each culture has its unique "soul," or pattern of experience and creation, expressed in its forms of art, thought, and action. Thus the Western "Faustian" soul is characterized by a yearning for infinity, which is equally expressed in the Gothic cathedral, the infinitesimal calculus, the music of Bach, world-wide imperialistic diplomacy, the radio, and modern techniques of credit banking.

In several other books, of which perhaps the most significant are *Der Mensch und die Technik* (1931) (*Man and Technics*, 1932) and *Jahre der Entscheidung* (1933) (*Hour of Decision*, 1934), Spengler wrote of the political and spiritual predicament of Germany in the aftermath of World War I. M. C. Be.

**SPENSER, EDMUND** (c.1552-1599), English poet, was born in London of humble stock, though his family was related to the wealthy house of Sir John Spencer of Northamptonshire. Though poor, he was somehow helped to get the best available education of the time, first at the Merchant

Taylors School under the great teacher Richard Mulcaster, then at Pembroke College, Cambridge. His talents were early recognized, and won him introduction to employment and patronage under the Bishop of Rochester, and later under the Queen's favorite, the Earl of Leicester. Thus he found access to the Court, and was brought into association with Sir Philip Sidney, Sir Fulke Greville, and other literary men. In 1579 he published *The Shepherd's Calendar* which revealed to the literary world undiscovered poetical resources in the English language of the time. It met ready and long-lived success. Spenser's hopes of preferment were running high, when for some unknown reason, perhaps imprudent utterance, he was sent out of the way to Ireland as secretary to Lord Grey. In that rough and turbulent country, except for two visits of a year or more in London, he lived out the rest of his hard life, solaced by the joy of poetical composition and the wild beauty of Ireland, but irked by unstable conditions and the deferred hopes of his ambitions. His last ten years he spent at Kilcolman, his estate of three thousand acres and a castle, about thirty miles north of Cork. Late in 1598, during the Tyrone rebellion, his castle was burned, and Spenser escaped to London, to die there Jan. 13, 1599. He was buried in Westminster Abbey.

Spenser was twice married, first about 1580 to an unknown woman who died early, again to Elizabeth Boyle in 1594. He had at least three children. In various poems he has recorded an unrequited passion and "long affliction" for a fair unknown disguised under the name Rosalind. His nature was composed of two warring elements, strong worldly ambition and high poetic idealism. As a man of the world he had a qualified success. Queen Elizabeth appreciated him, and probably would have done more for him had it not been for her shrewd but prosaic minister, Lord Burghley. Throughout his rough career his production of poetry was prolific, and probably constant, though he published only on occasion of his visits to London, but then in quantity. In his thirty active years he produced over 47,000 lines of published verse, besides more than twenty unpublished works now lost. He began at about seventeen with some precocious translations of twenty-one sonnets from French and Italian. Ten years later came *The Shepherd's Calendar,* and after ten more years, on his first return to London, three books of his *Faerie Queene* (1590) and his *Complaints* (1591). *Complaints* was a selection mostly of studio pieces, elegies, visions, allegories, and translations, which had been produced during the previous years. One of them, however, *Mother Hubberd's Tale,* a beast fable, was a bitter satire on conditions in Church and State, in part aimed at Lord Burghley and his son, Sir Robert Cecil. It hurt his chances for preferment, and perhaps had something to do with his going to Ireland, though the Queen herself was delighted with his *Faerie Queene,* well knowing what so great and promising a poet was worth in lending luster and fame to her reign. The year 1591 also saw the private publication of *Daphnaida,* a lovely if formal elegy for the dead wife of a young courtier. In 1595 appeared his charming autobiographical pastoral poem, *Colin Clout's Come Home Again,* together with *Astrophel,* a long-delayed, perfunctory elegy for Sir Philip Sidney; and in the same year his *Amoretti and Epithalamion,* consisting of eighty-six love sonnets, some of the best of that sonneteering generation, and one of the most glorious wedding-songs ever devised, in celebration of his second marriage. In 1596, again in London, he published Books IV-VI of *The Faerie Queene,* and reissued Books I-III. Also in 1596 appeared his *Four Hymns,* in honor of Love, Beauty, Heavenly Love, and Heavenly Beauty, a quartette embodying, in lofty and varied word-music hitherto unheard in English, the Platonic ideas of secular love and beauty and of the Christian mystical union with God which were still prevalent in Italy and France. Lastly, in 1596 appeared *Prothalamion,* a much admired betrothal ode in honor of a double spousal of four young aristocrats. Thirty-four years after his death his long prose treatise, *A View of the Present State of Ireland,* saw the light. It was written near the end of his life, and recommended rather drastic procedure with that unhappy country. He had planned twelve books in all for his *Faerie Queene,* but only two cantos, a possible fragment of a seventh book, have been found.

Charles Lamb called Spenser the poet's poet. He may have said more than he realized, for the epithet holds surprisingly. One does not have to be a poet to appreciate Spenser, but one must have enough poetry in him to respond to the word-music of Spenser, to his shifting color and pageantry, to his power of suggestion, where more is meant than meets the ear, and one should have a mind for ideas and conceptions that outstrip the mere limits of mundane life. Perhaps Lamb was thinking only of Spenser's power to make other men sing. Spenser discovered a new music in the rejuvenated English language of his time, and called it forth in a wide variety of pitch and cadence. Other poets have caught his strains and echoed them, from Marlowe and Shakespeare to Tennyson and T. S. Eliot. The "Spenserian stanza" of eight five-stress lines plus one six-stress line, rhyming *ababbcbcc,* is the most important and original metrical invention by any single English poet. It has since been used by Pope, Thomson, Burns, Scott, Wordsworth, Byron, Shelley, Keats, Tennyson, and a host of lesser poets.

The England of Elizabeth was provincial and knew it. Spenser was its richest importer and disseminator of poetic materials and ideas. He engrafted in English poetry the Italian Platonic ideas of love and beauty, imagery from Petrarch, legend from Ariosto and Tasso, theories of the art and language of poetry from France; he reopened infinite poetic resources from the Latin and Greek Classics; and he revived the neglected wealth of material from English history and the tradition of chivalry. All this and more he imbued with native English vigor and quality, and under his hand it became poetry with the peculiar power of enriching the poetry of others. He idealized England and the Queen, and was convinced that if he could kindle the imagination of his fellow countrymen by his poetry, he could thus bestir them to a realization of their greatness in the making of a better world. He believed in the subtle kinetic power of poetry over the minds and wills of men.

A high idealist, Spenser, like Dante and Shelley, found allegory and parable his natural means of expression. But he clothed them with splendor of pageantry and variety of music, with charm of manner and vigor of action, and with the reality of essential values, so that they find response not only in many a professed poet, but in any one who has poetic sense. *See also* FAERIE QUEENE, THE; SHEPHERD'S CALENDAR, THE.

C. G. O.

**SPENSERIAN STANZA,** so named from Edmund Spenser's use of it in *The Faerie Queene,* an ample, sonorous verse form composed of nine lines, the first eight in iambic pentameter and the last an alexandrine, in iambic hexameter. The rhyme scheme is *ababbcbcc.*

> At length they spide, where towards them with speed
> A Squire came gallopping, as he would flie;
> Bearing a little Dwarfe before his steed,
> That all the way full loud for aide did crie,

That seem'd his shrikes would rend the brasen skie:
Whom after did a mightie man pursew,
Ryding upon a Dromedare on hie,
Of stature huge, and horrible of hew,
That would have maz'd a man his dreadfull face to vew.

The Spenserian has been most used for romance in the grand style, and for philosophic poems. It has a sustained rhythmic sweep, and the final long line adds an epic dignity. It was imitated by Spenser's followers in the seventeenth century, and again by Thomson, Shenstone, and others in the mid-eighteenth. Burns, Byron, and Tennyson have all written important poems in this great stanza, but the best-known modern examples are in Keats's *The Eve of St. Agnes* and in Shelley's *Adonais.* R. Bn.

**SPERONI, SPERONE** [spero'ni] (1500-1588), Italian writer and linguist, was born at Padua in 1500. He studied at Bologna, taught logic at Padua until 1528, and came to enjoy a great reputation as a man of letters. He died at Padua in 1588.

Speroni wrote lyrics, essays on the *Aeneid,* the *Divine Comedy,* and the *Orlando Furioso,* several dialogues, and the tragedy *Canace,* composed in 1542 and published in 1546. *Canace* purported to be a perfect imitation of Greek tragedies according to Aristotle's rules—a claim which was soon challenged and started a literary war that lasted for fifty years. Some of the characteristics of the play are an excess of horror, an absence of moral aims, and some important metric reforms. Of Speroni's dialogues, which include *Delle lingue, Della retorica, Della cura familiare, Dell'amore, Della dignità,* and *Delle donne,* the most important is *Delle lingue.* In this he followed Dante and Bembo in defending the new Italian *volgare* against Latin and Greek, maintaining that it was perfectly capable of fulfilling the artistic function of a great new language. Speroni's dialogue had a great influence in Italy and also in France, where it directly inspired Du Bellay's famous *Deffense et illustration de la langue françoyse* (1549). G. B.

**SPERRY, ELMER AMBROSE** (1860-1930), American electrical engineer and inventor, was born in Cortland, N. Y., on Oct. 12, 1860. He attended the State Normal School in Cortland and Cornell University. Sperry perfected an electric arc lamp in 1879 and in 1880 organized the Sperry Electric Co. in Chicago to manufacture arc lamps and dynamos. He invented the first electric chain mining machine in 1888. He also designed an electric locomotive and an electric driving apparatus for trolley cars, and as a result of these developments founded the Sperry Electric Railway Co. in 1890. Sperry sold the company to General Electric Co. in 1894. At the turn of the century, Sperry founded an electrochemical laboratory in Washington, D. C., where, with the assistance of C. P. Townsend, he developed a process for the manufacture of pure caustic soda and perfected a new and improved method for salvaging tin from waste metal products. In 1918, Sperry invented a high-intensity arc searchlight which was several times as bright as any previous searchlight. This was presently adopted for military and naval use.

Sperry's greatest fame came from his adaptations of the gyroscope to practical problems. He organized the Sperry Gyroscope Co. in Brooklyn, N. Y., in 1910 and remained as its head until 1929. He invented the gyrocompass, which is based on the rotation of the earth and which superseded the magnetic compass. He developed electrically driven gyro-stabilizers for maintaining ships on an even keel and for keeping airplanes in a horizontal position. Sperry also designed gyro-directed aerial torpedoes, gyro pilots for steering ships automatically, and devices that dealt with submarine detection and anti-aircraft gunnery. During his lifetime, he took out about 400 patents.

Sperry published numerous papers and received many honors. In 1914, he was awarded a prize by the Aero Club of France for his airplane stabilizer. The French Institute decorated him with two medals, in 1914 and 1929, and he was given the John Fritz Medal in 1927. Sperry was the recipient of three honorary doctorates and was decorated by the tsar of Russia and the emperor of Japan. He was a founder and charter member of the American Institute of Electrical Engineers and of the American Electrochemical Society. Sperry died in Brooklyn, N. Y., on June 16, 1930. *See also* Gyrocompass; Gyroscope. I. B.

**SPEYER** or **SPIRES** [shpai'ər, spai'ərz], an industrial town in the state (*Land*) of Rhineland-Palatinate, in southwestern Germany, the former capital of the Bavarian Palatinate. It lies in the broad Rhine River valley, astride the mouth of the Speyerbach, in a fertile agricultural region. It was known to the Romans as Augusta Nemetum and to the Gauls as Noviomagus. Located on an easy migration route, Speyer was frequently destroyed by barbarians during the *Völkerwanderung.* It was a bishopric in the seventh century and became a free imperial city in the thirteenth century; it was at the Diet of Speyer in 1529 that adherents to the Reformed faith received the name of Protestants. Destruction of Speyer by the French in 1689 was so severe that recovery came only in the twentieth century. The cathedral, the largest Romanesque church in Germany, dates from the eleventh century; it has been repeatedly destroyed and contains the remains of a number of German emperors. From 1801 to 1814 Speyer was part of Donnesberg. Industries include breweries, wine cellars, brickyards, iron works, cotton-spinning mills, and tobacco and shoe factories. Pop. 1953, 35,000. C. C. H.

**SPEYER, DIETS OF,** formal public assemblies of the princes and councilors of the Holy Roman Empire, held several times during the Reformation at Speyer (Bavaria), notably in 1526 and 1529. In the Diet of 1526 the Lutheran princes, who for their common defense had formed the Alliance of Torgau in May 1526, secured the decision that pending the convocation of a general council each might adopt with regard to the Edict of Worms (which in 1521 had forbidden all religious innovations) such attitude as he could justify before God and emperor. Territorial rulers thus received implicit permission to introduce the Reformation into their lands. In the Diet of 1529, Pope Clement VII and Emperor Charles V being no longer at war and the reformers less solidly united, the Recess of 1526 was rescinded, the Edict of Worms was reaffirmed, and it was decreed that while Lutheranism might remain where it was established, it could not be extended, whereas Catholicism was to be everywhere free. The Reformer princes and fourteen important cities protested. The name Protestant dates from this protest made in behalf of Lutheranism. N. J. T.

**SPEZIA, LA.** *See* La Spezia.

**SPHALERITE** [sfæ′lərait], or zinc blende, is the outstanding ore of zinc. In composition, it is zinc sulphide, ZnS. Up to eighteen per cent of iron may also be present. The color of the pure zinc sulphide is white, but enough iron is invariably present to color sphalerite yellow, brown, red, or black. The miners' term for red sphalerite is ruby jack, and for the more common black variety, black jack. Regardless of color, the streak of sphalerite is light yellow. Another distinctive characteristic is six directions of cleavage. Black jack has a metallic luster, but the common brown sphalerite has a distinctive resinous appearance. Geologically, sphalerite is found under relatively low temperature conditions. The large Mississippi Valley zinc deposits are of disputed origin. The depositing solutions were either circulating ground waters or magmatic waters of exceptionally low temperature type. Elsewhere, as in the Rocky Mountain area, sphalerite occurs with galena in veins of the low and intermediate temperature type. It is also found, but much more rarely, in contact metamorphic deposits. The United States is the leading producer of zinc. Over one fourth of the domestic output is from the Joplin or Tri-state District, which includes adjoining corners of Missouri, Kansas, and Oklahoma. Idaho and New Mexico may also be included as valuable sphalerite-producing regions within the United States. Large foreign sources of sphalerite are found in Canada, Mexico, Australia, Germany, Poland, and the U.S.S.R.

K. K. L.

**SPHENE** [sfi′n], formerly called titanite, is calcium titanosilicate, $CaTiSiO_5$. The name comes from the Greek word meaning "wedge," in allusion to the characteristic shape of the monoclinic sphene crystals. This mineral is commonly brown in color, more rarely, oily green. The luster ranges from resinous to brilliant. Sphene occurs as a microscopic accessory mineral in different types of igneous rocks, and in larger crystals in pegmatites. It is mined on the Kola Peninsula, U.S.S.R., as an ore of titanium. K. K. L.

**SPHENOPSIDA.** *See* Plant Systematics.

**SPHERICAL TRIGONOMETRY.** *See* Trigonometry.

**SPHEUOPSIDA.** *See* Horsetail; Plant Systematics.

**SPHINX** [sfɪ′ŋks], in ancient Egypt, the stone figure of a lion in a recumbent attitude, the upper part of the body being that of a human, usually male rather than female. In Egypt, sphinxes appear to have been set up along avenues forming the approaches to temples.

The most celebrated among the Egyptian sphinxes is that of the colossal Great Sphinx at Gizeh guarding the entrance to the Nile Valley. With the exception of the paws, it is constructed of one block of stone. The statue was intended to represent the god Hor-em-khu or Horus, and is believed to antedate the IVth Dynasty, which began about 2700 B.C. In some of the Egyptian sphinxes the upper part of the body was that of a ram, the *Crio*-sphinx, or of a falcon, the *Hieraco*-sphinx.

Both the legend and the figure of the sphinx were probably introduced into Greece from Egypt or Ethiopia, but the figure of the sphinx became somewhat modified in Greek mythology and art. C. W. D.

**SPHINX** (Gr. Σφιγξ, the "Strangler"), in Greek mythology, a winged monster with the body of a lion and the head and breast of a woman. According to the myth, the Sphinx destroyed the passersby from the Greek city of Thebes when they failed to guess her riddle: "What is four-footed in the morning, two-footed at noon, three-footed in the evening?" Oedipus solved the riddle by replying: "Man, who in childhood creeps on hands and knees, in manhood walks erect, and in old age uses a staff." The Sphinx, hearing this, threw herself from a rock and perished, and Oedipus thus became the liberator of Thebes and was made its king. *See also* Oedipus. G. E. D.

**SPHINX MOTH,** or hawk moth, the common names given to any moth of the family Sphingidae. All are heavy-bodied and most are streamlined in shape. The wings are long and narrow, with strong veins, and the antennae are short and densely plumose. These moths are fast flyers, and

are among the few kinds of insects that can fly backwards. The proboscis is long, enabling the moth to suck nectar from deep-seated nectaries, hovering before the flower during the process. This habit of the moth has frequently led to confusion with hummingbirds, especially when seen in poor light. Most of the hawk moths are nocturnal, or fly

COURTESY OF THE AMERICAN MUSEUM OF NATURAL HISTORY

*TOMATO SPHINX MOTH*

at dusk, and many kinds are attracted to light. However, there are day fliers among them, including the clearwings or hummingbird moths, of which *Hemaris thysbe* is a common species. The death's-head moth, the tobacco worm, and the tomato worm all belong to this group. C. H. Cu.

**SPICA** [spai'kə], also designated Alpha (*a*) Virginis, the brightest star (magnitude 1.21) in the constellation Virgo. Its position on the celestial sphere is right ascension, 13 hr. 22 min.; declination, — 10°.9. In color it is blue-white. Its distance is considerably over 100 light-years; its intrinsic luminosity, several hundred times that of the sun. Spica is a spectroscopic binary, or double star, the revolution period of which is four days. *See also* VIRGO. J. H. P.

**SPICEBUSH,** a genus, *Lindera,* of the laurel family having about 60 species in eastern Asia and North America. These plants are aromatic trees or shrubs, some yielding an oil used in perfumery. The name is usually applied to the common spicebush, *L. benzoin,* a graceful, branching shrub growing as high as 15 ft., native to New England and to regions southward and westward. It has delicate clusters of small yellow flowers, appearing in early spring before the leaves, and red fruit ripening in the late summer. It is also known as the benzoin tree. J. C. Wis.

**SPICE ISLANDS.** *See* MOLUCCA.

**SPICES,** a group of pungent or aromatic vegetable substances used chiefly as seasoning and as preservatives. Some of these are clove, cinnamon, pepper, mustard, nutmeg, mace, cumin, caraway, rosemary, basil, thyme, dill, marjoram, allspice, ginger, paprika, cardamon, and many others. Their flavor depends on the volatile oils they contain. *See also* FOOD FLAVORS; FOODS AND COOKERY; *and articles on individual spices.* J. A. Bo.

**SPIDER,** a common animal of the class Arachnida, phylum Arthropoda, related to scorpions, mites, and daddy longlegs. Spiders are well known because of their abundance and because of their web-building instinct. They are mostly small animals, ranging in length from 1/25 in. to over 2 in. in the largest tarantulas; the great bulk of them, however, range from 1/8 in. to 1/2 in. The body is divided into two distinct parts, joined by a narrow pedicel. The front part is the cephalothorax; the hind part, the abdomen. The cephalothorax is covered with a hard shield above, which typically bears eight simple eyes on the front part. In some species the eyes are reduced to six, four, or two, and to none at all in the case of a number of cave species. The relative sizes and arrangement of the eyes vary with the different families. There are six pairs of appendages attached to the cephalothorax: a pair of chelicerae, composed of two segments, a base and a moveable fang, used for grasping prey; a pair of pedipalpi, which ordinarily project out in front as feelers but which in the adult males are modified into secondary reproductive organs for transmitting semen to the females during mating; and four pairs of walking legs, which are made up of seven segments each and bear two or three claws on the end. On the underside, between the

COURTESY OF THE AMERICAN MUSEUM OF NATURAL HISTORY

*GARDEN SPIDER*

bases of the legs, is a hard shield, the sternum. The abdomen is usually soft. It bears the spinnerets, from which the silk is spun; these are usually six in number. The silk is used by the spider in making webs, building retreats, making egg cocoons, laying draglines, and ballooning. Also on the underside of the abdomen are the openings for the reproductive and respiratory organs. Breathing is done by means of spiracles, trachea, tubes, and leaflike book lungs. These thin leaves are amply supplied with blood, and gaseous exchanges take place through their surfaces.

Spiders are numerous, both as regards individuals and species. When the species are all known, the number for the world will undoubtedly exceed 50,000 and may approach 100,000. They live at all latitudes and altitudes where insects occur, and inhabit all important islands as well as the continents. They occupy a great variety of habitats, living

in burrows in the ground; in crevices and under bark of trees; under stones, leaves, or trash on the ground; and in houses and basements, where the abandoned webs frequently collect dust. Their behavior patterns also vary greatly; some build webs for capturing their prey, whereas others hunt without snares. Of the more than sixty recognized families of spiders, only two are the geometrical orb weavers so commonly associated with spiders.

Although nearly all spiders possess poison fangs, which are helpful in subduing their prey, few of them are dangerous to man. Except for the black widow and its close relatives and some of the larger tarantulas, they can be ignored by man from the standpoint of poison. All spiders live on insects and other small animals, which they capture alive and from which they suck only the juices. Most spiders live only one season, completing their life cycle in a single year, though a number live two years, and some, notably the tarantulas, may live five or more years. *See also* BLACK WIDOW SPIDER; GARDEN SPIDERS; GOSSAMER; MYGALOMORPHAE; TARANTULA; TRAP-DOOR SPIDER. W. I.

**SPIDER CRAB,** one of a group of true crabs, the Oxyrrhyncha, most of which are characterized by long, slender legs. The typical spider crabs, and by far the greatest number of species of the group, belong to the family Majidae. Some of them are among the slowest moving of Crustacea, depending in many cases upon their camouflaging habits to avoid capture. Bits of seaweed and sedentary animals such as sponges and alcyonarians are snipped off with the claws and carefully placed upon the crab's back, where they are held in place by means of regularly placed hooked hairs. Since these "decorator crabs," as they are sometimes called, seem able to choose marine organisms which will flourish after transplanting in this manner, they are soon effectively concealed beneath a portable garden which blends into the general surroundings. The largest of Crustacea, the giant crab of Japan which may span more than 12 ft., is also a spider crab but does not camouflage itself. Many tropical species, on the other hand, are less than 1 in. across the back. F. A. C.

**SPIDERFLOWER,** the common name of a genus, *Cleome,* of the caper family, having about 30 species widely found, usually in tropical regions. Spiderflowers are chiefly

*THE SPIDERFLOWER* (CLEOME SPINOSA)

annual herbs, some of which are shrubby species, often strong-scented, and sticky to the touch. Some are cultivated as ornaments, especially the spiny spiderflower, *C. spinosa,* which grows as high as 4 ft. and has long, flowering stalks bearing rose-purple or white flowers which have conspicuously long stamens. Various good garden varieties have been introduced. J. C. Wis.

**SPIDER LILY,** a group of plants in the genus *Hymenocallis,* of the amaryllis family, native to southern United States and tropical America. The large terminal flowers,

COURTESY OF THE NEW YORK BOTANICAL GARDENS

*SPIDER LILY, HYMENOCALLIS*

which occur either singly or in clusters at the summit of a solid scape, rise directly from the bulb. The showy flowers are white, pink, or purplish. The segments of the perianth are reflexed and exceedingly narrow, and the long filaments of the stamens are united at the base into a cup-like crown. Several species are in cultivation as greenhouse plants, or as outdoor specimens in warm climates. They flower in spring or summer, and are long-lived. C. H. Wo.

**SPIDER MONKEY,** the most typically arboreal of the American monkey, *Ateles,* known locally as coaitas. They are less active in the trees than the gibbons and some Old World monkeys, but they are especially adapted to tree life. The tail is long, as much as three times the length of the trunk, prehensile, and naked along the underface of the tip. The arms and legs are greatly elongated, as the name suggests. The thumb is so short as to be nonfunctional, the hand being used as a hook in swinging through the trees. The body is slender, and has a small, prominent belly. The head is small and round; the eyes large and expressive; the hairy covering coarse and straight, not woolly. Most of the hair of the head is directed forward.

The tail of this monkey serves as a fifth hand, being used to feel for a branch to grasp, or to draw objects within reach of the hand. When not in use, the tail is carried erect or over the back.

Spider monkeys travel in bands of twenty to thirty through the forest canopy. They have been known to band with capuchin monkeys. They are silent monkeys, but when dis-

turbed will sometimes hurl branches and fruit at men on the ground. Their food consists of fruit and leaves. They make good pets; the mobility of their facial muscles and their quiet

*SPIDER MONKEY*

gymnastics lend an interest lacking in many other monkeys. In most parts of their range, they are esteemed as food.
R. T. H.

**SPIDERWORT,** a genus, *Tradescantia,* of the spiderwort family, of which about 35 species are scattered from Manitoba to Argentina, and about 15 grow in the United States. These plants are soft, succulent, perennial herbs. They have narrow, alternate leaves, and red, blue, or white flowers, usually in clusters. The Virginia spiderwort, *T. virginiana,* has narrow basal leaves and a flower stalk 1 to 3 ft. high, which bears a long succession of violet-blue flowers, often 1 to 2 in. in diameter. *See also* WANDERING JEW.
J. C. Wis.

**SPIKE GRASS,** a common name for several species of the grass family which bear rather conspicuous flowering spikes. Among them are *Leptochloa fascicularis, Distichlis spicata, Triglochin maritima,* and several species of *Uniola,* all found in North America, chiefly in coastal, marshy, and alkaline locations. *See also* ALKALI GRASS; SALT GRASS.
J. C. Wis.

**SPIKENARD** [spai′knərd; spai′knɑrd], a perennial Himalayan herb, *Nardostachys jatamansi,* of the valerian family. Its fragrant, musky rootstocks, or spikes, used in perfumery and ointments, are considered the source of the costly spikenard of biblical times. Several other plants are known locally as spikenard. American spikenard, *Aralia racemosa,* of the ginseng family, a woodland herb of eastern North America having spicy aromatic roots, was used by the Indians, medicinally and in beverages. J. C. Wis.

**SPINACH,** *Spinacia oleracea,* an annual of the goosefoot family, cultivated for its edible leaves. It is probably native to southwestern Asia. The shrub, to 2 ft. in height, bears large leaves growing in a cluster from the root. The small flowers are in axillary clusters and are followed by spiny capsulelike fruits containing the seeds. Spinach is essentially a cool-season crop, and is grown both as a spring and fall crop. The plant is of easy cultivation, growing in a well-drained and limed soil. Several varieties exist, including the round-seeded spinach, *S. oleracea* var. *inermis.* V. A. T.

**SPINAL CORD.** *See* COMPARATIVE ANATOMY; NERVOUS SYSTEM.

**SPINDLE TREE,** also called burning bush or strawberry bush, a genus, *Euonymus,* of the staff-tree family, which occurs in about 120 species, chiefly in the Northern Hemisphere, 6 of which are found in North America. They are deciduous, rarely evergreen shrubs or vines, with opposite leaves, usually brilliantly colored in the autumn, and with inconspicuous flowers and bright fruits. In Europe, the wood, which is tough and close-grained, is used for the manufacture of small tools and for other such purposes. The bark of the American species has medicinal properties. Because of the spindle tree's handsome foliage and fruits, many of the more hardy Asiatic species are used as ornamentals. The winged euonymus, *E. alatus,* a deciduous spreading shrub reaching a height of 8 ft., has corky wings on the twigs, small leaves, and purplish-red autumn foliage. *E. japonicus,* an upright shrub growing as high as 15 ft., is evergreen. *E. fortunei radicans,* native to Japan, is an evergreen climbing shrub growing to 20 ft. *E. americanus,* an upright shrub to 8 ft., is found from New York to Texas, and has brilliant pink fruits. J. C. Wis.

**SPINE** or **SPINAL COLUMN.** *See* MAN, FUNCTIONAL ANATOMY OF.

**SPINEL** [spinɛ′l], a mineral that is most commonly composed of magnesium, aluminum, and oxygen, $MgH_2O_4$. However, manganese, iron (both ferrous and ferric), and chromium may replace a part at least of the magnesium and aluminum. Spinel always crystallizes in octahedrons. Its hardness (8) is greater than that of any other octahedral mineral except diamond. The typical occurrence of spinel is as a contact metamorphic mineral, especially in magnesian limestones. It may also be an accessory mineral in basic igneous rocks. Spinel has no value except as a gem.

**Gems.** This mineral is often found in association with ruby and sapphire and is usually ruby-red or pink, but blue, green, brown, yellow, and even black spinels have been found. The gravel deposits of Ceylon yield fine specimens; other sources are Burma, Siam, Sweden, and Franklin County, New Jersey. Pleonaste, ceylonite, balas, gahno, and chloro are names that have been applied to varieties of this stone. This gem has often been confused with the true ruby. Two famous gems of history, the Black Prince ruby and the Timur ruby, are now known to be spinels. Gem spinel occurs in large sizes up to three hundred carats.

**Synthetic Spinel.** Spinel has been successfully reproduced by man. Synthetic spinel is manufactured in the same manner as synthetic ruby and sapphire. These gems are usually made in two colors—sapphire blue and aquamarine blue-green. Synthetic spinel has a slightly greater density and a higher index of refraction. The synthetic product has pronounced fluorescence when activated by X-ray radiation.

Genuine spinel may reveal no fluorescence or only a trace, when similarly tested. K. K. L.

**SPINET** [spɪ′nət], a musical instrument of the fifteenth to eighteenth centuries, identical in principle with the harpsichord (with which spinet was originally synonymous) but usually smaller, and rectangular in form rather than wing-

COURTESY OF WM. KNABE & COMPANY

*A SPINET OF MODERN DESIGN*

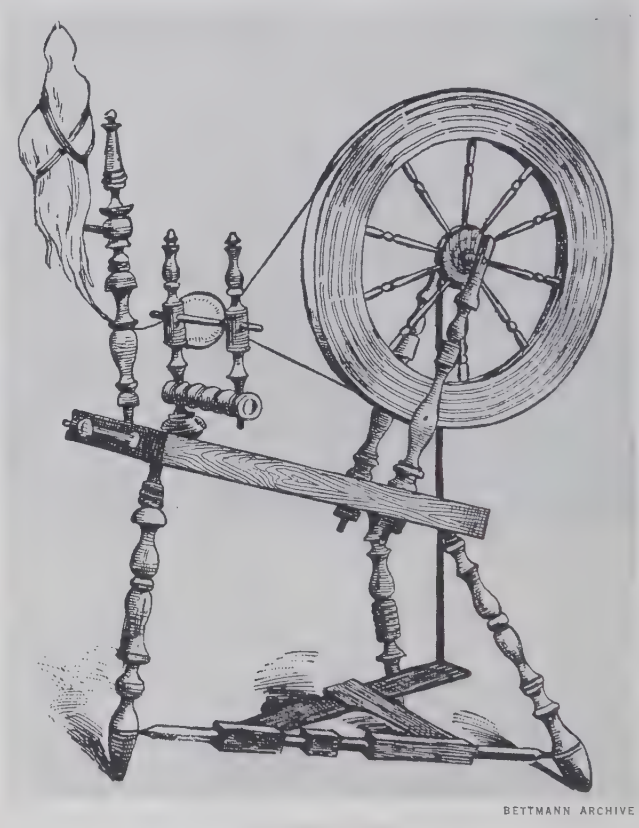
shaped. In modern piano-trade parlance, small, oblong pianos are sometimes called spinets in contrast to larger, heavier, wing-shaped grand pianos. *See also* HARPSICHORD. W. Li.

**SPINNING.** Spinning is a process by which fiber lengths are simultaneously overlapped and spiraled to gain length and strength. The principle is the same, from the crude cordages of the Stone Age down to the finest threads from modern machines. Twine and rope as binders made possible many advances of civilization—e.g., lashings on weapons and tools (for subsistence, defense, construction), hauling and hoisting heavy objects (stone architecture), lashings and fastenings on sailing ships (trade, exploration). Spun yarns are basic ingredients of the warm and cool clothing which permitted man to settle in varied, difficult climates.

The simplest method is thigh-spinning, whereby fibers are rolled down the right thigh under the right hand as they are fed in by the left. Some primitive peoples still use this method; ancient Egyptians substituted a thigh-shaped stone, while Greeks placed a curved tile over the knee.

The spindle is a short, pointed stick with a disc weight (whorl) as a flywheel. Fibers are drawn from stock in the left hand, slightly twisted to form a loose yarn (roving). The free end of the roving is wound on the spindle shaft, spiraling off its upper tip. The spindle is then twirled by the right hand and allowed to swing free. The whorl gives momentum and pulls down on the twisting fibers (drop-spindle spinning). A distaff held under the left arm may carry the stock of fibers, permitting the left hand more freedom to draw out new fibers. When a length of yarn is formed it is wound up on the spindle shaft (spooling), and the cycle of action is repeated. For delicate threads which could not sustain the swinging weight, the spindle is twirled with its lower tip resting on the ground or in a bowl (supported-spindle spinning). The spindle was in use 10,000 years ago; Egyptians made linen thread with the drop-spindle; in India supported-spindle spinning produced fragile cotton threads.

The simplest form of the spinning wheel is a plank on which a spindle is set horizontally in a revolving cylinder motivated by a belt around a large, hand-cranked wheel. The spinner feeds fibers to the spindle tip with the left hand while cranking with the right. When an arm's length of yarn is formed it is spooled on the spindle shaft, and the action-cycle repeated. Speed and control are gained, but spinning must stop for spooling. This device probably originated in India and diffused east and west; it was used in Europe by the early fourteenth century and continues in India and Indonesia for spinning cotton and wild silk.



BETTMANN ARCHIVE

*A SPINNING WHEEL*

Spinning and spooling were made simultaneous by a fifteenth century improvement, the addition of a flyer. The spindle shaft now serves as an axle on which are mounted a spool and the flyer. The flyer is U-shaped, its two arms extending beyond the spool. The roving to be spun passes through an eye in the spindle tip, over a hook on the flyer arm, and down to the spool. Spool and flyer have separate belts coming from the drivewheel, their pulleys of different diameters causing the flyer to revolve faster than the spool. When put in motion, the whirling flyer twists the roving into yarn while it moves on to the slower-turning spool. The addition of a treadle in the sixteenth century freed the right hand, the drivewheel now being propelled by footpower. A distaff set into the base plank brought stock fiber within the spinner's reach. This combination, mounted on a variety of frames but retaining the essential spindle, flyer, spool, distaff, and treadle, is the heritage of our "Colonial" spinning wheel.

Desire for quantity, uniformity, and speed in production

led to the development of machines with multiple spindles and spools. Leonardo da Vinci devised a hand-cranked machine with several spindles and uniform spooling flyers (c. 1490). Improvements in mass-production spinning machines were made in the eighteenth century, notably by James Hargreaves and Richard Arkwright, from which derive the mechanical procedures of modern spinning mills.

A. H. G.

**SPINOZA, BARUCH** or **BENEDICT DE** [spino'zə] (1632-1677), Dutch philosopher, was born Nov. 24, 1632, in Amsterdam. His parents were Jewish emigrants from the Iberian Peninsula, and he was brought up in the Orthodox Jewish religion. He was, however, excommunicated by the Jewish community in 1656 for his heretical views, and in 1660 he removed for some years to Rijnsburg, near Leiden, in association with members of the sect of Collegiants. From Rijnsburg he went to Voorburg near The Hague, and from 1670 till the time of his death on Feb. 21, 1677, he lived in The Hague itself. He made his living grinding and polishing lenses for the newly invented microscope and telescope, and in later years his income was supplemented by a small pension from two of his influential friends. This arrangement assured his independence and left him sufficient time to pursue his philosophical writing and correspondence with the leading scientists of his day. In 1673 he was offered the chair of philosophy at Heidelberg, but he refused it in view of the known hostility of the clergy to his views. His chief works are his *Tractatus Theologico-Politicus,* published anonymously in 1670, and his *Ethics,* completed in 1675, but published posthumously in 1677 in a Latin edition together with his unfinished treatises on scientific method, political theory, and Hebrew grammar.

Spinoza's contribution to the history of philosophical thought was determined, in part, by his position in time at the beginning of the modern era. It consists in his synthesis of Renaissance science with Greek, Stoic, Neo-platonic, and Scholastic philosophy. One reason for the difficulty scholars have found in interpreting his most famous work, the *Ethics,* is to be found in the fact that he frequently employs Scholastic terms in an entirely new sense. As a result, one must go behind his terminology and take his essentially modern, scientific, and ontological presuppositions into account in order to arrive at his real meaning.

Spinoza's basic interest may be regarded as philosophical anthropology, the study of man in relation to society and to the cosmos as a whole. The originality of his contribution lies in his attempt to extend the "Copernican revolution," initiated in astronomy, to the spheres of metaphysics, psychology, ethics, and politics. In other words, he attempted to view nature in general, and human nature in particular, objectively and scientifically, just as if he were dealing impersonally with a problem in geometry; he made a sustained effort to exclude, so far as possible, human wishful thinking such as is presupposed by the notion of ends or final causes in nature. Thus, in agreement with the Italian Renaissance philosopher Giordano Bruno, he was among the first to view the cosmos as infinite rather than as a finite system, and to accept the heliocentric hypothesis rather than the geocentric tradition of the Scholastics. He viewed man as part of the order of nature and not as a special creation exempt from its universal laws. God was conceived by him as the dynamic principle of order immanent within nature as a whole (*natura naturans*), as against the traditional notion of God as the transcendent creator of the order of nature. As the dynamic principle of order within nature, the God of Spinoza was essentially the impersonal God of the scientist, a God who may be conceived as the object of "intellectual love," but who, unlike the God of the Old Testament, did not reciprocate man's love and had no special concern with the welfare of individuals.

Building upon Descartes' dualistic theory of the relation of body and mind, Spinoza originated the theory of the parallelism of body and mind, the theory that the mind, like the body, is subject to determinate laws of activity. Spinoza thus provided the basis for the modern science of psychology. He considered the mind as a "spiritual automaton" subject to necessary laws of its own, just as the body was subject to the laws of motion, as Descartes had demonstrated. Furthermore, Spinoza, like Thomas Hobbes, was among the first of the Renaissance philosophers to apply Galileo's law of inertia to psychology and ethics, by postulating that by nature every form of life endeavors to persevere in existence indefinitely unless it is hindered from doing so by some superior force. The notion of the primacy of the endeavor (*conatus*) for self-preservation—later developed by Charles Darwin from an evolutionary, biological point of view—marked a complete departure from the theory of the Scholastic philosophers, who held that all forms of nature were directed to fixed ends or final causes and that human nature existed for the sake of some transcendent, supernatural end. In his *Ethics* Spinoza endeavored to construct a psychology of the emotions in which the emotions were considered as dynamic forces subject to determinate laws—laws that may be logically deduced from the nature of the three primary affects or emotions, namely, pleasure, pain, and desire. The notion that there is a logic of the emotions, and that the emotions are not merely irrational forces or diseases which have somehow to be suppressed or eliminated, is one that was scarcely appreciated in Spinoza's time. It is only in recent years, through the advent and recognition of Freudian psychiatry, that it is beginning to be recognized.

*BARUCH SPINOZA*

COURTESY OF THE NEW YORK PUBLIC LIBRARY

In moral theory, Spinoza's originality was manifested by his transvaluation of traditional moral values—a fact which Friedrich Nietzsche later recognized—and by his interpretation of human virtue in terms of the efficient power of the individual. Spinoza's moral theory is naturalistic and of this world; it is opposed to the transcendental religious view that life on earth is but a preparation for life after death. Not grief and a sense of sin or guilt but joy and peace of mind are the leading motifs of his philosophy of life. Throughout his psychology and ethics the basic underlying theme is the humanistic one that human nature, as Francis Bacon said of nature as a whole, must first be understood and obeyed before it may be commanded and controlled.

In Spinoza's thought ethics and religion are blended. His philosophy of life is the classic attempt of modern times to construct a rational, universal system of human salvation which may dispense with supernatural sanctions and avoid any special appeal to historical revelations—an approach which has made it especially attractive to men of science like Albert Einstein, poets like Goethe and Wordsworth who sought communion with nature, and liberals generally who sought for some way of escaping the intolerance of dogmatic theology. D. B.

**SPINY ANTEATER.** *See* ECHIDNA.

**SPIRAEA** [spairi'ə], a genus of the rose family, of which about 75 species are native to the Northern Hemisphere, and about 12 to the United States. These plants are usually hardy shrubs, seldom more than 5 ft. high. They have rather small leaves, often lobed, and small white or pink flowers borne in conspicuous clusters. Those species having white flowers in flat clusters usually bloom from April to June; others, having white or pink flowers in spikes, usually bloom after June. Many are grown as ornamentals, including *S. thunbergii, S. Veitchii,* and the very popular *S. vanhouttei. See also* HARDHACK; MEADOWSWEET. J. C. Wis.

**SPIRES.** *See* SPEYER or SPIRES.

**SPIRITUALS,** in ecclesiastical history, the name given, probably by the common people, to several groups of Friars Minor of the late thirteenth and early fourteenth centuries. Opposed to necessary modifications in Franciscan life which were approved by the popes to enable the friars to settle in towns and attend universities, these groups sought authorized separation from the order on the plea that they wished to observe St. Francis' rule literally in its pristine severity. Three groups are to be distinguished. (1) The Spirituals of the Marches of Ancona (Italy), who separated from the Franciscan order about 1274, were excommunicated by John XXII in 1317. (2) The Spirituals of Provence (France), led by Peter John Olivi, certain of whose errors were condemned in 1312, were ordered by John XXII in 1317 to submit to Franciscan superiors. Twenty-five refused, of whom twenty-one were converted by the inquisitor, and four were burned as heretics at Marseilles in 1318. (3) The Spirituals of Tuscany, who separated in 1309, fled to Sicily and were excommunicated in 1318. *See also* FRATICELLI. W. C.

**SPIROCHETES** [spai'rokits] (Gr. σπεῖρα, coil, and χαίτη, hair), members of the order Spirochaetales, of the class Schizomycetes which consists of unicellular, frequently motile plants without a definite, organized nucleus. Spirochetes used to be regarded as Protozoa, but are now classified as Bacteria. They multiply by transverse fission and show no evidence of any sexual cycle. In mode of life, spirochetes may be free-living, commensal, pathogenic, or parasitic. The order includes two families, Spirochaetaceae and Treponemataceae.

**Nonpathogenic Spirochetes.** Members of the Spirochaetaceae family have cells with definite protoplasmic structure and are largely saprophytic or free-living, inhabiting water, sewage, and other organic wastes. Representatives of the true genus *Spirochaeta,* found in stagnant waters, are fairly long, ranging from 200 to 500 microns, and have a central axis, around which the body is wound. The protoplasm contains vacuoles and deep-staining granules. Members of the free-living genus *Saprospira,* found in fresh and salt waters and in oysters, are also fairly long, ranging up to 100 microns. They have rigid, undulating coils and lack crista, or ridges. Such ridges are characteristic of *Cristispira,* found in certain molluscs. *Cristispira* range from 45 to 100 microns in length, and are cylindrical, with short inner segments and coarse spirals.

**Pathogenic Spirochetes.** Most of the family Treponemataceae are parasitic, and many of them are pathogenic for man or animals. The family includes three genera: *Borrelia, Treponema,* and *Leptospira.*

*Borrelia* have the shape of delicate, spiral filaments, 10 to 20 microns long, with fairly regular coils. They can be cultivated in a laboratory and stain readily with aniline dyes but are best seen under a dark-field microscope. Some *Borrelia* species are saprophytic and apparently harmless. *B. vincentii,* together with some fusiform bacilli, is responsible for the ulcerative disease of the mouth, known as Vincent's angina. *B. recurrentis,* in Europe, and *B. duttoni,* in Africa, carried by lice and ticks, respectively, are the causative factors of relapsing fever.

By far the most dreaded genus of spirochetes is *Treponema,* a strictly anaerobic and parasitic form, difficult to stain and to culture. *T. pallidum* is the causative agent of syphilis. It is a delicate, spiral organism, 5 to 15 microns in length, highly flexible and motile. It is best seen under a dark-field microscope. *T. pertenue,* morphologically indistinguishable from *T. pallidum,* causes yaws. Some other *Treponema* species are pathogenic for man and animals; others, often present in the mouth, are apparently harmless.

The genus *Leptospira* is represented by small, slender organisms, 6 to 9 microns long, with fine, closely wound coils, often hooked at both ends. It is aerobic and can be grown in laboratory cultures. *L. icterohaemorrhagiae* is responsible for infectious jaundice. Diseases caused by this genus are localized primarily in the liver and kidneys. Other *Leptospira* species produce several varieties of febrile diseases in man and animals. *See also* RELAPSING FEVER; VENEREAL DISEASES; YAWS. B. Van R.

**SPITHEAD** [spɪ'thɛd'], a roadstead at the entrance to Portsmouth Harbor, Hampshire, England. It extends for 2 mi. in a north-south direction along the southwestern side of the Spit Sand, with an average width of one-half mile. S. Van V.

**SPITTELER, CARL** [shpɪ'tələr] (1845-1924), Swiss poet and novelist, was born April 24, 1845, at Liestal, Canton Basel-Land. At Basel he studied law, then theology, and continued his studies at Zürich and Heidelberg. A break with theological concepts forced him to become a teacher, first as a private tutor in Russia and Finland (1871-1879) and, upon returning to Switzerland, in schools at Bern and Neuenstadt. In 1885 he became literary editor of a Basel newspaper, and in 1890 of the *Neuen Züricher Zeitung.* An inheritance in 1892 enabled him to devote himself exclusively to his writings, and he moved to Luzern, where he lived until his death, Dec. 29, 1924.

Although primarily an epic poet, Spitteler is stylistically and spiritually related to the lyric Impressionists. The principal theme of his most significant works is the contrast between the superior man and the uncomprehending hostile masses. The superior man, the virile, aristocratic type, is represented by Prometheus in the prose epic, *Prometheus und Epimetheus* (1880-1881), a work strikingly akin, both in form and spirit, to Nietzsche's later *Also sprach Zarathustra* (1883-1885). In the great "cosmic" (i.e., transcending the human realm) epic, *Olympischer Frühling* ("Olym-

pian Spring"; 4 vol., 1900-1905), Hercules becomes the savior of mankind. The cosmic and heroic element also prevails in *Extramundana* (1882), a collection of short epics, and in the *Balladen* (1895). Shortly before his death Spitteler returned to his Prometheus theme, recasting his first work freely into rhyming hexameters: *Prometheus der Dulder* ("Prometheus the Long-Suffering," 1924). The contrast between the artist and the masses is shown in the psychoanalytic novel, *Imago* (1906).

In his prose narratives, *Die Mädchenfeinde* ("The Little Misogynists," 1891), *Conrad der Leutnant* ("Conrad the Lieutenant," 1898), and the autobiographical *Meine Frühesten Erlebnisse* ("My Earliest Experiences," 1914), Spitteler approaches the tradition of the realistic Swiss *Novelle*; and timely literary criticism is found in the collection of essays, *Lachende Wahrheiten* ("Laughing Truths," 1898). His best lyrics are found in the collections *Schmetterlinge* ("Butterflies," 1888) and *Glockenlieder* ("Bell Songs," 1906). In 1919, he was awarded the Nobel Prize for literature.

K.-H. P.

**SPITTLE INSECT,** a name given to both the nymphs and the adult members of the family Cercopidae, of the order Homoptera. The adults are also known as froghoppers, and in some parts of America the nymphs are called cuckoo spit insects. Eggs of the spittle insects are usually laid in the stems of grasses or on the bark of twigs. When the nymph hatches, it sucks the juices of the host plant and almost at once gives forth a frothy secretion, which increases in volume as the insect grows. Within this mass, which resembles the frothy saliva produced by man, the nymph is protected from its enemies, and grows to maturity. It then crawls from the spittle, and emerges as an adult hopping bug. Sometimes spittle insects are so numerous that grass and twigs are heavily spotted with their froth; they can cause serious damage to grasses and shrubs. They vary in size from ⅛ to ½ in. Most species, however, are about ¼ in. long. The sugarcane froghopper causes serious damage to sugar cane in Trinidad.

**SPITZBERGEN.** *See* Svalbard.

**SPITZER, LEO** [shpɪ'tsər] (1887- ), Austrian linguist, was born in Vienna on Feb. 7, 1887. He began his teaching career at the University of Vienna in 1913, and after holding professorships at Bonn, Marburg, Cologne, and Istanbul, he went to the United States in 1936. As professor of linguistics at Johns Hopkins University at Baltimore, Md., he has trained a notable body of scholars.

A follower of Benedetto Croce and Karl Vossler, Spitzer is one of the foremost champions of the idealistic method in the study of language. Surpassing both Croce and Vossler in linguistic technique, he couples a daring vision with an enormous fund of knowledge and a scrupulous attention to details. His abiding interest lies in discovering the aesthetic motive that underlies linguistic expressions and changes, or, as he calls it, the "stylistic" of language.

Being essentially an individualist, Spitzer seeks the key to the understanding of language in the passing whims, fancies, and conceptions of the individual, and his first work deals with the language of an exceptionally fantastic and creative author, Rabelais (*Die Wortbildung als stilistisches Mittel, exemplifiziert an Rabelais,* 1910). He has also studied the styles of Henri Barbusse, Jules Romains, Charles Péguy, and Marcel Proust. Spitzer has done important work in phononology, morphology, and syntax, but the branch of linguistics that has attracted him most is etymology, which deals, especially in such manifestations as onomatopoeia and sound symbolism, with the impulsive, spontaneous creations of the individual.

Of the vast body of Spitzer's publications, the following may be mentioned: *Aufsätze zur romanischen Syntax und Stilistik* (1918), *Lexikalisches aus dem Katalanischen und den übrigen ibero-romanischen Sprachen* (1921), *Italienische Umgangssprache* (1922), *Stilstudien* (1928), *Classical and Christian Ideas of World Harmony* (1944), *Linguistics and Literary Semantics* (1948), and *A Method of Interpreting Literature* (1949).

G. B.

**SPLEEN,** an oval, flattened, glandlike organ, situated in the left upper part of the abdominal cavity. It is not essential to life and its congenital absence or surgical removal has no marked effect on normal life and growth.

**Anatomy.** The spleen is composed of several types of tissues. Embryologically, it is of mesodermal origin. Some of the primitive mesenchymal cells persist through life, while others develop into reticulo-endothelial and lymphoid cells. The splenic pulp consists largely of the former, while the lymphoid cells are found in the Malpighian corpuscles. The spleen is highly vascularized and is of a dull purple color. In addition to the serous peritoneal cover, it is covered by a capsule of dense, fibrous, elastic tissue, with bundles of involuntary muscles. Trabeculae pass from the capsule into the spleen, forming a framework for lobules. The spleen is the largest lymphoid organ in the body. It has direct connection with both the portal and the general circulations. It is still unsettled whether the spleen circulation is a closed or an open system.

**Physiology.** Galen regarded the spleen as an organ "full of mystery." Ancient Greeks and Romans reportedly removed the spleens of runners to increase their speed. The functions of the spleen are still incompletely known. For a long time, it was regarded as a ductless gland; since there is no apparent secretion, this view had been abandoned. Recently, the theory has been revived to some extent, attributing to the spleen a hormonal action that regulates the function of the bone marrow.

In early fetal life, the spleen has a hematopoietic function. By the ninth month, formation of red blood cells and of granulocytic white cells is taken over by the bone marrow, while the spleen from then on produces only lymphocytes and monocytes. In certain blood diseases, however, the spleen reverts to this embryonal function, and in some mammals it maintains this function throughout life.

In the human adult, the known functions of the spleen are threefold. As part of the reticulo-endothelial system, it has the important task of phagocytizing the worn-out red and white blood cells and blood platelets, as well as of breaking down hemoglobin into bilirubin and hemosiderin. The spleen is one of the richest iron reservoirs in the body. It also acts as a filter of bacteria, protozoa, and foreign particles. As a lymphoid organ, the spleen is the chief formative source of circulating lymphocytes, especially in youth and early adult life. As a circulatory organ, the spleen functions as a reservoir of red blood cells, from which they may be withdrawn in case of emergency. It is also possible that the spleen participates in the antibody formation, since splenectomized animals are more susceptible to infection.

**Disorders of the Spleen.** Primary diseases of the spleen are comparatively rare, but secondary involvement is more frequent than in any other organ.

*Abnormalities.* The spleen may be congenitally absent. Deviations in size, shape, and structure, such as excessive

lobulation, are also possible. Accessory spleens, sometimes in considerable numbers, are fairly common. Floating or wandering spleen occurs more frequently in women.

*Infarcts.* Infarction of the spleen vessels is fairly common. The infarcts are usually small.

*Torsion.* The pedicle of the spleen may become twisted, resulting in strangulation, and requiring surgery.

*Abscesses.* Abscesses of the spleen are sometimes caused by infarction and are also seen in enteric fever and in subacute bacterial endocarditis. They are usually chronic and painless and tend to heal spontaneously.

*Cysts.* The spleen is also subject to formation of dermoid and echinococcal cysts, which are extremely rare, and of serous cysts, which are more common. These, as well as rupture of the spleen, are usually the result of trauma.

*Degenerative and Neoplastic Diseases.* Amyloid degeneration, produced by chronic tuberculosis or chronic osteomyelitis, results in the so called "sago" spleen. Incidence of amyloid degeneration is becoming progressively lower. Atrophy of the spleen is common in old age and may also occur in sickle-cell anemia.

Primary malignant tumors of the spleen are rare; the typical neoplasm is lymphosarcoma. Metastatic involvement is somewhat more common.

*Splenomegaly.* Splenomegaly, or enlargement of the spleen, is the characteristic response of this organ to numerous systemic diseases. It may be associated with lymph-node enlargement, ascites, jaundice, leukopenia, fever, liver enlargement, and severe anemia. Splenomegaly is seen in many cardiovascular disorders; in such infectious diseases as malaria, typhoid fever, rheumatic fever, smallpox, measles, syphilis, meningitis, scarlet fever, etc.; and in blood dyscrasias such as leukemia, hemolytic jaundice, sickle-cell anemia, pernicious anemia, etc. In Hodgkin's disease, splenomegaly occurs occasionally, but in myelogenic leukemia the spleen becomes enormous. Metabolic disturbances, particularly of the lipid metabolism, are often accompanied by splenomegaly. Many diseases of the liver are reflected in the spleen. This is particularly pronounced in Banti's syndrome, in which cirrhosis of the liver is accompanied by splenomegaly and anemia. Gaucher's diseases, a familial malady, is manifested by inherited disorder of fat metabolism and marked splenomegaly.

Since splenomegaly is usually a reflection of some other disease, the treatment must be directed at the primary causative factor. Removal of the spleen is recommended only in certain conditions, such as hemolytic jaundice, thrombocytopenic purpura, or Banti's syndrome. B. Van R.

**SPLEENWORT,** a name for the large genus, *Asplenium,* of beautiful, mostly evergreen ferns of the true fern family. The several hundred species are found throughout the world. About 25 species are native in North America, mostly in the eastern and southern United States. Among the best known are three small ferns: the ebony spleenwort, *A. platyneuron,* having fronds 15 in. long; the maidenhair spleenwort, *A. trichomanes,* which makes tufts a few inches across in walls and cliffs; and the wall rue spleenwort, *A. ruta-muraria,* found in limestone cliffs, the fronds of which reach only 3 in. in length. Many tropical species are in cultivation, including the *A. nidus* of Asia. G. M. Sm.

**SPLIT** [spli't] (Ital. Spalato), the chief seaport of Yugoslavia, on the Dalmatian coast about 160 airline miles southeast of Rijeka (Fiume). Now a city in Bosnia-Hercegovina, Yugoslavia, Split was the capital of the former province of Dalmatia. It occupies a low peninsula on the rugged Dalmatian coast and is separated from the open Adriatic by numerous intervening islands.

Built in and around the palace, constructed by the Roman Emperor Diocletian in A.D. 305 for his declining years after abdicating, Split is near the ancient Greek town of Aspalathos. It was nearly destroyed by Avars in the seventh century of the Christian Era and subsequently came under the successive rules of Venice, Hungary, France, Austria, and Italy; it became Yugoslavian in 1918 and was occupied by Italians from 1941 to 1945, when it was freed by the Yugoslav army of liberation.

The old town (Stari Grad) of Split is a maze of dark, narrow streets within the walls of Diocletian's Palace, where hundreds of shops and thousands of people are crowded together in less than ten acres. The new town (Novi Grad) is modern, with wide streets, imposing buildings, and a beautiful park. The Roman palace and ruins of several castles, an imposing waterfront, and the picturesque homes and gardens of the suburbs, together with striking natural scenery and the fast-disappearing native costumes, combine to make Split a notably attractive city. It has rail connections with Rijeka as well as inland, and excellent port facilities normally handle exports of cement, lumber, bauxite, and cattle. Pop. 1948, 49,885. F. Sc.

**SPODUMENE** [spɒ'jumin], a lithium mineral usually classified in the pyroxene group. It is lithium aluminum silicate, $LiAlSi_2O_6$. The crystallization is monoclinic and prismatic; some crystals have been found up to forty feet in length. Spodumene is usually white or gray, and has perfect cleavage parallel to the prism faces and meeting at angles of 87° and 93°. A parting parallel to the front pinacoid may also be present. Spodumene turns the fusing flame red due to its lithium content. This mineral is mined as an ore of lithium in the Black Hills of South Dakota and in North Carolina. K. K. L.

**SPOHR, LUDWIG** [shpɔ'r] (1784-1859), German violinist, composer, and conductor, was born on Apr. 5, 1784, in Brunswick. He was a favorite among early German Romantic composers, but the great popularity enjoyed by his compositions during his lifetime was soon lost by all but the violin concertos. Spohr was a violinist and conductor of great ability. He was among the first to use a baton in conducting an orchestra, instead of the violin bow of the earlier concert masters. His works include operas, symphonies, violin concertos, oratorios, chamber music, and a violin method. Spohr died in Kassel, Oct. 22, 1859. E. L. F.

**SPOKANE.** *See* INDIAN TRIBES, NORTH AMERICAN (*Plateau*).

**SPOKANE** [spokæ'n], a city in eastern Washington, the county seat of Spokane Co. It is situated about halfway between the north and south borders of the state, 20 mi. west of the Idaho border, on the falls of the Spokane River, at an altitude of 1,981 ft., 30 mi. west of Coeur d'Alene, Idaho, and 115 mi. northeast of Walla Walla. Spokane is a distributing point for the surrounding fertile agricultural and stock-raising district. The city lies in the richest white-pine section of the United States; and lead, zinc, and silver also are natural resources of the region. Spokane is the financial and commercial center of the great western area known as the Inland Empire, which encompasses eastern Washington, western Montana and Idaho, northeastern Oregon, and

southern British Columbia. In 1810 the Northwest Fur Company established a settlement on the site, but it did not last. Spokane was founded about 1872 by James Glover. It was incorporated as a town in 1878 and as a city in 1881; the following year it was made the county seat. For some time it was known as Spokane Falls. The city is governed by a commission. Transportation is provided by the Great Northern, the Northern Pacific, the Union Pacific, the Spokane International, the Spokane, Portland and Seattle, and the Chicago, Milwaukee, St. Paul and Pacific railroads, and by the Northwest, the United, and the Empire air lines. The industrial output includes lumber and lumber products, aluminum, magnesium, cement and clay products, poultry, dairy and meat products, machinery and metal products, petroleum products, electrical fixtures, beer, paper, cereals, feed, and flour. Pop. 1950, 161,721.

**SPOLETO** [spole'to], an Italian city in Umbria, at the head of the valley of the Maroggia, on the Tessino River, a tributary of the upper Tevere (Tiber), 60 mi. northeast of Rome. Spoleto rests on the slopes of Monte Luco, at between 950 and 1,400 ft. above sea level.

Spoleto was a city of the Umbri before becoming an Etruscan center. It was taken by Rome in 241 B.C., during the Third Samnite War, and in 217 it repulsed Hannibal. After the fall of the Western Empire, the Goths, and later the Byzantines under Narses, took Spoleto. In the latter part of the sixth century the Lombards came down from the north and established the Duchy of Spoleto. Although this did not endure so long as the Lombard Duchy of Benevento, it preserved its autonomy until around 758, when it accepted the king of the Franks and the Pope as nominal overlords. Early in the thirteenth century the Holy See fully annexed the Spoletan territory, which formed part of the Papal States until 1860, when Umbria voted to join the Kingdom of Sardinia, later (1861) the Kingdom of Italy. During the late Middle Ages Spoleto was involved in the struggles between the Umbrian cities and between the Guelfs and the Ghibellines. More than once it rebelled against Papal rule, and in 1499 it was governed by Lucrezia Borgia.

Spoleto has a medieval appearance, with narrow, winding, and often steep streets, and a great number of Renaissance buildings. Several important remains attest to its importance in Roman times: a theatre, a triumphal arch dedicated to Drusus and Germanicus, a now subterranean bridge, and the house of Vespasian's mother, among others. Among the noteworthy churches are the Cathedral (consecrated in 1067 and containing frescoes by Filippo Lippi), Santi Giovanni e Paolo (with frescoes of the eleventh century), San Pietro (begun in the fifth century), and Il Crocifisso or San Salvatore (a basilica of the fourth century). Overlooking the town is the castle of La Rocca, constructed in the fourteenth century and completed by Pope Nicholas V in the middle of the fifteenth century. This was once used as the residence of the papal governors and more recently has served as a prison. The hill on which this castle stands is connected with Monte Luco by the Ponte delle Torri, with ten pointed arches, built in the seventh century.

The city experiences severe winters and has an annual precipitation averaging 44 in. Spoleto is now essentially a market and processing point for the agricultural products of the surrounding area. In the vicinity there are lignite mines. Spoleto is on the main railroad from Rome to Ancona. In 1926 a narrow-gauge electric line was opened from Spoleto to Norcia, 32 mi. east in the Apennines. Pop. 32,341 (including environs). R. G. W.

**SPONGE,** the common name for animals in the phylum *Porifera.* Sponges are characterized by their low grade of structure and their porosity. They form rounded, vaselike, or branched growths permeated with holes and permanently attached to rocks or other objects. They are unable to move, and have only slight powers of contraction, so that they seem to be more like plants, but their animal nature was established long ago. They vary in size from small crusts, or masses, to large balls or goblets that may reach a diameter of 3 ft. Sponges are usually of drab coloration, but orange, red, or yellow colors are not uncommon and blue, violet, and black sponges also occur. Although there are a few freshwater sponges, the vast majority are marine, generally inhabiting shallow waters, especially in tropical and subtropical zones. Some, however, are found in deep waters and one group, the glass sponges, typically inhabits ocean depths.

A sponge consists essentially of a mass of tissue permeated by water channels and supported by a skeleton. The tissue comprises an external flat epithelium, an interior mass of discontinuous cells of the nature of a mesenchyme or primitive connective tissue, and the channels of the water system, some parts of which consist of the chambers lined by the characteristic collar cells. The water enters by numerous small or microscopic pores strewn over the surface of the sponge, or sometimes aggregated into particular regions, and leaves by one or more large conspicuous openings termed oscula. The collar cell chambers occupy practically the entire interior of small sponges, but are reduced to clusters of small round cavities in larger types. A collar cell is a rounded cell having at its free end a transparent collar that surrounds the base of a long slender filament termed a flagellum. This flagellum keeps up an undulating movement, and the combined beating of all the flagella of the flagellated chambers causes a water current to flow through the sponge and out of the oscula. The presence of this current can be detected by adding colored particles to the water, whereupon a stream will be found flowing from the osculum with such force as to ascend considerably above the sponge. This water current is usually the only sign of life exhibited by a sponge. In a small sponge about 4 in. high, on which measurements were made, the rate of flow was found to be 3 to 4 in. per second, and it was estimated that the sponge passed about twenty-three quarts of water daily. The water current brings oxygen to the

*Sponges being sorted for market at Tarpon Springs, Florida, where warehousing and marketing are done on a co-operative basis.*

VICTOR DE PALMA FROM CUSHING

sponge, and also the minute organisms and particles on which it feeds. These food objects are caught and ingested by the collar cells, which are thus both the motor and the digestive part of the sponge.

One of the most characteristic features of sponges is the skeleton, which is imbedded in the mesenchyme and occurs in several types that furnish the basis for the division of sponges into classes. In the first class, Calcarea, or calcareous sponges, the skeleton consists of separate crystalline bodies composed of calcium carbonate. These bodies, or spicules, are either needle-shaped or three- or four-rayed. The calcareous sponges are mostly small sponges shaped like a vase and of bristly texture. They occur in shallow marine waters. The second class, Hexactinellida, or glass sponges, has a skeleton of silica consisting of six-rayed spicules, some of which are usually bound together to form a lattice. The Venus'-flower-basket is an example of a glass sponge. Glass sponges generally inhabit the ocean depths, so that they are obtained only by dredging. Little is known of their life habits. They are commonly fastened to bottom muck by a root tuft of siliceous filaments resembling glass wool. The third class of sponges, Demospongiae, includes the siliceous and horny sponges; to this group belongs the vast majority of sponges including the fresh-water forms and the bath sponges. The skeleton of this type of sponge consists of siliceous spicules of varied form (but not the six-rayed form), or of a network of horny fibers, known as sponging, or of a combination of both. The skeleton of sponges is secreted by certain cells of the mesenchyme.

Sponges have no nervous system and therefore show little response to external changes. They do, however, possess muscle cells, especially around the larger openings of the water system, and these will contract slowly on direct stimulation, or in response to unfavorable conditions.

Sponges reproduce both asexually and sexually. They have extensive powers of regeneration, and any small bit can grow in time into a complete sponge. Sponges can even be dissociated into cells, or cell masses, by pressing them through fine cloth, and these masses will come together and regenerate into a sponge. Sponges, especially the fresh-water ones, also reproduce asexually by forming round reproductive bodies termed gemmules. These bodies consist of a mass of cells enclosed in a protective surface. The gemmules are commonly formed in autumn, and tide the fresh-water sponges over winter. They hatch in spring into tiny sponges that soon grow to adult size. All sponges also reproduce sexually. Eggs and sperm are formed by certain of their cells, and resemble those of other animals. Sponges are usually hermaphroditic; that is, eggs and sperm are produced in the same animal, although not always simultaneously. The egg is fertilized while still in the sponge body, and develops there into a flagellated larva that swims about for a time, and then settles on a suitable object, where it grows.

The fresh-water sponges form a family, the Spongillidae, which belongs to the group of siliceous sponges obviously derived from marine ancestors. They occur as small growths, green or brown in color, on twigs, plant stems, boards, and other such objects found in lakes, ponds, and streams in temperate regions. They characteristically produce gemmules in the fall, after which they generally disintegrate.

The bath sponges belong to the horny sponges, which have a skeleton consisting of a network of material allied to horn. They form rounded or slightly lobulate dark-colored masses in shallow warm waters on rocky bottoms. The best localities for them are the Mediterranean, the Gulf of Mexico, and the West Indian-Caribbean region. They are taken by means of hooks on the end of long poles, or by skin or suit divers. The live part of the sponge is eliminated by various means, as treading or threshing, followed by maceration in shallow water. Finally nothing is left but the horny network, which constitutes the commercial sponge and owes its water-absorbing powers to the capillary attraction of its meshes.

L. H. Hy.

**SPONGE CRAB,** a small or medium-sized crab of the family Dromiidae which commonly fashions a closely fitting portable shelter of living sponge. The two last pairs of legs in these crabs are shorter than the others and bent upward over the back to assist in holding the sponge in place. With considerable ingenuity, the crab cuts out the sponge fragment from a living sponge and trims it to the correct shape with its pincers. As the sponge continues to grow, it forms a progressively larger shelter to conceal the growing crab.

**SPONTANEOUS COMBUSTION.** *See* Oxygen.

**SPOONBILL,** any one of several species of large, long-legged wading birds in the genera *Platalea* and *Ajaia,* closely allied to the ibises. They inhabit temperate and tropical regions throughout most of the world. They are characterized by having the long bill flattened and greatly expanded near the tip in the shape of a spoon; their plumage is mainly white, but the roseate spoonbill, *Ajaia ajaja,* a 32-in. bird of the New World, is carmine and pink. Spoonbills are found in flocks, frequenting shores both on coasts and in the interior, and nest in colonies on low trees. They feed on small aquatic animals, such as fishes, amphibians, and crustaceans, which they obtain by immersing the bill and swinging it from side to side. The American species was formerly common in the Gulf states, but is now restricted to a few localities in Florida and Texas. H. G. De.

**SPORE PLANTS,** a name applied to the three great classes of the vegetable kingdom: (1) the Thallophyta, or thallus-like plants which include the fungi and the algae; (2) the Bryophyta, or moss-like plants; and (3) the Pteridophyta, or fern-like plants. All of these are flowerless, or cryptogamous, plants in which reproduction takes place by means of spores instead of by seeds, as in the flowering plants. *See also* Bryophyta; Pteridophyta; Thallophyta. F. J. S.

**SPOROPHYTE.** *See* Bryophyta (*Alternation of Generation*); Ferns; Reproduction, Plant.

**SPOROTRICHOSIS.** *See* Mycoses.

**SPOROZOA** [spo′rozo′ə], a class of Protozoa which form spores and are parasites in animals. Organelles of locomotion are usually absent. Sporozoites, the infective stage of the parasites, are introduced into a new host either by ingestion or by bloodsucking organisms. The three subclasses are Telosporidia, Acnidosporidia, and Cnidosporidia. The Telosporidia include the Gregarinida, Coccidia, and Haemosporidia. The gregarines are parasites of the body cavity of annelids, earthworms; and arthropods, insects; and crustaceans. The coccidians invade the lining of the digestive tract causing an inflammatory disease called coccidiosis in chickens, cattle, and other animals. Besides the malarial parasites, the blood-inhabiting haemosporidians include *Babesia* the causative agent of the tick transmitting piroplasmosis of man, cattle (Texas cattle fever), sheep, pigs, horses, and dogs. *Toxoplasma* is another haemosporidian infecting mammals. It is the cause of a degenerative disease of the brain (encephal-

opathy) in rabbits and chronic toxoplasmosis in reptiles, birds, and mammals. The Acnidosporidia include the Sarcosporidia and Haplosporidia. The Sarcosporidia (*Sarcocystis*) are found in the body and heart muscles of mammals, including man. The parasites elaborate a lethal poison, sarcocystin. Recent studies indicate that this parasite may be a fungus. The haplosporidians infect invertebrates and fishes, in the latter inducing massive unsightly sores. The Cnidosporidia include the Myxosporidia, Actinomyxidia, Microsporidia, and Helicosporidia. They are parasites of invertebrates and aquatic vertebrates. Those affecting fishes are of economic significance since they are responsible for the loss of thousands of pounds of important food fishes. *Nosema bombycis* is a microsporidian that causes the silkworm disease, pébrine, first investigated by Pasteur.

R. F. N.

**SPORTING ARMS,** a term applied to firearms, including guns, rifles, shotguns, pistols, and revolvers, intended or used primarily for such sporting purposes as hunting, target shooting, competition, or recreation.

**Rifles.** The invention and use of gunpowder to propel missiles from fixed tubes, probably dates from the thirteenth century. However, the application of this principle to sports was not practicable until after the invention of an ignition system that made it possible to carry guns ready for firing at all times, without a burning fuse to frighten away game.

The first of the flint and steel locks, the wheel lock, was invented during the first quarter of the sixteenth century, and thereafter sporting weapons designed primarily for various forms of hunting began to appear. Although by the late seventeenth century a workable flintlock had been developed, this and all of the early models had the common drawback of the necessity for a pan of powder on the side of the barrel and an open hole through the barrel into the main charge, which was usually loaded down the muzzle. Runs of 18 out of 25 at skeet have shown, however, that these old guns, despite many deficiencies, were not as clumsy as popularly supposed.

Most of the guns for sporting use were loaded with a single ball. Those designed for hunting during the sixteenth and seventeenth centuries were smooth bore and were distinguished from military muskets principally by their lightness and ornamentation, as well as by the superior workmanship of their locks and metal parts.

The earliest of the true rifles also existed during this period, however, and the rifled barrel was known before the wheel-lock era, particularly in Central Europe, where the short, heavy, large-bore wheel-lock rifle, or harquebus, was a fairly common hunting weapon during the seventeenth century. However, at this time, the principal drawback of the European rifles was the common use of a bare ball the size of the bore which had to be hammered down into the barrel against the resistance of the lands of the rifling, thus making a fouled gun almost impossible to load and a clean one the work of some ten or fifteen minutes. The ball, by the time it reached the charge and was fired, was so misshapen that it was sometimes relatively little more accurate than a smooth-bore musket. However, the rifle was in fairly common use during this period, and its principles were brought to America in the early and middle eighteenth century by Central European gunsmiths.

*Kentucky Rifle.* The most typical American hunting piece, although in many cases in the eighteenth century "hunting" was classed as obtaining the necessities of life rather than as a sport, was the so-called Kentucky rifle. This was an excellent example of evolutionary principles in design, since every feature was adapted to backwoods and frontier conditions. The Kentucky rifle was, and is, a long-barreled graceful flintlock arm of relatively small bore (.40 to .50 caliber), with its sights set low on the barrel. It was designed to be used with a patched ball, which was the secret of its surprising accuracy. The ball, instead of being hammered down the bore, was wrapped in a patch of greased linen or buckskin and, being smaller than bore diameter, was rammed smoothly home with an easy stroke of a wooden ramrod.

Target accuracy comparing favorably with that of modern arms was obtained with the Kentucky rifle up to at least 100 yd., and man- or large-game-killing accuracy was possible up to two or three times that distance. Five consecutive shots touching a silver dollar at 100 yd., or striking within a six-inch circle at 250 yd. are not uncommon examples of Kentucky rifle shooting. Most of these rifles were made in Pennsylvania but were largely used by the backwoodsmen who travelled into Kentucky, hence their name of Kentucky rifles. They formed the pattern for a class of sporting rifles of a later date.

*Plains Rifle.* The "plains rifle" was typical of the early to middle nineteenth century. Linked with this was development of the percussion cap, the ancestor of the modern primer, which was the result of the application of a detonating powder (fulminate of mercury) to the discharge of firearms by Alexander Forsyth, a Scottish clergyman, in 1807. The method of filling a copper cap with a small quantity of powder and placing it on a pierced nipple at the breech of the firearm, to be struck by the hammer, was probably the invention of Joshua Shaw, of Philadelphia, in about 1816. Percussion cap sporting arms were common by 1825 but were not adopted for military purposes until the middle or late 1840's. The primer of modern cartridges is simply a percussion cap with its own anvil, contained in the head of the cartridge case. The plains rifle, for the most part, adopted the new percussion cap system of ignition soon after it came into general use. This piece had the graceful shape of the Kentucky rifle, but was shorter and heavier for use on horseback and usually of somewhat larger bore. These were the guns with which the buffalo were slain and with which the plainsmen and mountain men defended themselves from the plains Indians.

*Heavy Target Rifles.* Heavy target and sporting rifles began to appear in the 1840's and reached the height of their development shortly before the Civil War. These took advantage of the phenomenal accuracy of the conical or "sugar loaf" bullet. They were relatively short but of barrel weights from 10 to 30 lb. and were loaded by means of an elaborate false muzzle and bullet starter to seat conical bullets in muzzle-loading weapons, invented by Alvan Clark around 1840.

These were the popular target rifles of the target shoots preceding the Civil War and the weapons carried by the best of the sharpshooters during the war. Target shooting with these heavy-barreled rifles was commonly done in a manner called "rest" shooting, in which the pieces were rested on a bench or log and fired for maximum accuracy over known ranges at a mark which was primarily an aiming point. The competition was designed to produce the smallest possible group. Target matches of this sort were very popular from the 1850's through the 1870's, and bets of from $500 to $1,000 were fairly common.

*Repeating Rifle.* Inventive genius during the middle of the nineteenth century also began to produce the real boon to sportsmen, the repeating rifle. The oldest action of this type had its beginnings in the work of Hunt and Jennings in the late 1840's. Self-exploding metallic cartridges, that

is, cartridges having their own primers as well as powder and ball, were first developed during the 1850's. Those with priming in their rims, called rim-fire, were the first type, and various center-fire cartridges appeared in the 1860's. By about 1870, the general form was a brass or copper case with a pocket in its head for a separate primer, a charge of black powder filling the case completely, and a grooved and lubricated or patched lead bullet crimped into the mouth of the case to form a complete unit.

Further improvements in the Winchester design produced in 1873 a center-fire arm using the famous .44 Winchester center-fire cartridge. This was the saddle gun of the old West, and many shooters still cling to modern versions of the old lever-action design. It shared with the heavy single-shot rifle, epitomized by such extinct weapons as the Sharps, the Maynard, and others, the combined functions of hunting and Indian warfare.

This black-powder period gave rise to a series of weapons utilizing bullets which, for the most part, were from .40 to .50 caliber, had weights from 200 to 500 grains, and developed velocities from 1,100 to 1,600 ft. per second. The most powerful of these arms were accurate up to 1,000 yds.; they killed more game than probably will ever again be killed in the United States. Buffalo were commonly shot up to ranges of 400 to 500 yds.

*English Double Rifle.* European sporting rifles in the nineteenth century, and particularly English rifles, soon began to reflect the characteristics required by the increased use of sporting arms by Englishmen in India and Africa. Double-barreled sporting rifles, while not common in the United States, have been popular in England since the first encounters by Englishmen with large game in the Indian and African colonies. These rifles had the same general appearance as double-barreled shotguns, with side-by-side barrels, but were heavier than the average shotgun.

*Smokeless Powder.* A change in military arms was brought about by the development of satisfactory smokeless powder by the French engineer Paul Marie Eugéne Vieille, in 1886. This new powder, with its greatly superior power and almost complete lack of barrel fouling, made possible the small-bore, metal-jacketed-bullet, military-type cartridge with muzzle velocities between 2,000 and 2,500 ft. per second and a range two or three times that of the heavier, slower, black-powder bullet. The military rifle at that period used the turning bolt action rather than the lever or slide action to perform its repeating function. The original bolt-action, single-shot "needle" gun of Johann Nikolaus von Dreyse of the 1840's was improved by Paul von Mauser and Ferdinand Ritter von Mannlicher during the 1870's and 1880's. The modern box magazine, situated below the bolt and receiver, holding its cartridges in a single or staggered vertical column parallel to the bore rather than one behind the other in a tube below the barrel, was invented in 1879 by an American, James Paris Lee. These elements of repeating arms, appearing first in military weapons, gradually became more and more common in sporting arms of the 1890's and early 1900's although they were not popular in the United States.

*Semiautomatic Rifles.* The semiautomatic or selfloading action was adapted to sporting rifles in about 1905 by both Winchester and Remington. This principle consists of making a repeating arm by utilizing some of the gas or recoil of the explosion of the cartridge to perform the following functions: throw out the empty shell; build up pressure in a spring designed to close the breech and chamber a fresh cartridge from the magazine; and cock the piece, so that it is ready to fire again with another pull of the trigger. This has been accomplished in many types of weapons by a number of different systems, but the necessity for a separate pull of the trigger for each shot makes all of these semiautomatic weapons distinct from the full automatic arm, which continues to fire until the magazine is empty. Semiautomatic sporting rifles have never closely rivaled either the bolt- or lever-action systems in popularity.

*Modern Bolt-Action Rifles.* During World War I some four million American civilians were introduced to the uses of the bolt-action military rifle and its numerous advantages. This had the effect of changing preference in sporting rifles in the postwar period from lever-action to bolt-action types. The leading arms companies brought out bolt action repeating rifles and chambered them for newer and more powerful cartridges designed after the United States military cartridge caliber .30 Model 1906. These cartridges ranged from the standard .30'06, with its 150- to 220-grain bullet and velocities from 2,200 to 2,800 ft. per second, to the high-powered .22 center-fire cartridges, including the .220 Swift, with its 50-odd-grain bullet and velocity of 4,000 ft. per second. After further recent developments, the average modern telescope-sighted, bolt-action sporting rifle driving a killing bullet has an accurate and practical range of well over 500 yd. on reasonably well-known distances, and will shoot into a 20-in. circle at 1,000 yd. known range.

Prior to World War II, European sporting rifles built on the Mauser bolt-action were made in calibers up to .500 in standard box magazine design for heavy game hunting in Europe and Africa, and the English-type double rifles made both in England and Central Europe were still, even with modernized smokeless-powder, metal-jacketed ammunition, the standard weapons for heavy and dangerous game.

**Shotguns.** In the adaptation of firearms to hunting, it became obvious that a number of small pellets in a load, collectively called shot, was more apt to hit a bird than a single ball, so that the shotgun or "fowling" piece was developed as a distinct weapon early in the wheel-lock period, beginning the first quarter of the sixteenth century. In a reversal of modern practice, however, the wheel-lock shotgun was of smaller bore than the average rifle or military arm of the same period and also relatively lighter. Wheel-lock shotguns with a bore as small as .32 caliber in diameter are found in the larger arms collections.

*Early Gun Performance.* With the smooth-bore arm, the common weapon of the period, it was possible to use any musket or gun for shooting birds, simply by loading it with a charge of shot of appropriate size rather than a single ball. During the seventeenth and early eighteenth centuries the transition from wheel lock to the later flintlock occurred in the shotgun as well as in other types of arms, and the shotgun at this time developed into an extremely long, single-barreled weapon having a total length in many cases of over six feet, still commonly of fairly small bore. Since they were too long and ponderous for wing-type shooting, these guns were not used extensively for shooting birds in the air, but were primarily intended for shooting individual birds, either stationary or running along the ground.

*Shotgun Improvements.* At about this time, also, the trend toward the modern-type shotgun began. Better locks, placed on relatively short, double-barreled weapons, gave the shooter a chance to hit a bird in the air with fair regularity. The greatest of the English gunsmiths, and the man referred to as the father of the modern shotgun, was Joseph Manton of London (1766-1835). His influence was felt in shotgun design before 1800, and by the time he died the standard

shotgun had attained approximately its modern form of a double-barreled, half-stocked weapon of smooth lines and excellent balance. The percussion cap was applied to the shotgun and greatly speeded the action and improved the functioning of the gun. There the shotgun ceased to improve until the application of various early breech-loading systems in the 1850's and 1860's, making the arm more convenient to handle but not greatly superior in point of range or accuracy.

Finally, in about 1869, the choke bore added what was to become the greatest improvement in shotgun design. This development, giving control of patterns for close shooting, resulted more or less accidentally from experiments by Fred Kimble, a gunner in the middle western United States, who bored his gun with the hole slightly smaller at the muzzle.

The modern double-barreled shotgun, except for its superior smokeless powder load, is not greatly improved over the earlier choke bores either in range or accuracy, since no way has been found to drive the light individual shot pellets much farther than they could be driven a hundred years ago.

*Repeating Actions.* Repeating actions have been more commonly adapted to shotguns in the United States than in England or Europe. The lever action of the American Winchester was first applied in 1887; the more common slide action appeared in the 1890's and has been manufactured since. The auto-loading system, in this instance as commonly applied to shotguns, is a long-recoil action. It uses the kick of the gun to move the barrel and breechblock back about three inches and compress the springs for returning both of them to firing position. This extracts the empty shell and loads a fresh one from the magazine. It was developed by John Browning shortly after 1900, and was applied first in the United States by the Remington Co. in 1905 and later by other makers after Browning's patent expired.

**Pistols.** The earliest known pistols were heavy and relatively clumsy and, while they were used and carried extensively by "the gentry and nobility," were not commonly used for sporting weapons, except as a defense auxiliary to other arms in hunting dangerous game. The early lock improvements of the seventeenth century and early eighteenth century were passed on to the pistol, while general improvement in shape and lightness made it a practical arm for reasonably accurate shooting up to 15 or 20 yds. The eighteenth century introduced the use of the pistol for dueling.

Pistol practice for accuracy and some target shooting appeared in the late eighteenth century, but it remained for the introduction of the rifled French dueling pistol of the nineteenth century, first in the flintlock and later in the percussion cap type, to provide a weapon sufficiently accurate for serious target shooting. Particularly in Paris, shooting galleries became common and popular. Among the best known was that of Gaston Renette, which continued for many years.

*Development of Revolvers.* The application of a repeating system to the handgun was the work of Samuel Colt, who in 1836 patented a "many-chambered rotating breech pistol" and in the next fifteen years brought the design into common use.

Revolving pistols or "revolvers" in percussion cap and later cartridge designs were the common weapons of the 1850's and 1860's. In a recorded match in 1860 between Capt. John Travers, of Missouri, and another man, each contestant fired one shot at each of 15 china plates, all 9 in. in diameter and 100 ft. away. Captain Travers, breaking 11 of 15 plates, won the match. Hunting with the pistol, which had become a breech-loader using metallic ammunition, was fairly common on the Western plains, where hunters and cowboys carried revolvers in their belts and such experts as Buffalo Bill Cody and W. P. Shafe were noted for their buffalo shooting with pistols as well as rifles. While perhaps a large part of the pistol play of the old West did not come under the head of "sporting" activities, the single action Army Colt, also known as the Colt's "Frontier" or "Peacemaker," played a prominent part in the winning of the West. *See also* Explosives; Firearms; Hunting and Trapping; Target Shooting. C. T. H.

**SPORTS.** The term "sports," as used in this article, refers to "athletic sports," a term that covers a wider range of physical activities in the United States than it does in most other countries, where it is generally applicable to only track and field sports.

**Athletics in the United States.** Athletic sports in the United States include approximately one hundred sport activities in which men, women, and children participate either as individuals, as groups, or as teams. These activities include highly publicized, thoroughly organized amateur and professional sports such as baseball, football, basketball, tennis, golf, hockey, and track and field. Many of these are thought of, for the most part, as "spectator" sports, in which a comparatively small group of participants plays before large numbers of spectators. Athletic sports also include dozens of less-publicized sports, such as bowling, handball, horseshoes, shuffleboard, and softball, in which the participants engage principally for their own recreation and amusement. Baseball, football, basketball, and the other spectator sports, are also engaged in solely for the players' own enjoyment.

That spectator sports have a firm hold on the interest of sports-minded Americans was convincingly shown in the years immediately following World War II. Crowds attending sporting events in that period were of record proportions. Major league baseball attendance reached a record 20,972,601 in 1948. Horse racing was watched by record crowds everywhere, and college and professional basketball drew great numbers of people to gymnasiums and indoor arenas such as Madison Square Garden in New York and the Boston Garden. Professional golf tournaments attracted huge crowds, and important tennis matches were played before crowded grandstands. The University of Michigan football team frequently played before more than 90,000 people. Other sports that continually attract thousands of spectators include hockey, track and field, polo, and boxing. A gathering of 104,943 persons, the largest crowd ever to see a boxing match, watched the Jack Dempsey-Gene Tunney fight in Chicago in 1927. Spectators also gather in considerable numbers to see high-school football, baseball, and basketball games. The lesser-known college teams throughout the country play to sizable local audiences. Even small-town or industrial softball leagues attract sizable crowds to their games.

Telecasts of sporting events make it possible for even more American people to watch sports. Americans also follow sports events through the means of radio broadcasting and newspaper reports. The first sporting event broadcast over the radio was the Dempsey-Willard fight in 1919.

Despite this sedentary practice of watching others engage in sporting events, most Americans of all ages participate in athletic games of one sort or another. Many sports facilities

are offered and practically all of the larger communities in the United States have playgrounds. Most elementary, high, and secondary schools have gymnasiums, athletic fields, and, in many cases, swimming pools. Colleges and universities have facilities for the practice of athletic sports of every kind. Private athletic clubs in the larger cities have swimming pools, gymnasiums, handball courts, squash courts, and athletic fields. Many private clubs, devoted to one sport, provide their membership with the facilities needed for that sport. Public and private golf courses dot the country, public and private swimming clubs are available for swimming and bathing, and states and cities maintain bathing beaches and parks for residents.

According to the National Recreation Association, founded in 1906 as the Playground Association of America, the following facilities for community recreation were available in 1950 (including school facilities open to the community):

| | |
|---|---|
| Outdoor playgrounds | 14,747 |
| Recreation buildings | 2,987 |
| Indoor recreation centers | 6,633 |
| Archery ranges | 573 |
| Athletic fields | 1,933 |
| Baseball diamonds | 5,502 |
| Bathing beaches | 780 |
| Bowling greens | 220 |
| Golf courses | 454 |
| Handball courts (outdoor) | 1,953 |
| Horseshoe courts | 11,013 |
| Ice-skating areas | 3,274 |
| Shuffleboard courts (outdoor) | 4,791 |
| Ski jumps | 104 |
| Softball diamonds | 12,266 |
| Stadiums | 504 |
| Swimming pools (indoor and outdoor) | 1,616 |
| Tennis courts | 13,085 |
| Toboggan slides | 268 |

**Amateur Athletic Organizations.** In many sports, particularly football, basketball, track and field, tennis, and golf, amateur athletics retain a special dignity and prominence in the United States. The strength of amateur athletics stems from the powerful organizations that protect, guide, and rule over nonprofessional sports. The first of these organizations was the National Association of Amateur Athletes of America, which was formed in 1879 in New York City and existed for nine years. However, it was not able to control or direct the athletic sports program satisfactorily. During its existence the situation became deplorable, and the leaders in the field of athletic sports decided to form a new organization to protect and foster amateurism in American athletics. As a result, the Amateur Athletic Union (A.A.U.) of the United States was established in the New York Athletic Club on Jan. 21, 1888. The purpose of the A.A.U., as stated at the time of its organization, "shall be the improvement in, and the encouragement of, athletic sports among amateurs and the fostering and promotion of the interests of its members." It has become the most powerful organization of its kind in the world, and has played an important part in the promotion of athletic sports in the United States. It has also helped foreign amateur athletic organizations through goodwill tours, the loan of coaches, and assistance in setting up constitutions and by-laws. The A.A.U. is allied with the International Amateur Athletic Federation, and has been a decided aid to that important governing body of sports. The A.A.U. claims jurisdiction over the following sports: basketball, bobsledding, boxing, codeball, gymnastics, handball, horseshoe pitching, ice hockey, swimming, tobogganing, track and field, tug of war, volleyball, water polo, and wrestling.

The colleges of the United States have retained a separate sports identity. The Intercollegiate Association of Amateur Athletes of America was organized in 1875. Fourteen colleges were represented at the initial meeting—Amherst, Bowdoin, Brown, College of the City of New York, Columbia, Cornell, Dartmouth, Harvard, Princeton, Trinity, Union, Wesleyan, Williams, and Yale—all colleges from the eastern seaboard. Many more colleges, mostly from the east, have since joined the association. The I.C.A.A.A.A., or IC4A, has been conducting outdoor track and field meets since 1876, and since 1922 a series of indoor meets.

The National Collegiate Athletic Association was founded in December 1905 in New York City, at which time the existence of intercollegiate football was threatened because of the number of serious and even fatal injuries to players. As the result of a meeting of university presidents and college representatives, the rules of football were changed to give more protection to the players. A constitution was adopted and through it, the N.C.A.A. sought to control the rules of football, to establish better standards for the conduct of intercollegiate sports, and to serve as a clearing house for the exchange of ideas relating to student participation in athletic sports. The N.C.A.A. rules committee frames and publishes rules for football, soccer, track and field, lacrosse, swimming, wrestling, and ice hockey. It also assists the National Basketball Committee in formulating the rules for basketball. Championships are held annually in track and field, swimming, boxing, wrestling, cross country, gymnastics, basketball, golf, fencing, and tennis. The N.C.A.A. serves more than three hundred member colleges in all parts of the United States.

The National Federation of State High School Athletic Associations was founded in 1920 in Chicago, Ill. It serves as an aid to state high school associations in forty states by formulating plans and policies for improving high school athletic conditions. Over eighteen thousand schools are reported to be members of the N.F.S.H.S.A.A.

Many individual sports, such as archery, baseball, basketball, golf, softball, tennis, volleyball, and others, have separate controlling organizations which look after the interest of their members. Prominent among these are: the National Archery Association, the United States Lawn Tennis Association, the United States Golf Association, and the Amateur Softball Association. *See also individual sports.*

**SPOTSYLVANIA, BATTLE OF** [spɒ'tsɪlve'niə] (May 8-18, 1864), in the Civil War, a series of engagements below the Rapidan River in Virginia. After the Battle of the Wilderness, General Ulysses S. Grant, instead of withdrawing toward Washington, as each of his predecessors in the eastern theatre of the war had done after a losing battle, moved his army around General Robert E. Lee's right flank toward Richmond. Divining his enemy's purpose, Lee moved General James Longstreet's corps, commanded by General R. H. Anderson, to Spotsylvania Courthouse, on the road from Fredericksburg to Richmond. The fighting began May 8, when General Anderson's division attacked the advance Federal troops under General G. K. Warren. Soon both armies were engaged all along the line. Both sides entrenched, and desperate fighting at the "Bloody Angle" did not succeed in changing the tide of battle. The Federal army, awaiting reinforcements, did not avail itself of its advantages. On May 11, while both armies rested, Grant wrote his famous dispatch to General H. W. Halleck: "I propose to fight it out on this line if it takes all summer." The next day Generals W. S. Hancock and A. E. Burnside led assaults which penetrated

the Confederate line and forced Lee to take up new entrenchments. On the night of May 20 Grant moved again around Lee's right flank in the direction of the North Anna River. The Federal casualties in these engagements were about 20,000; Lee's losses were over 12,000. Lee, however, could not replace his men, while Grant had ample reinforcements. W. B. H.

**SPOTTED CAT.** *See* Ocelot.
**SPOTTED FEVER.** *See* Rickettsia.
**SPRAIN, TREATMENT OF.** *See* First Aid.

**SPRAT,** *Clupea sprattus,* a small commercially important herring, of the family Clupeidae. They are found in salt water along the north coast of Europe south to the Mediterranean. Sprats are similar to the herring, *Clupea harengus,* but with the dorsal fin inserted farther back and with strong spines edging the sharply-keeled belly. Sprat eggs are buoyant in contrast to the demersal egg of the herring. Spawning occurs in coastal waters from January until midsummer. The young, called brit, are very abundant in schools along shore and are greedily eaten by mackerel and other predacous species. Sprats may reach a length of 5 to 6 in. as adults. The young sprats mixed with those of the herring are often sold as whitebait. In Norway, many are canned as sardines. E. C. R.

**SPREADHEAD.** *See* Hog-Nosed Snake.
**SPRING.** *See* Seasons.

**SPRING,** a flow or seep of ground water escaping at the earth's surface. The term "spring" implies a flow of water, but "seeps" have the same origin and may be springs during wet seasons.

Most spring water is completely or principally atmospheric or meteoric water that has soaked into the ground from rain or melting snow. Other sources are from magmas which have crystallized to form igneous rock (juvenile water), or the water deposited with sediments (connate water). This supply of ground water is contained in the various openings, pores, and fissures in the rocks near the earth's surface. A zone of water-saturated rock occurs close to the surface in most parts of the world. The upper surface of this saturated zone is called the water table. Wherever the water table intersects the surface of the earth there will be springs or seeps. Since the depth to the water table varies from season to season and year to year depending upon rainfall, springs may change to seeps or dry up completely, or seeps may become springs. The water table intersects the earth's surface at the level of all permanent streams and lakes; seeps or springs furnish much of the supply for these bodies of water.

**Hillside Springs.** In a region of hills and valleys, some of the water which soaks in near the hilltops may reappear below as springs in the valleys above the level of the streams. This will result if there is sufficient water to keep the level of the water table above the level of the streams. In areas where some of the rocks are permeable, so that water can move through them easily, and other rocks are impervious, so that water moves through them with difficulty if at all, springs may occur where the water in its downward movement is checked by the impervious layers and is forced to move sideward and escape where the permeable layers crop out at the earth's surface. Hillside springs are usually small and of variable flow. They frequently go dry between rainy seasons.

**Artesian Springs.** A porous, permeable layer overlaid by an impervious layer may crop out at a number of places on the earth's surface. Water soaking into such a layer at the higher outcrops may reappear under pressure at the lower outcrops, thus forming an artesian spring. ("Artesian" is derived from *Artesium,* the Roman form of Artois, a region in northeastern France in which springs and wells of this type are common.) Some of these water-bearing layers (aquifers) may be of large extent, and consequently the artesian springs issuing from them may be large and of fairly uniform flow. Some famous oases in North Africa are the result of such artesian springs. In some fault springs, artesian water rises along a fault from a buried aquifer.

**Limestone Springs.** Some of the largest springs in the world occur where water issues from cavernous limestone. The carbon dioxide contained in most water that soaks in at the surface of the earth renders it capable of dissolving limestone, and consequently most limestone regions contain channels and caves formed by solution. In such regions, underground rivers are not uncommon and very large springs may occur. The Vaucluse spring in southern France, perhaps the largest in the world, has a maximum flow of about thirty thousand gallons per minute. The water issues from a limestone opening, and the spring drains a region of cavernous limestone. Silver Springs in Florida, another limestone spring, has an average flow of about five thousand gallons per minute.

**Springs from Porous Lava.** Large springs may occur where water issues from porous fractured lava beds. Along the Snake River below Shoshone Falls, Idaho, there is a series of large springs that contribute considerably to the size of the river. These springs issue from porous lavas of the Snake River lava plateau.

**Hot Springs.** Most hot springs occur in volcanic areas. The water is for the most part ordinary ground water that has been heated by the rocks which occur close to the surface near volcanoes, though a small amount may be of magmatic origin. At some hot springs the temperature of the water may be the result of the water having risen from a considerable depth, since the temperature of the rocks increases by about 1° F. for every 60 ft. of depth. Thus water that has risen from a considerable depth in artesian springs may be quite warm. Probably this explanation accounts for the warm water at Warm Springs, Va.

**Mineral Springs.** At mineral springs the water contains dissolved material in noticeable amounts. This mineral material has usually been dissolved by the water as it has passed from the surface through the rocks and back to the surface again. Warm or hot springs are the most likely to contain noticeable amounts of dissolved minerals.

**Geysers.** Geysers are erupting hot springs peculiar to volcanic areas. *See also* Geyser. J. T. W.

**SPRING,** a mechanical element of slender form that can take a large elastic deflection under load and come back to free or original form when the load is removed or relaxed. It conforms more or less exactly to Hooke's Law that deflection is proportional to load. Springs are commonly made of hardened steel with a high limit of elasticity, but in light springs other metals such as bronze and hard brass are used. The pneumatic tire acts like a spring, but is called an elastic cushion. Typical forms of spring include the plate, leaf or beam-type (wagon spring), the spiral coil (clock spring) and the helical coil. In the first two, the principal stress effect due to load is bending; in the last it is torsion.

COURTESY OF THE AMERICAN MUSEUM OF NATURAL HISTORY

*SPRINGBOK*

**Functions and Uses.** One function of the spring is to store energy. The archer's bow with instantaneous release, the oldest elastic device, is an illustration, as is the clock spring with slow and controlled release. The function of a multitude of small springs is to hold, let move, and return. Such action occurs in door locks and electric snap switches. A lock of warded-key type has a spring for its latch and one for each tumbler on the bolt. A cylinder lock has a tiny spring under each of its five little plungers. Springs are widely used on wheeled vehicles; interposed between running gear and body of vehicle, they modulate the jolts caused by irregularities of road or track. Quick movement by the wheel is first absorbed by the spring; then the unbalanced portion of the spring force imparts a slower movement to the body. The body tends to go into an oscillation, which is damped by friction (especially between the leaves of a plate spring) and in many vehicles by some form of shock absorber.

Springs are used to measure force with moderate accuracy. The spring balance, the traction dynamometer, and instruments for measuring pressure are used for this purpose. In the usual pressure gauge, a closed-end bent tube responds to variation of internal pressure, changing its curvature slightly as pressure varies. The engine indicator, with spring above small piston, measures and records rapidly varying pressures. Springs may impose determinate controlling force. This is the case in the safety valve for steam boiler and other pressure vessels. In governors for engines and turbines, spring force is balanced against centrifugal force to determine speed of running.

Some springs, such as the hairspring or balance-wheel spring of a watch or portable clock, promote continuous motion. So does the stiff helical spring that helps to actuate a valve on a combustion engine, pushing against cam action.

R. C. H. H.

**SPRING BEAUTY,** a genus, *Claytonia,* of the purslane family, having about 25 species, chiefly native to North America. They are low, spreading perennial herbs with narrow, succulent leaves and loose clusters of white or pink flowers which appear in early spring. The Virginia spring beauty, *C. virginica,* is an attractive wild flower of the eastern seaboard, and has narrower leaves than the Carolina spring beauty, *C. caroliniana,* which has the same range. The lance-leaf spring beauty, *C. lanceolata,* native from Utah west, has darker pink flowers.

J. C. Wis.

**SPRINGBOK** [sprĭ′ŋbŏk], a South African antelope *(Antidorcas marsupialis),* so called from its method of reacting to a sudden fright. Several stiff-legged bounds eight or ten feet high may so startle an enemy that the first attack fails, permitting the springbok to use its great speed and so escape. This antelope is reddish brown and has a white face and underparts. About thirty inches high at the shoulders, it weighs seventy to eighty pounds. Both sexes of the springbok have lyre-shaped horns which are fourteen to seventeen inches tall.

V. H. C.

**SPRINGER SPANIEL.** *See* Dog.

**SPRINGFIELD,** the capital city of Illinois and the county seat of Sangamon Co., situated in the central part of the state, on the Sangamon River, 165 mi. southwest of Chicago. It is historically famous as the home and the burial place of Abraham Lincoln. Springfield was settled in 1818 by a pioneer family who had moved there from South Carolina; trappers and hunters from Virginia and Kentucky drifted there during the next few years, and in 1825 the settlement became a county seat. It was incorporated as a city in 1840, having previously been chosen the capital of Illinois in 1837, primarily through the efforts of the then young lawyer of the community and member of the Illinois Legislature, Abraham Lincoln, and several of his associates. Springfield lies in a rich agricultural region yielding excellent crops of corn and other grains; livestock raising and dairying also are important. It is the center of the coal-mining industry of Sangamon Co., and has well diversified manufacturing industries, which include foundries, machine shops, and factories that produce farm implements, woolen textiles, soap, and leather. Springfield has shown a steady growth in population from the time of its inception. The city has the commission form of government.

Springfield is noted for its fine buildings and parks. The state capitol, arranged in the form of a Greek cross and surmounted by a huge dome, is one of the most impressive among the state capitols. The old State House, which dates from 1837 and has many historical associations with Lincoln's career in Illinois, is now the Sangamon County Courthouse. Among the other buildings on the capitol grounds are the Supreme Court Building; the Illinois State Armory; the State Archives Building; and the Centennial Building, which houses the State Museum, the Illinois General and Historical libraries, and various administrative departments. The outstanding tourist attraction, however, is the Lincoln Tomb and Monument, one mile north of the capitol, where the remains of the Great Emancipator, his wife, three of his sons, and a grandson rest within a crypt surmounted by a 100-ft. obelisk. The Lincoln Monument, designed by Larkin Goldsmith Mead, is situated in Oak Ridge Cemetery. The Abraham Lincoln home in Springfield, like the monument, is owned by the state and maintained as an historical shrine.

Springfield is the seat of Concordia Theological Seminary and Springfield Junior College. Transportation is provided by the Gulf, Mobile and Ohio, the Illinois Terminal, the Springfield Terminal, the Wabash, the Baltimore & Ohio, the Illinois Central, and the Chicago & Illinois Midland railroads. Pop. 1950, 81,628.

G. Q.

**SPRINGFIELD,** a city in the southwestern section of Massachusetts, the county seat of Hampden Co., situated on the Connecticut River, 92 mi. southwest of Boston and 3 mi. north of the Connecticut border. It is the third largest city

in the state and is noted as the home of the Springfield rifle and the Garand semi-automatic.

**History.** The first settlement of the community was made on the west side of the river in the spring of 1636 by a group led by William Pynchon. The fear of clashes with the neighboring Indians caused the settlers to move to the less fertile east side of the river on the present site of Springfield. In 1640 the settlement's name was changed from Agawam to Springfield, commemorating Pynchon's English birthplace. Springfield was incorporated as a town in 1641, and Pynchon was undisputed leader of the community until 1652 when he departed for England after being publicly condemned and deprived of his magistracy by the Massachusetts General Court for his heretic writings. During King Philip's War in 1675 the Agawam Indians, who had been friendly until then, destroyed much of the community in a surprise attack. At the outset of the Revolutionary War Springfield had numerous gunsmith shops, which were transformed into small factories supplying arms to Colonial forces, thus starting the industry for which Springfield is famous. In 1777 the town's small arsenal was enlarged, and Springfield became an important supply point for the Continental Army. In 1786 followers of Daniel Shays made an abortive attack on the arsenal to secure arms for Shays's "army." It was the official establishment by Congress of a Federal armory at Springfield in 1794 that determined the town's growth as an industrial community. This brought about an increasing supply of skilled workers in the town, which, in turn, attracted numerous industries because of the availability of such a labor force. Industrial development was further stimulated by the opening of a railroad between Worcester and Springfield in 1839, and in 1852 Springfield became a city. On Apr. 19, 1892, Charles E. Duryea conducted what many authorities considered the first real test of a gasoline-driven vehicle in the United States, and in September 1895 Duryea organized the first United States motor corporation, which became inactive three years later. A mayor and a board of aldermen and city council administer the local government.

**Transportation and Industry.** Air transportation is available at near-by Westfield with daily flights provided by the American, the Eastern, the Northeast, and the United air lines. The New York Central, the New York, New Haven and Hartford, and the Boston and Maine railroads furnish freight and passenger facilities. The manufacture of arms continues to be important in Springfield. The diversified factory output also includes automobile accessories, tools, electrical machinery, paper products, textiles and clothing, toys, sporting goods, castings and forgings, refrigerators, matches, air-conditioning and heating equipment, and rubber products. Publishing is also a leading industry. Pop. 1950, 162,399.

S. D. M.

**SPRINGFIELD,** a city in southwestern Missouri, the county seat of Greene Co., situated about 150 mi. southeast of Kansas City, in an agricultural area where dairying and poultry raising are important. The city is a shipping center for the products of the adjacent territory, which has large timber resources. Founded about 1830, Springfield was made the county seat in 1833, and it was incorporated as a town in 1838 and as a city in 1846. The city government is the commission type. Occupying a strategic position during the Civil War, Springfield changed hands several times before 1862 when it was seized permanently by Federal forces with which "Wild Bill" Hickok served as scout and spy. The Battle of Wilson Creek was fought near by. National and Confederate cemeteries are in the near vicinity, as is Sequiota State Park. The city is the seat of Drury College, Southwest Missouri State Teachers College, and a government hospital for the criminally insane. Transportation is afforded by the Missouri Pacific and the St. Louis-San Francisco railroads, and by the American Airlines. There are large railroad shops in the city. Local manufactures include flour, refrigerator equipment, trucks and trailers, cement, lime, stationery, clothing, and dairy products. Pop. 1950, 66,731.

**SPRINGFIELD,** an industrial city in west central Ohio, the county seat of Clark Co., situated at the confluence of Lagonda Creek and the Mad River, 23 mi. northeast of Dayton. In 1799 James Demint built a cabin overlooking Lagonda Creek on the townsite. In 1801 he planned the town. The settlement prospered despite threatened Indian trouble, which was terminated through a council in 1807 with Indian Chief Tecumseh. Springfield was incorporated as a town in 1827 and in 1850 secured a city charter. A commission and city manager administer the community. Springfield is the seat of Wittenberg College and the state homes of the Masons, the Knights of Pythias, and the Odd Fellows. Transportation is supplied by the Pennsylvania, the Erie, the New York Central, and the Detroit, Toledo and Ironton railroads. Springfield is in a fertile farming district where corn, wheat, oats, hay, and potatoes are the principal crops, and in the city there are large commercial rose nurseries. Publishing is a major industry in the city, the Crowell-Collier Publishing Company alone shipping over 200,000,000 magazines a year. The diversified industrial output includes farm implements, incubators, electric motors and equipment, trucks, automobile parts, castings, and furnace stokers. Pop. 1950, 78,508.

**SPRINGFIELD,** a town in north central Tennessee, the county seat of Robertson Co., situated 24 mi. north of Nashville, in an agricultural area where corn, wheat, and tobacco are leading crops. Hardwood timber and building stone are natural resources of the region. Springfield is the commercial center of the county, and an important shipping point for the surrounding territory. It is also a prominent loose-leaf tobacco market. Springfield has the commission type of government. Transportation is afforded by the Louisville & Nashville Railroad. The output of local industries includes tobacco products, lumber, blankets, and flour. Pop. 1950, 6,506.

**SPRINGFIELD,** a town and village in southeastern Vermont, situated in Windsor Co., on the Black River, near its confluence with the Connecticut River, about 67 mi. south of Montpelier. The surrounding large agricultural area is marked chiefly by poultry and dairy farms. Springfield was founded about 1772. The government of the town is the council-manager type. A natural feature near by is the Falls Bridge, towering high above the chasm into which the Black River avalanches. Springfield is renowned for its machine-tool manufacture. Manufactures of the town include gear-shapers, lathes, grinders, machinery, and reworked wool. Pop. 1950, 9,190.

**SPRINGFIELD COLLEGE,** an accredited, privately controlled professional school combining general education and preparation for professional leadership in youth-serving agencies. While the college is primarily for men, women are admitted to the upper level for graduate and part-time courses. The college occupies a 230-acre campus in Springfield, Mass. It was founded in 1885 as a School for Christian Workers, with a two-year professional course. The name

was changed to the International Young Men's Christian Association Training School in 1890, and to the International Young Men's Christian Association College (still its corporate name) in 1910. It is popularly known as Springfield College. The regular four-year course was established in 1916 and the graduate division leading to the masters' degrees in education and in physical education in 1926. The college is now organized with six professional majors.

Degrees offered are the B.S. and the M.Ed. in group work and community organization, guidance and personnel services, health and physical education, social science and teacher education, recreation and camping. The library contains collections of books on physical education and Y.M.C.A. history. Graduate fellowships and undergraduate scholarships are available to applicants who qualify. Foreign students are eligible for scholarship aid and they are given priority in the assignment of dormitory rooms. Residence halls are available for male students. *For statistics see* COLLEGES AND UNIVERSITIES. J. R. To.

**SPRINGHILL,** a town in Cumberland Co., Nova Scotia, Canada, 128 mi. northwest of Halifax, located on Provincial Highways 2 and 4. First settled by United Empire Loyalists, it became populous after the discovery of coal in 1834, and it was incorporated as a town in 1889. Three mines employed 1,250 men in 1947 and produced approximately 500,000 tons of coal. Pop. 1951, 7,138. D. F. P.

**SPRING HILL COLLEGE,** a college of liberal arts and sciences for men, controlled by the Jesuit Fathers of the Catholic Church. The institution is located in Spring Hill, Ala., a residential suburb of Mobile. It was founded and first instruction was given in 1830. Six years later the charter was granted by the legislature of Alabama. The A.B. and the B.S. are offered in liberal arts and the B.C.S. in business administration. Dormitories and dining halls are provided. Students from outside the city are required to live in the college residences. The national fraternities on the campus do not maintain houses for their members. Scholarship aid is limited. *For statistics see* COLLEGES AND UNIVERSITIES. J. R. To.

**SPRINGS,** a town in the Union of South Africa, 30 mi. east of Johannesburg in the southern Transvaal, and one of the oldest settlements in the Witwatersrand (Rand). It is the center of a rich gold and coal region, and its eleven gold mines produce a quarter of the total output of theWitwatersrand. Next to the mining output, the most important products are paper, pulp, brass, iron, timber, mining materials, building bricks, milled maize, plumbing supplies, and fertilizers. Agriculture in the region is well developed. The city is situated at an altitude of 5,925 ft. above sea level. Pop. 1951, 119,392. W. S. V.

**SPRINGTAIL,** the common name given to insects of the order Collembola. They are all minute (usually less than 1/10 in.) wingless insects having an incomplete metamorphosis. Most of them possess a long posterior process of the abdomen that enables them to leap into the air. Springtails often occur in enormous numbers, frequently becoming pests in moist cellars and water pipe channels. They feed chiefly on decaying matter and fungi, but the aquatic species feed on tiny animals and plants. The snow flea, *Achorutes nivicolus,* occurs on snow; the seashore springtails, *Anurida maritima,* and, *Xenylla maritima,* occur in abundance along the seashore in summer; the water springtail, *Podura aquatica,* is usually abundant along the edges of pools and ponds in summer, and many hundreds may be present on each square foot. The garden springtail feeds on plants and is often injurious. In Europe and Australia, the Lucerne flea, a bright green species, is a pest of clover. More than 1,100 kinds have been described, but little is known about their biology. C. H. Cu.

**SPRING VALLEY,** a city in northern Illinois, situated in Bureau Co., on the Illinois River, about 100 mi. southwest of Chicago. The region has extensive coal mines, sand and gravel pits, and asbestos deposits. The district's farmers grow corn, wheat, oats, and soybeans. Founded in 1876 by the Spring Valley Coal Company, the community was incorporated as a city in 1886. From December 1888 to November 1889 Spring Valley was the scene of a strike by the local coal miners. The city has the alderman form of government. John Mitchell, labor leader, made his home in Spring Valley for a number of years. Transportation is furnished by the Chicago and North Western, the Chicago, Rock Island and Pacific, and the Chicago, Burlington & Quincy railroads. Coal mining continues to be an important occupation of the city's and district's residents. The local industries produce automatic controls, iron castings, concrete blocks, neon signs, and clothing. Pop. 1950, 4,916.

**SPRINGVILLE,** a city in central Utah, situated in Utah Co., 50 mi. southeast of Salt Lake City. The city lies at the base of the Wasatch Mountains, 4 mi. east of Utah Lake. The community is the shipping center for the region's cattle, poultry, eggs, peaches, cherries, and sugar beets. Founded in 1850 by Mormon pioneers, it was incorporated as a city in 1853. Springville has the mayor-council form of government. The art collection owned by the high school and the Springville Art Gallery are local features. The gallery is the site of an annual national art exhibit. Springville was the birthplace of Cyrus E. Dallin, sculptor, and George Sutherland, Supreme Court Justice. The largest state game farm and fish hatchery in Utah as well as a Federal fish hatchery is located in Springville. Transportation is furnished by the Denver & Rio Grande Western and the Union Pacific railroads. The region's limestone is used by Springville's steel industry. The local plants include planing mills, hatcheries, a creosote factory, and a cannery. Pop. 1950 6,475.

**SPRINTING.** *See* TRACK AND FIELD SPORTS.

**SPRUANCE, RAYMOND AMES** [spru′ənz] (1886- ), American naval officer, was born in Baltimore, Md., on July 3, 1886. He was graduated from the United States Naval Academy in 1907, and was promoted through the various grades to the rank of rear admiral in December 1939. He was assistant chief of staff to the commander of the naval forces in Europe, 1924-1925, and was chief of staff and aide to the commander of a destroyer scouting force, 1933-1935. After acting as commander of the Tenth Naval District, San Juan, Puerto Rico in 1940-1941, he returned to the office of the Chief of Naval Operations at Washington and, at the outbreak of war with Japan in December 1941, he was sent to the Pacific theatre of operations. In 1942, in the Battle of Midway, Spruance administered a decisive defeat to a large Japanese naval force, and after a period as chief of staff to Admiral Chester W. Nimitz, in November 1943 he was placed in complete charge of operations during the landings of the United States Marines on the Gilbert Islands of Makin and Tarawa. He also served as

chief of the newly created Central Pacific command. He was in command of the invasion of the Marshall Islands on Jan. 30-31, 1944, and of the naval action against Truk in the Carolines on Feb. 16-17. He had tactical command of the task-force operations against the Marianas on February 22 and against Palau, Yap, Utithi, and Woleai on March 29-30. Spruance was appointed admiral in February 1944, and in April was designated commander of the United States Fifth Fleet and was placed in command of the amphibious invasion of Iwo Jima and Okinawa. On June 18-19 his Fifth Fleet won a decisive victory over a large Japanese fleet in the waters between the Marianas and the Philippines. On November 8, Admiral Spruance was named deputy commander in chief of the Pacific Fleet and, on Nov. 20, 1944, was appointed commander in chief, succeeding Fleet Admiral Chester W. Nimitz. On Dec. 28, 1945, Admiral Spruance became head of the Naval War College. He retired from the Navy on July 1, 1948, and the following January was promoted to permanent four-star rank. In January 1952 he was named United States ambassador to the Philippines.

E. B. A.

**SPRUCE,** a common name for *Picea,* a genus of evergreen trees of the pine family. The coniferous trees are of pyramidal shape and are native to the cooler parts of the Northern Hemisphere. They have whorled branches, narrow, needlelike leaves, and pendant cones found on the upper branches. The drooping cones distinguish the spruce from the firs which bear upright cones.

Seven species of spruce are native to North America, and three of these occur in the eastern United States. They are medium-sized trees, growing to a height of 100 ft. and a diameter of 3 ft. White spruce, *P. glauca,* and black spruce, *P. mariana,* are found from Labrador to the coast of Alaska and in the Great Lakes region, the former also in northern New England and the latter in New England, New York, and south, in the Appalachian Mountains, to North Carolina. Red spruce, *P. rubens,* grows from New Brunswick south through the Adirondack region and in the mountains to Georgia. In the Rocky Mountain region, there are two spruces, the Englemann spruce, *P. engelmannii,* a valuable timber tree sometimes growing 150 ft. high, and the much less plentiful Colorado or blue spruce, *P. pungens,* of similar size. The latter has a characteristic bluish-green foliage, varieties of which, including the Koster blue spruce, are popular ornamentals. The Pacific Coast spruces include the Sitka or tideland spruce, *P. sitchensis,* found along the coast from Cook Inlet, Alaska, to northern California, and also the rare Brewers, or weeping spruce, *P. breweriana,* a comparatively small tree which grows only in the coastal mountains of northern California and southern Oregon. The Sitka spruce, which often grows 200 ft. high and has a diameter measuring 8 to 10 ft. above the buttressed base, is the largest of the spruces. It yields lumber of excellent quality.

The Old World species include the Norway spruce, *P. abies,* tiger's-tail spruce, *P. polita,* and the Alcock spruce, *P. bicolor,* both native to Japan; the oriental spruce, *P. orientalis,* a native of western Asia; the Serbian spruce, *P. omorika*; and the Himalayan spruce, *P. smithiana.*

Spruce wood has a uniform texture and is moderately light in weight. It is unusually high in strength and stiffness considering its weight. Sitka spruce is obtainable in clear, straight-grained pieces of large size, and was used extensively in World Wars I and II for airplane construction. Spruce is especially suited for the manufacture of paper; the quantity of eastern spruce converted into paper pulp is equivalent to about five times that sawed into lumber. Spruce lumber is used principally for shipping boxes, light building construction, and interior finish millwork.

CHARLES PHELPS CUSHING

COLORADO SPRUCE, PICEA PUNGENS

**SPURGE,** common name for a plant belonging to the large spurge family, *Euphorbiaceae.* The name is applied particularly to *Euphorbia,* a genus of milky-juiced herbs, shrubs, and trees. Spurges also include the genus *Pachysandra,* low growing, perennial herbs or subshrubs of the box family, native to eastern Asia and eastern North America. They are used as ground covers. The American spurge or spurred gentian, *Halenia deflexa,* is a shrub of the gentian family. *See also* CROWN OF THORNS; POINSETTIA.

J. C. Wis.

**SPURGE NETTLE,** a low, shrubby perennial, *Cnidoscolus stimulosus,* of the spurge family having stinging hairs on the leaves. It grows in sandy soil in the southeastern United States. This attractive, harmless-looking plant has heart-shaped leaves and large, fragrant, white flowers. It is also aptly called the tread-softly.

J. C. Wis.

**SPURGEON, CHARLES HADDON** [spɜ′rjən] (1834-1892), English Baptist minister and one of the most distinguished preachers of the nineteenth century, was born in Kelvedon, Essex, June 19, 1834. Beginning to preach at the age of sixteen, he was soon the sensation of London, and by 1856 his success in attracting congregations was so great that his church in Southwark was enlarged and renamed Spurgeon's Church. This also proved too small, and the Metropolitan Tabernacle was opened for him in 1861; here Spurgeon ministered until his death in Menton, France, Jan. 31, 1892. He wrote fifty volumes of sermons collected as *The Tabernacle Pulpit, Treasury of David* in seven volumes, *John Ploughman's Talks* (1869), *The Gospel of the King* (1893), *The Soul Winner* (1895), and his *Autobiography* (1898-1899).

**SPURS, BATTLE OF THE.** *See* COURTRAI, BATTLE OF.

**SPY: A TALE OF THE NEUTRAL GROUND, THE,** the first successful novel by James Fenimore Cooper, based on a legend of the American Revolution told him by his neighbor John Jay, and first published in 1822. Harvey Birch, a peddler who traveled between battle lines, is suspected of being an English spy, though he is secretly in the employ of General Washington. The "neutral ground" of Westchester County, New York, houses rebel and loyalist alike, and much of the complicated plot deals with problems of the Wharton family and its divided allegiance. Young Henry Wharton is really an English spy, but his sister Frances sympathizes with the patriots. Capture and exciting escape, with Birch everywhere playing the role of deliverer, is the pattern of the book, interspersed, however, with strikingly realistic scenes of rebel marauders and camp followers, which are among the best that Cooper ever wrote. L. L.

**SPYRI, JOHANNA** [shpi'ri] (1827-1901), Swiss author of books for children, was born July 12, 1827, at Hirzel, Canton Zürich. The child of a cultured mother, who had local fame as a poetess, and of a country physician with a wide practice, she also enjoyed the stimulating variety of a large and busy household. Her many books, children's classics everywhere, thus record much of her own richly happy childhood in her native mountain environment. *Heidi,* her most renowned book, which was several years in preparation, appeared in 1880 and continues to attract children of all countries by its perennial freshness.

Johanna Spyri was one of the first Swiss women to become widely known, though her creative ability lay dormant until she was past fifty. Her unsophisticated stories depict the generalized Swiss child; they display a great love of nature, a deep understanding of the child mind, and a democratic approach. They attempt to inculcate simple piety and moral lessons. Each of her works originally carried the subtitle "Stories for children and for those who love children." She died in Zürich, July 7, 1901. L. Ba.

**SQUAB.** *See* PIGEON.
**SQUARE.** *See* GEOMETRY.
**SQUARE, MAGIC** *See* MAGIC SQUARE.

**SQUASH,** the fleshy fruit of several species of *Cucurbita* of the gourd family. The squash is believed to be native to America. The plants are tendril-bearing, often long-running annuals, closely allied to the pumpkin. The Hubbard, turban, Boston marrow, and other winter varieties are forms of *C. maxima;* the cushaw, Canada, and winter crookneck squashes, *C. moschata,* include varieties called sweet potato, Quaker pie, and Japanese pie pumpkins; summer squashes or bush pumpkins, *C. pepo melopepo,* have varieties such as pattypan, scallop, summer crookneck, and cocozelle squashes. They vary greatly in form and color. Squash, like pumpkin and cucumber, bears male and female flowers, requiring insects to bring about pollination. Weather conditions which prevent insect flight may mean a poor commercial crop.
V. A. T.

**SQUASH BUG,** the common name of *Anasa tristis* a member of the family Coreidae. Both adults and young suck the plant juices of squashes, pumpkins, gourds, and other cucurbits; often they kill the plant. The eggs are laid singly or in clusters of as many as forty on the stems or the undersides of the leaves. Adults and nymphs are usually found together, and because they spend most of their time on the underside of leaves, they may do considerable damage before their presence is detected. C. H. Cu.

**SQUASH RACQUETS,** also called squash, a game played with a 27-in. round-headed racket and a 1¾-in. black pneumatic rubber ball in an enclosed rectangular court. It probably originated at Harrow, England, before 1850 and reached the United States shortly after 1900, appearing almost simultaneously in Boston and Philadelphia. The twentieth century brought a steady expansion of the game until it became well established in schools, colleges, and clubs in England, northeastern and midwestern United States, and Canada, with club and private courts scattered over the world.

**Development.** The evolution of the game differed in England and the United States. In England, a slower ball and a higher tell-tale, or metal strip at the base of the front wall, which, when hit, put the ball out of play, made it difficult to "kill" the ball and encouraged stamina and steadiness. In America, a faster ball and a lower tell-tale offered greater opportunities for winning placements, while a narrower court aided the retriever in reaching them. English scoring makes it possible for many points to be completed with no change in the score, thus again favoring endurance, as contrasted with the American rule, which scores every point. In about 1937, considerable friendly correspondence between nations seemed to indicate that the American game was a slight favorite as to ball, scoring, and tell-tale, although many preferred the wider English court.

The popularity and rapid growth of the game can be attributed to several factors: it is inexpensive once courts are installed; it offers quick exercise to men, women, and children of all ages; it is fun for the inexperienced and a real challenge to a skilled athlete. Accomplished players customarily employ sliced and chopped strokes, using very little arm motion but considerable wrist snap. The most common shots are the drive, the volley, hard and lob services, the lob, and the corner shot, which strikes the sidewall first near the front wall, and the drop shot, a very soft shot that rebounds as little as possible from the front wall. The essentials for unusual success are a quick mind, a quick wrist, and quick feet.

Annual competitions in America and England include interclub leagues, intercity and international meets, and national, state, city, intercollegiate, and local titles of all sorts for both individuals and teams, men and women, with some doubles where courts are available.

**American Rules.** A match is begun by spinning a racket to decide who shall serve the first point. Thereafter, throughout the match, the winner of each point serves the following point. The server may always begin serving from either side, but must alternate if he serves more than one point in succession. A second service is permitted if the first is a fault. The server must place one foot within the service box, since to step on the line is a foot fault. His service must first strike the front wall, above the service line. The first bounce or contact of the ball with the floor must be within the other service court: a player stands in the box in one court and serves into the other. In traveling from the front wall to the service court, the ball may or may not strike the side walls or back wall.

The receiver may stand wherever he chooses, barring interference with his opponent's service stroke. The orthodox position is on the line separating the two service courts. He may allow the ball to bounce or take it on the fly (volley). If he plays it on the fly, the service is presumed good, provided it was good on the front wall. The receiver's shot and

all subsequent shots by both players must be played on the first bounce or on the fly, and must reach the front wall above the tell-tale, directly or via the walls, without first striking the floor or ceiling. The ceiling and tell-tale are at all times out of court. The floor is out of court until after the ball has struck the front wall. The side and back walls are out of court for a service until after the service has struck the front wall. The point continues until one player strikes the ball out of court or fails to strike it before the second bounce. Service lines, courts, and boxes have no significance after the service has put the ball in play.

**Squash Racquets Doubles.** The doubles court, standard in England and America, measures 45 by 25 ft.; it is 20 ft. high on front wall and on side walls for a distance of 31 ft. from front wall, thereafter 15 ft. high. Other dimensions are: back wall, 7 ft. high; service court, line 15 ft. from back wall; service line, 8 ft. 2 in. from floor; service box, a quarter circle 9 ft. 6 in. in radius; tell-tale, 17 in. high. The ball is regulation size but is more lively than the singles ball. The racket is the same. The rules of play and scoring duplicate those in singles, except for service. The order of service goes through the two members of each team in succession. As in singles, the service moves only when the server loses a point. Thus, in doubles, the receiving team must win two points to regain the service.

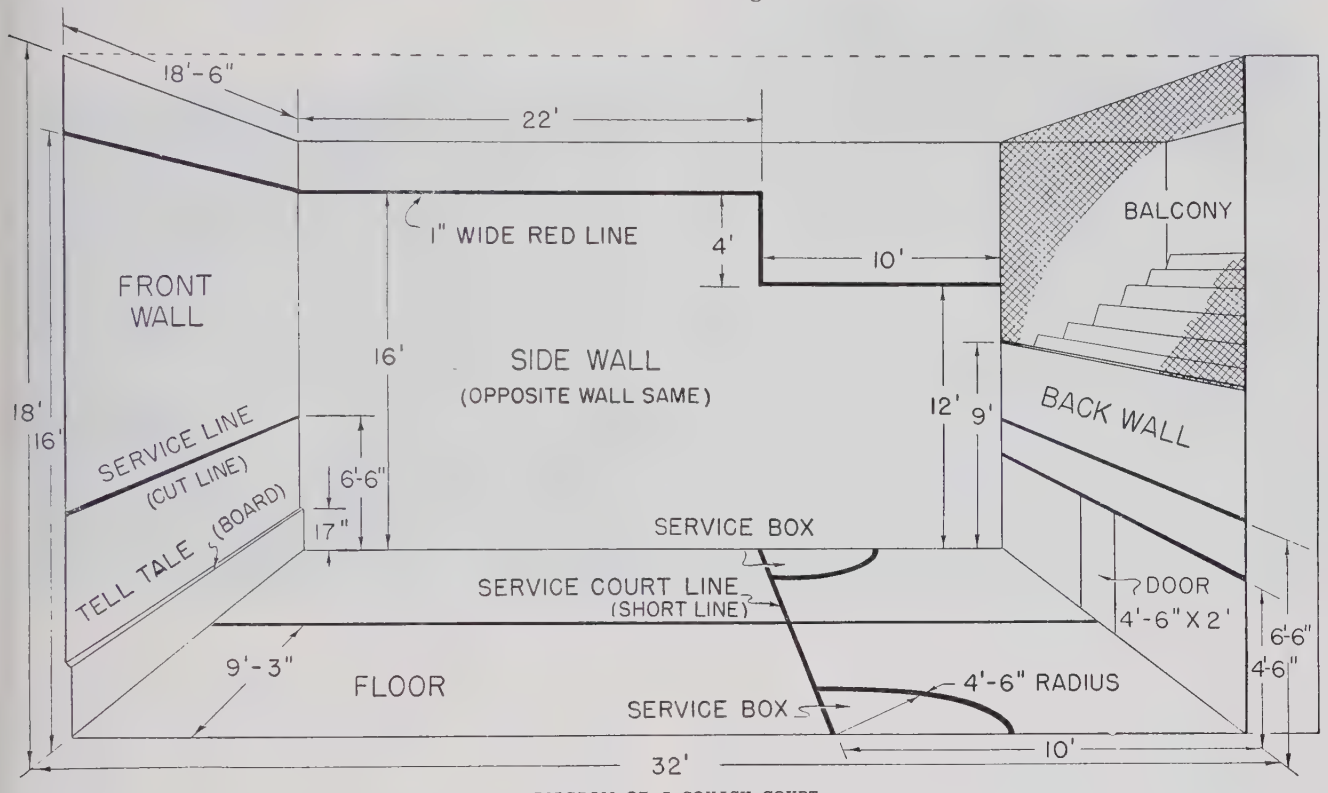

*DIAGRAM OF A SQUASH COURT*

Each player is obligated to give his opponent immediate and free access to the ball, plenty of space in which to execute his stroke, and free passage for the ball to any part of the front wall and the side walls near the front wall. He should not stand either directly in front of his opponent or very near him when he is striking the ball. Interference is subject to rules which can result, when there is a referee, in the point being awarded against the offending player. Usually, interference is only occasional and accidental; the player who has hampered requests a "let," play ceases, and the point is played again. Since rules are subject to frequent change, it is good practice for the beginner to obtain the latest regulations.

**American Scoring.** A match is the best of five games; the player who first wins three games wins the match. A game consists of 15 points, with certain exceptions. If the score reaches 13-all, the player who lost the tieing point must "set" the game at 15, 16, or 18 points; if he elects "three out of five," he is setting the game at 16, and so forth. If the score reaches 14-all without first having been 13-all, the loser of the tieing point must set the game at 15 or 17—one point, or three out of five. One minute is allowed between games; five minutes between the third and fourth games; otherwise play shall be continuous.

**Squash Tennis.** A variation of squash racquets, squash tennis was played in the early 1890's in the Middle West and the East. A racket, resembling that used in lawn tennis, but smaller, and an inflated ball, like a tennis ball with a web covering are used. The more lively ball makes squash tennis a speedier game than squash racquets, but otherwise the game is similar both as to court and method of play. Except in New York City, squash tennis has been largely superseded by the more popular squash racquets. J. M. B.

**SQUAWBERRY.** *See* PARTRIDGEBERRY.

**SQUEERS, WACKFORD,** villainous schoolmaster of Dotheboys Hall in Dickens' *Nicholas Nickleby*. His wife and daughter assist him in the outrageous mistreatment accorded to his pupils. DeL. F.

**SQUID,** the popular name for members of the ten-armed cephalopods of the suborder Decapoda. They are active, carnivorous animals found in every sea, where they prey on fishes and crustaceans. Some of them live on the surface

while others stay at great depths. They swim quickly by means of fins, but when greater speed is necessary they propel themselves backward by forcing jets of water from the mantle cavity through their "siphons." When defending themselves they can disappear behind a cloud of sepia or "ink" which they expel from special sacks within their

COURTESY OF THE U. S. FISH AND WILDLIFE SERVICE

*SQUID,* LOLIGO PEALII

bodies. The bodies of squids are usually long and conical provided with ten tentacles around the mouth. The shell is inconspicuous and located inside the body. *Architeuthis princeps,* sometimes reaching 50 ft. between the ends of the tentacles, is the largest known invertebrate. *Loligo pealii,* about 1 ft. long, is the common squid of the Atlantic coast. *L. opalescens,* the common squid of the Pacific, is the species popular in the Chinese markets. V. L. L.

**SQUILL,** *Scilla,* the common name of a genus of the lily family, with about 80 species of perennial, bulbous plants, widely found in Old World temperate regions. They bear blue, white, or rose flowers, generally in early spring. They have narrow leaves and usually low, erect flower stems. Many are cultivated as ornamentals. The bluebell of England, *S. nonscripta,* growing to 15 in. high, blooms in late spring. The Siberian scilla, *S. sibirica,* growing to 6 in. high, has vivid blue flowers, blooming in earliest spring. In medicine, the bulb of the sea onion, *Urginea maritima,* a member of the lily family native to the Mediterranean region, is used for its emetic properties; a preparation of the root is sold as "syrup of squills." J. C. Wis.

**SQUINCH.** *See* ARCHITECTURAL TERMS.

**SQUIRE, SIR JOHN COLLINGS** (1884- ), English critic, editor, and parodist, was born in Plymouth, England, Apr. 2, 1884. Educated at Blundell's School and at St. John's College, Cambridge, he began his career as a journalist, an apprenticeship that has, in many respects, influenced his subsequent work. He was associated with the *New Statesman* and founded the *London Mercury,* an influential literary publication of the 1920's and 1930's. He was knighted in 1933. Although he made his influence felt as a critic, particularly after World War I, he is especially admired as a writer of parodies, some of which were published in *Collected Parodies* (1921). Squire also wrote *Essays on Poetry* (1924), *Apes and Parrots* (1928), *Sunday Mornings* (1930), *Water Music* (1939), *Poems of Two Wars* (1940), and *Collected Poems* (1948). H. H. Wa.

**SQUIRREL,** a sciuromorphic rodent of the family Sciuridae. The word is used either to mean any member of the family, including such forms as chipmunks, ground squirrels, prairie dogs, and woodchucks, or, in the more usual sense, to refer only to the tree-dwelling forms of the genus *Sciurus.* Tree squirrels are present over most of the world, being abundant on all continents except Australia and Antarctica. Squirrels are medium-sized rodents, making nests in the branches or hollow trunks of trees, and spending most of their lives in the trees, though they descend to the ground for food or to move from tree to tree. There are two to six young in a litter, and usually a single litter per year, though in some forms there are two. Their food is largely seeds, nuts, and berries, though some forms, particularly the chickaree, will eat birds' eggs and other animal food. The gray squirrel can be very easily tamed, and is the friendly animal familiar

COURTESY OF THE U. S. FISH AND WILDLIFE SERVICE

*THE COMMON OLD WORLD SQUIRREL,* SCIURUS VULGARIS

to everyone in parks and other locations adjacent to humans. There are several fossil squirrels known, but the evolution of the group is not understood. *See also* CHICKAREE.

A. E. W.

**SQUIRREL CORN,** a smooth perennial herb, *Dicentra canadensis,* of the fumitory family, native from Nova Scotia to Virginia and westward. It grows as high as 6 in. from small yellow tubers, and has finely divided, greyish leaves. Small clusters of nodding, fragrant, greenish-white flowers, tinged with pink, appear on this herb in early spring.

J. C. Wis.

**SQUIRRELTAIL GRASS,** a common name for several grasses which bear brush-like flowering spikes resembling a squirrel's tail. Chief among these is *Hordeum jubatum,* an ornamental biennial, or perennial, growing as high as 2½ ft., of north temperate regions. It is a dangerous weed in the western United States, where its long, barbed awns are a source of injury to livestock. J. C. Wis.

**SQUIRTING CUCUMBER,** a trailing, hairy perennial, *Ecballium elaterium,* of the gourd family native to the Mediterranean region, and grown for its medicinal uses and interesting fruits. It has rough, heart-shaped leaves, yellow flowers, and small, oblong, greenish fruits, covered with soft prickles. When the fruit is ripe, internal pressure forcibly ejects the stopper-like fruitstalk, and the mucilaginous juicy pulp and brownish seeds are squirted out through the stem opening. The juice, containing the alkaloid elaterin, is dried in flakes to form the drastic cathartic drug elaterium. J. A. Bo.

**SRINAGAR** [srinʌ′gər], the capital and largest resort of Jammu and Kashmir, in the northwestern part of the Indian subcontinent. The city, about 400 mi. northwest of Delhi, India, is on the banks of the River Jhelum in the Vale of Kashmir, between the Pir Panjal Range of the Himalayas on the southwest and the main Himalayan ranges on the northeast.

Srinagar is at an elevation of 5,200 ft. above sea level. Its natural and artificial lakes, rivers, and canals, form a labyrinth of waterways in and around the city. The River Jhelum winds through the city and is crossed by seven bridges. Along the banks are moored houseboats which are the permanent homes of many of the inhabitants. The January temperature averages 35° F., but July has an average of 80° F. About 27 in. of rain falls, mostly in July and August.

Srinagar has a large silk industry, which used to make parachute silk for the British Army. Rugs, shawls, embroidery, wood carvings, art objects, and jewelry are made in small shops, and there are numerous small lumber and boat yards. Some fruit is canned and exported. The surrounding region provides mulberry leaves for silk worms; among other products are saffron, nuts, goat skins, fruits, and vegetables. Pop. 1941 (latest available), 207,787. J. E. F.

**STABLE FLY,** or biting housefly, the common names of *Stomoxys calcitrans,* a relative of the common housefly. It is also known as the dog fly. It has long shining-brown mouth parts that are swollen at the base, and it is a vicious biter of man and animals. It breeds in manure rich in straw, in decaying grass or other vegetation, and in the seaweed washed up by storms along the shores of lakes and seas. The life cycle requires only two to three weeks in warm weather. This fly has been suspected of transmitting infantile paralysis, and it is known to transmit trypanosomal infections to animals. Stable flies are a little over ¼ in. long. C. H. Cu.

*Stable fly,* Stomoxys calcitrans, *a dipterous insect resembling the common housefly, is found abundantly in stables and other farm buildings.*

**STACCATO.** *See* Musical Terms.

**STACHYOSE.** *See* Sugar Chemistry (*Oligosaccharides*).

**STADIUM,** in modern usage, a large structure containing seats for spectators, which surround a central area for competitive sports or other public exhibitions. The word "stadium" comes from the Greek *stadion,* a unit of length equal to 606 ft., 9 in. This was the distance of the original Olympian foot race, which was named for the measurement. The term was later applied to the area where the race was run, and, since the site had terraced rows of seats along the sides of the track, the name was carried over into modern usage to describe structures combining space for sports and seats for spectators.

*ROSE BOWL, PASADENA, CALIFORNIA*

SPENCE AIR PHOTOS—EWING GALLOWAY

**History.** The Greek *stadion* at Olympia and the Colosseum in Rome were the principal stadiums of early times. The Colosseum, most noted of all amphitheatres, had an extensive underground passage system and could be flooded for mock naval battles. Stadiums, however, declined in importance with the fall of Rome and were of little or no consequence during the Middle Ages. It was not until the revival of spectator sports in modern times that a new interest in such construction arose. The first modern stadium was built in Athens, Greece, in 1896 for the modern revival of the Olympic Games. It seated 66,000 and was a reconstruction of an ancient marble stadium.

**Modern Stadiums.** A few other stadiums, including bullfighting arenas in Spain and Mexico, were built before 1900, but the era of large modern structures of this type dates from the beginning of the twentieth century. Most of the large stadiums in the United States were built between 1900 and 1930. Indoor arenas were also constructed in this period, including the Chicago Stadium, seating 20,000, and New York City's Madison Square Garden, with a normal capacity of 18,000.

The United States has several of the largest stadiums in the world and has more than twenty-five with seating capacities exceeding 50,000. These capacities vary with the event,

since temporary seats are often erected on the perimeter of the exhibition area. For instance, Soldiers Field in Chicago can seat a maximum of 101,180 at football games; on other occasions, when seats can be erected on the field proper, a maximum of 200,000 people can attend events. The Los Angeles Memorial Stadium (The Coliseum) has a normal seating capacity of 101,671. The Philadelphia Municipal Stadium seats 98,993 while the Rose Bowl in Pasadena, Calif., holds 89,093. Many American universities have large stadiums primarily designed for football games. The stadium of the University of Michigan seats 98,000, and that of Stanford University, at Palo Alto, Calif., 90,000. The Memorial Stadium of the University of California and the Sugar Bowl (the stadium of Tulane University in New Orleans) seat over 80,000. The University of Pennsylvania's Franklin Field in Philadelphia has a capacity of 78,205, while the stadium of Ohio State University and the famous Yale Bowl both have seating capacities in excess of 70,000. The Harvard Stadium, one of the oldest in the country, seats 57,750 with added steel stands enclosing the open end of the stadium.

HARVARD STADIUM, BOSTON, MASSACHUSETTS

EWING GALLOWAY

Major league baseball parks generally have smaller capacities than football stadiums because of the fact that the play is concentrated in a smaller area. The largest stadium used by a major league baseball team is the Cleveland Municipal Stadium which holds 78,192. Yankee Stadium in New York has a capacity of 67,000. Other baseball parks with capacities exceeding 50,000 are Briggs Stadium, Detroit; the Polo Grounds, in New York; and Comiskey Park, in Chicago.

The Olympic Games, which in ancient Greece were responsible for the original stadium, have prompted the construction of some of the most important modern stadiums. The Athens stadium in 1896 was the first. London's White City Stadium, the first modern stadium in England, was constructed for the 4th Olympiad in 1908 and used again for the 14th Olympiad in 1948: it includes a cinder track, a swimming pool, and a bicycle path. The stadiums built in Stockholm in 1912 and in Amsterdam in 1928 were for the 5th and 9th Olympiads, respectively. The Coliseum in Los Angeles, built originally in 1923, was extensively enlarged for the 10th Olympiad in 1932. Germany constructed the huge Berlin Stadium, seating 140,000 people, for the 11th Olympiad in 1936. (Another German stadium, the Nazi Sportspalast in Nürnberg, erected in 1937, had a maximum capacity of 225,000.) One of the most modern stadiums in the world, built in Helsinki for the 1940 Olympic Games, which were cancelled because of World War II, was eventually used for the 15th Olympiad in 1952.

**Shapes and Types.** Most modern stadiums are based on Roman and Greek examples. The enclosed arena, or bowl, is similar to the Roman style, while the open end, or horseshoe type, is patterned on the Greek. Seating arrangements, exit locations, and ornamentation closely parallel the ancient models. Most stadiums are elevated; that is, the seats are constructed entirely aboveground around the playing area. Some, however, are constructed on the banks of natural or man-made depressions, with the playing field below normal ground level. Stadiums generally accommodate several sports, although they may be originally designed for only one. Baseball parks and municipal stadiums may be used for football, baseball, track and field, boxing, automobile and motorcycle racing, and other sports. However, the primary sport for which a stadium is designed governs its shape. Football stadiums are commonly single-tiered and have the greatest number of seats along the side lines, although seats usually extend all around the playing field. Baseball, on the other hand, concentrates the seats around the infield, where the principal action occurs. This leads to two- and even three-tier structures, such as Yankee Stadium and the Cleveland Municipal Stadium. Rows of seats are tiered and curved so that the playing area is easily seen from all points.

The grandstands in use at race tracks and automobile raceways, such as that at Indianapolis Speedway, are one-sided and front on only a portion of the track.

**STAËL-HOLSTEIN, BARONNE DE** [stɑ'l ɔ'lste'n] (1766-1817), French woman of letters who was usually known as Madame de Stael, was born Anne Louise Germaine Necker on Apr. 22, 1766, in Paris. She was the daughter of Jacques Necker, the Swiss banker who became Minister of Finance to Louis XVI, and of Suzanne Curchod, brilliant daughter of a Swiss clergyman, who had been the youthful love of the English historian Edward Gibbon. Germaine

MADAME DE STAËL

FROM AN ENGRAVING OF A PAINTING BY GERARD

COURTESY OF THE NEW YORK PUBLIC LIBRARY

Necker was a precocious child, and her intelligence and emotions were stimulated by the heady conversation of some of the best minds of the age in the famous salon of Mme. Necker. In 1786 she was married to the Baron de Staël-Holstein, the Swedish Ambassador at Paris, and thus acquired a position which enabled her to satisfy her ambition of establishing her own salon and playing a role in politics.

At first Mme. de Staël welcomed the French Revolution with enthusiasm, and her salon became the center of the constitutional party. However, she was forced into exile numerous times, especially under Napoleon, with whom she seems at one time to have had the vague dream of associating herself in power. Her *De la littérature* (1800), animated by a love of republican ideas of freedom and expounding the doctrine of perfectibility, made her suspect to Napoleon, who ordered her to withdraw forty leagues from Paris. *De l'Allemagne* (1810, 1813) was an even greater challenge to the Emperor. Its development of a theory already adumbrated in *De la littérature,* namely, the superiority of northern European Romantic literature over southern European, Classical literature, made it an important early manifesto of Romanticism. The book idealized Germany, which Mme. de Staël had learned to know well during her exile. Napoleon had the plates destroyed, and it was only in 1813 in England that the book finally saw the light.

Not being able to engage in politics during her exile from Paris, Mme. de Staël had turned to fiction and composed *Delphine* (1802) and *Corinne* (1807), both thinly veiled autobiographical novels that plainly show the influence of Rousseau. The latter, a far superior work, besides constituting an excellent guidebook to Italy, presents an idealized portrait of the author, giving her the physical beauty which she lacked and craved and portraying the difficult existence of the intellectually and artistically superior woman. After a long and stormy liaison with Benjamin Constant, Mme. de Staël secretly married (1812) a young officer, Albert de Rocca, who was half her age. After the fall of Napoleon she returned to Paris, where she died, July 12, 1817. R. A. P.

**STAFFORD,** county town and municipal borough in Staffordshire, England, situated about 120 mi. northwest of London, on the Sow River. It is a manufacturing center. It was formerly named Betheney and as such is mentioned in the Anglo-Saxon Chronicle. About 1050 it had a royal mint. William the Conqueror built a castle in Stafford, which was dismantled by Oliver Cromwell. The first charter was granted by King John in 1206. In 1918 Stafford was included in the parliamentary division of the county. The area of the town was extended in 1934. Izaak Walton was born and died in Stafford and was baptized in St. Mary's, the parish church which was built during the Anglo-Saxon period. The manufacture of boots and shoes is the principal industry. With Stone, Stafford returns one member to Parliament. Pop. 1954, 40,750. A. W.

**STAFFORDSHIRE,** a central Midland county of England, with an area of 1,158 sq. mi. It is bounded by Cheshire and Derbyshire on the north, Derbyshire and Leicestershire on the east, Warwickshire and Worcestershire on the south, and Shropshire on the west. The Trent River Valley intersects the county in a northwest-southeast direction. The northern part of the county is mostly wild moorland; the rest is level or gently undulating. Staffordshire is the third most important industrial county of England, but much of it is still rural. The Potteries, the earthenware manufacturing district, is celebrated as the Five Towns of Arnold Bennett's novels. The area really has six large towns: Hanley, Burslem, Stoke-on-Trent, Longton, Tunstall, and Fenton. The pottery industry is an old one. Josiah Wedgwood started his factory at Etruria, the Spodes theirs at Stoke, in the eighteenth century. The Black Country, famous for its iron manufacturing, is in southern Staffordshire. Wolverhampton, the capital of the Black Country, has been known since Elizabethan times for its locks and keys. It now has ironworks and hardware manufactures of all kinds. There are valuable coal fields in the county, and gypsum and zinc ore are mined. Salt is made from brine here, and there are breweries at Burton-upon-Trent, and silk spinning and dyeing establishments at Leek. Stafford, the county town, birthplace of the angler Izaak Walton, manufactures boots. Dr. Samuel Johnson was born at Lichfield. The county returns six members to Parliament. Pop. 1952, 1,620,000. S. Van V.

*Memorial to Dr. Samuel Johnson in the Market Place at Lichfield, Staffordshire*

**STAG BEETLE,** the name given to a family of large beetles, the Lucanidae, which usually have greatly developed mandibles in the males, suggesting the antlers of male deer. Although the beetles are able to pinch quite strongly, they are entirely harmless. The mandibles, which are chiefly ornamental, may be used for grasping the female during mating. The male is known to use them in fighting. This group includes the largest beetles, which may be over 4 in. long. Stag beetles are often called pinch bugs. C. H. Cu.

**STAGE,** the separate place in the theatre where plays are enacted.

Development of the stage is connected with the appearance of the actor in the antique theatre who used the supporting steps (*bema*) of the altar (*thymele*) during his presentation. He moved later to the open section of the auditorium (*theatron*), outside of the orchestra circle, in order to find himself in a more frontal position to his audience. A wall, later a wooden hut (*skene*), acted as a background, and the projecting wings (*paraskenia*) served to enclose the actor in a courtyardlike space, while framing his movements against the open landscape.

The actor soon achieved a desired dominating height by occupying the roof of the skene building (*logeion*), thus originating the first "stage." The higher level (*theologeion*), required for the appearance of the deities in the Classic tragedies, brought about the construction of an additional level resulting in an architectural repetition. With these innovations the antique theatre developed the basic form of the stage as an elevated, distinct place reserved for the actor. The use of different doors, such as the center door (*porta regia*) for royalty, and side doors (*hospitalia*)for slaves, gave the first symbolic significance to the place of the action.

During the fourth century B.C., the Greek theatre, which was originally a religious-ceremonial assembly place, witnessed a gradual transformation into a more theatrical auditorium. First came an attempt toward straightening out of the seats (Dionysos theatre). Later, the elimination of the overhanging wings resulted in a reduction of the size of the theatron, this being the first attempt to decrease the distance between actor and audience. The art of portrayal was still restricted to the person of the actor, yet sporadic scenic effects appeared. The abnormal height of the logeion gradually decreased. With emphasis on the theatrical element, the Roman stage grew to enormous proportions, finally occupying half of the orchestra circle and stretching over the whole diameter (180-300 ft.). The façade of the building itself, the richly decorated *scaenae frons,* represented a further advance toward scenic ideals, remaining, however, only an architectural ornament. Therefore, the stages of the antique theatre were classified as an architectural stage of permanent nature (*scaena stabilis*).

There were no permanent theatre buildings in the Middle Ages, and the stages for their occasional performances therefore consisted mostly of various types of simple platform construction erected on public squares (Lucerne, Valenciennes) or they were placed on wheels and drawn through the streets of the village (English pageant wagons). The illustration of Biblical themes was the motivation of these performances as arranged by the Church. This resulted in the employment of scenic representations, e.g., The Manger, Heaven, Prison, and Hell Mouth. These Mystery plays demonstrate how the art of portrayal of the actor spread to his environment. The "little mansions" (*domus*) were placed at the back of the platform in a row, creating the so-called *décor simultané.*

With the discoveries of the laws of perspective, the Renaissance architects Bramante (1444-1514) and Sebastiano Serlio (1475-1554) developed the "angle wing" type of setting, which enabled them to present the illusion of larger space conceptions, such as a public square or the vista of a whole city or garden. These settings were far more effective than the "little mansions" of medieval practice. Placed on a sloping stage, the vistas served for background, behind the actual platform used by the performers. Simultaneously, the interest of the humanists in antique culture resulted in the revival of ancient tragedies and with them the corresponding performance practice. The Teatro Olympico in Vicenza (1584), based on plans of Vitruvius Pollio, the Roman architect, was a replica of Roman architectural stages complete with the traditional five doors. The Serlian type of perspective vistas was placed behind the openings of the *scaenae frons.* In his book on architecture Serlio left a description of this stage upon which, in accordance with ancient tradition, three types of settings could be exhibited, i.e., the tragic, comic, and satyric scenes. Serlio used perspective scenery, painted on angle wings and mounted, three on each side, on a sloping rear stage which was terminated by a back shutter. His stage had unwieldy stability, though it was not as rigid as Palladio's Teatro Olympico stage built during 1580-1584. The increasing importance of the ever-changing colorful settings of the *scaena mobile* was soon recognized by Giovanni Battista Aleotti, who in the Teatro Farnese (1618) enlarged the opening of the *porta regia* to such an extent that the full width of the stage floor was filled with a single vista. This first modern setting, by eliminating the permanent architectural stage, placed the actor on the same stage with the scenery. The *porta regia,* transformed into a proscenium arch, created a sharp dividing line between stage and auditorium, making two separate architectural units. While the architectural type of stage was carried on by the Elizabethan theatre in the use of the apron stage without scenery, in the proscenium type of theatre the actor and his environment became framed, and the "peep show" stage made every effort from this time on to convert itself into a "world of illusions."

Demand for quick scenery changes for the "intermezzi" or interludes between the acts of the legitimate plays overtaxed Serlio's efforts. An inspiration from Vitruvius' treatise on architecture solved the problem. Architects found that the Greeks used the *periaktoi* to indicate scene changes. The Renaissance architects reviewed these triangular revolving prisms and proceeded to use the idea. The designer Bernardo Buontalenti became famous (1585-1589) for his *a vista* shifts of scenes painted in perspective.

The stage designer Sabbatini invented (1637) a number of mechanical devices modeled on the triangular prisms, e.g., *scaena versatilis,* in order to surprise the audience with quick-changing settings. Shortly after this invention, the angle-wing system was replaced by free-standing wings sliding in grooves on the stage floor (*scaena ductilis*). This improved method gave even more opportunities for variation in shape and subject. While the number of different settings employed within one presentation continuously increased, more and more machines were employed to satisfy the ever-growing desire for spectacle. During the seventeenth century complete triumphal processions were transferred to the theatre, which demanded extraordinary depth of the stage (Salle de Machines, Paris, width 33 ft., depth 130). Flying angels and goddesses descending from the clouds required the development of extensive flying space above the stage. The counterweight system operated by drums and pulleys was in common use for lifting the drops and borders of the fantastic settings of the Bibienas (eighteenth century). The fly galleries received further importance in operating the enlarged drops and arches of the nineteenth-century Classic and Romantic eras. Although surpassed by present-day technique, they still can be found in many contemporary modern theatres. The rigid separation of stage and auditorium culminated in the satirically called "mystical abyss," under the demand of Richard Wagner in the construction of the Festspielhaus in Bayreuth, where the unusually deep orchestra pit represented an insurmountable barrier between stage and auditorium.

The decline of the theatre of illusion toward the end of the

nineteenth century resulted in the change from the merely painted scenery to the three-dimensional, plastically built, naturalistic settings. This innovation presented a new demand in scene change devices. Thereafter, revolving panels, elevators, and rolling wagons were installed in the stage floor for handling the massive set pieces. With the replacing of illusion-creating settings by the physical realities of built-up scenery, the framing function of the proscenium arch became obsolete and gave new opportunities to the pioneers of the modern experimental theatre (Max Reinhardt, Walter Gropius, Usevolod E. Meyerhold). These modern experimenters, in order to balance the close-up technique of the cinema, and perhaps to exploit new beauties of three-dimensional space, are seeking to establish a closer relationship between actor and audience. Modern designers, by introducing various types of apron, relief, and space stage construction are trying to break into the domain of the auditorium. This trend has resulted in the appearance during the 1940's of the arena type of theatre plan, as well as actual performances with completely circular auditoriums (Pent House Theatre, Seattle, Wash.; "170 Productions" of Ralph Freud at the University of California at Los Angeles).

**STAGE PRODUCTION IN THE UNITED STATES.** With the possible exception of the motion picture, there is no other art that depends for its completion on so many elements, so many people, and such diverse talents as the art of stage production. After an author has written a play, it is not fulfilled until it is brought to life. Its words must be spoken by living actors, who move before the eyes of an audience, make their entrances and exits, and enact the story.

When a theatrical producer buys a play, he is concerned with this very task of bringing the written word to life. He must find the financing and engage the director, and then, with the approval and help of the director and author, he engages the cast and the scenic and costume designers. When a star is engaged for the play, he or she will have a voice in some of the decisions, especially in those regarding the supporting cast, the designers, and the general character of the production. Often the producer is his own director, and sometimes an author will direct his own play. In any case, director and producer must work closely together, and, when a modern play is presented, the author also has considerable authority. Over-all responsibility for the production lies with the producer, but the director is the guiding hand.

A. F. B.

**Direction.** Stage direction is the art of bringing to life on the stage the characters and incidents that have been imagined in a dramatist's manuscript. The manuscript may be likened to blueprint designs of a machine. It is the director's function to assemble the parts, put the machine together, and make it run. His work begins with the dramatist, to whom he may point out parts that, to him, seem defective, overstressed, or understressed. The director's next function is to work out with the scene designer the mood and treatment of the settings, costumes, furnishings, and lighting.

From the beginning, the director has been surveying casting problems, and if these are found seriously insoluble actual production is delayed. Casting completed, the director starts rehearsals, and here begins the welding of all elements into one all-inclusive pattern, as originally envisioned. To the extent that he succeeds, he will reveal a smooth-running machine, with all parts so functioning that no part falters, clatters, or shakes loose.

Until comparatively recent times, the stage director, as the co-ordinator of all departments of presentation, was little known. The physical production was largely left to the scene painter, the property master, and the manipulator of lighting. The direction of the actors was largely in the hands of the leading actor or, occasionally, the author. There was no planned over-all pattern. Augustin Daly (1838-1899) was perhaps the first American stage director as direction is now understood. Following him, and further pursuing the method of full authority over all expressions, from the virgin manuscript to final birth, was David Belasco (1854-1931).

Relations between director and cast vary. There is the director who wants to act all of the parts, who sees actors not as creators but as imitators. Far removed from the thespian director is the director who tries to stimulate the actor's own creative potential. To the extent that the projection is imitative, the director is to be given full credit or blame. To the extent that the interpretation is creative, both actor and director are involved. In the final analysis, the director must assume full responsibility for all that has been permitted, encouraged, or discouraged, for the whole effect is the director's —the essence, the flavor, the illumination.

When direction is perfect, it will be unnoticed. The director's methods, like the magician's, should not be evident; he is clumsy if the rabbit is seen getting into the hat. The stage at its best is legerdemain and hypnotism, and these are the arts of the stage director.

A. Ho.

**Design.** Usually a stage designer has an opportunity to read the play that is to be given before he is engaged for the production. Then he and the producer agree on dates for the delivery of designs, scenery, props (properties), and costumes, as well as the dates for rehearsals and for the opening performance. After further study of the play to determine the type of design best suited to the script and to the budget, the designer makes a sketch, or more frequently several sketches, of his settings. These he submits to the producer along with floor plans of the settings, showing plainly the location of entrances and exits, windows, fireplaces, the masking pieces, the cyclorama, and the outside dressing; he will also indicate the placing of the principal pieces of furniture. The floor plans are most important, for the action of the play is contained in them, and from the floor plans grow the elevations, or the walls of the room, or, in an exterior scene, the trees, shrubs, walls, or masking pieces. With all of these drawings, the designer gives color samples of walls, woodwork, furniture covering, drapes, and so forth. There are many ways to design a play and each person concerned with the production has ideas of his own, but the director knows what he wants and the final decision rests with him.

*Scenery.* Stage scenery is built of wood, covered with canvas, and the canvas is painted to simulate whatever is indicated in the design. Certain parts of the scenery, such as doors, window frames, mantelpieces, and columns, are built separately and are stained or painted as required. When the designs are approved, the designer makes his measured drawings for the builders. These are carefully dimensioned, half-inch-scale mechanical drawings; from them blueprints are made, and enlarged details are drawn up wherever necessary, usually for fireplaces, moldings, or ornamental details. A one-act play usually requires two or three sheets of drawings; an elaborately designed musical or a play of many sets requires as many as ten or twenty sheets. Sometimes a scale model is made; but most directors and producers are content with scale drawings.

Scenery paint is a mixture of powdered pigment, glue,

size, and water. Color samples are usually made in water color or tempera, for oil color has a different quality and samples in oil could not be exactly reproduced. Where a room is to be done in wallpaper, the design must be furnished to the painter, since no real wallpaper is ever used on a set of scenery; such paper is not fireproof, it is seldom correct in scale, and it is flat and uninteresting. Wallpaper designs are reproduced on scenery with a series of stencils. A half-inch-scale painting of every backdrop is made, as well as paintings of borders, side pieces, and masking pieces.

When the contracts for building and painting are assigned, it is the duty of the designer to supervise the work in progress. No matter how precise the drawings, there can always be differences of interpretation, and the designer may be obliged to pay almost daily visits to the builder. Stock moldings and trim are often used, and if so the designer selects them and their numbers are marked on the blue print. On completion, the scenery is shipped to the painter's studio, where the painter makes samples of color on a piece of canvas or an old piece of scenery before starting work on the sets. Scene painting is not just flat laying on of color, like house painting; it is a process of vibrant painting, one tone applied over another in order to create the illusion of atmosphere. Under the changing light of the stage, surprising variations in color may develop, and in order that the designer may have his finished scene exactly to his taste, he must supervise the painting job during the entire time that it is in progress.

*Props.* Theatrical properties are everything that is seen on the stage except scenery and costumes. The draperies, carpets, furniture, pictures, ornaments, trays, knives and forks, plates, cups and saucers, cigarette boxes and ash trays, artificial flowers, books, lamps and lighting fixtures, trees and shrubs—the countless things that give reality to the set—are all procured by the designer. All are under the care of the property man except the lighting equipment, for which the head electrician is responsible. The property man will sometimes furnish things that do not come within the sphere of design, such as false money, foreign or outdated newspapers, or old letters, but even these are usually submitted to the designer before being used. Stage telephones are the responsibility of the electrician.

The assembling of props is a long and tedious business. Before going into rehearsal, the director decides how many pieces of furniture he wants and where they are to be placed on the stage, but this decision is subject to change as work on the play progresses. The director's needs must always be satisfied, by purchase or otherwise, even though such specifications as the height or depth of a sofa are not easily met. The renting of props, whenever it is possible, is a common practice, for it results in a great saving in the initial cost of a production. Props that cannot be found must be made, and remarkable representations of real objects are turned out in studios that specialize in such work. For example, pot-bellied iron stoves, marble statutes, foods of all sorts, Welsh harps, and street organs can be reproduced in papier-mâché at a fraction of their true weight.

The property man is also responsible for off-stage noises such as galloping horses, shattered glass, pistol shots, sustained gunfire, thunderstorms, and banging doors. He has noise machines, a drum for thunder, a coconut shell manipulated on a board by hand for the horses' hoofs, and phonograph records for bands and crowds, but he uses a real door in a frame to produce the sound of a banging door and real glass for shattering. Off-stage noises often raise perplexing problems. In Chekhov's *The Cherry Orchard,* for example, the author's direction is: "At this point a sound is heard like the breaking of a harp string." In one production of the play, the sound thus indicated was found to have no resonance, and, after many experiments, the desired effect was obtained from the twang of a musical saw.

*Costume.* The moment an actor comes on the stage to play his part, he is in costume. He wears the particular kind of dress that the man he represents would wear, just as he speaks the words the author has written for the character and not his own words. The costume of the actor is the heightening, the translation into terms of character, of everyday clothing; when this is successfully done, the designer is not merely a copyist, but a creator.

As he reads the play, an experienced designer forms a mental picture of the costumes, just as he does with the scenery. He makes sketches and then confers with the director, sometimes also consulting the principal actresses and actors before completing his drawings or ordering his costumes. A costume must be correct in line, period, and character; it must suit the actor or actress; and it must be in harmony with the rest of the production. Costumes for the entire cast must be designed as a whole, in relation to each other and to the scenery and movement of the play. In color they must harmonize with the draperies and the furniture covering.

The execution of costumes is difficult, for most costume drawings are not clear statements of design and they are interpreted with great latitude. Costumes can be made from numberless kinds of material, and since the quality, weight, and pattern of a fabric are of primary importance to the success of a design, the task of selection requires talent of a high order. Costumes for plays in a modern setting, if they are not specially designed, are usually bought or made to order; those for period plays are usually rented. In any case, they must be fitted to the wearer in the short time (normally three or four weeks) allowed for rehearsals. The designer is obliged to supervise the fittings, and it is a measure of his responsibility that much of the success of a costume depends on whether or not it is worn by the actor or actress with confidence. The effect of lighting requires careful consideration, and many directors call for a dress parade on the lighted stage after the costumes are completed.

*Lighting.* Lighting the stage is an important part of the designer's work. With his blueprints he gives the manager a light plot, indicating how much equipment he will need and where it will be hung. The head electrician is engaged for at least a week before production opens and is often present when the equipment is ordered. Lighting units are rented for nearly all productions, for there are no permanent lights on any stage of a commercial theatre, except possibly a border light, which is a long strip of ordinary lamps that cannot be focused or changed. It is unfortunate that all productions have to carry their own electrical equipment, for the cost of hanging and dismantling is very high; but this cost varies greatly, of course, with the type of play that is being produced.

Lighting is, in a sense, the final touch of any production. It permits an entire audience to see the movements and expressions of the actors; it enhances the beauty of the scenery and costumes; it establishes the time of day; and it creates atmosphere and mood. In general, it has the effect of fusing all the elements of a production in one harmonious whole.

Lighting equipment for the stage consists of electric lamps of different power, shining through lenses and modified by gelatin mediums of different colors. The lamps, or spotlights, have flexible frames so that they may be turned and

focused on the object to be lighted. They are hung on pipes overhead behind the proscenium arch, or at the sides of the proscenium, and some are placed on the balcony rail so that their rays can be directed across the auditorium to the stage. There is usually a strip of light known as an X ray, which is hung overhead among the spotlights and consists of four, six, or eight rigid lamps; there are also strips of lights that are used to illuminate the top and bottom of the cyclorama, and flood lights to give added brilliance. All of the lights are controlled from a switch board, with dimmers. Properly used, they will give exceedingly subtle and dramatic effects. New and better equipment is constantly being made by the lighting laboratories, and the advance in stage lighting has been one of the most notable technical achievements of the modern theatre.

**Final Preparations.** About three weeks and a half after rehearsal starts, the scenery, props, costumes, and lighting equipment are picked up by a theatrical trucking company and delivered to the theatre where the play is to open. Formerly, when costs were lower, it was the custom to hold a scenery and dress rehearsal in a theatre in New York, before shipping the material out of town; in fact, some plays opened in New York without benefit of tryout away from the city. Now, however, the material usually goes directly by train to wherever it is needed. Two or three days are allowed, in an ordinary production, for setting up scenery and lighting and for dress rehearsal. Many more are needed for elaborate productions with a number of scenes and for musicals and reviews.

The stage manager and the designer are in the theatre while the scenery is set up and the lights are hung. Every play that goes on the road has its own crew, including a head carpenter, a head electrician, and a head property man. These have as many assistants as the show requires, and there is, besides, a resident crew in every theatre. When the show comes to New York, the road crew remains with it, working with the crew that is assigned to the New York theatre. Since the cost of crews during rehearsal is high, all possible steps to facilitate the setting up of scenery are taken in advance. The head carpenter is largely responsible for this and, of course, for the proper designing and supervision of the scenery. No matter how carefully scenery is built, there are irregularities in the fitting of joints, doors, and window frames when it is set up in a theatre, owing to imperfections of pitch in the stage floors. In some of the old theatres on the road, floors sometimes slant upward as much as a foot toward the back wall, but stage carpenters have become accustomed to dealing with this inconvenience. While the scenes are being set, the electrician hangs the lights and makes his equipment ready for the work of focusing the spot and of covering the lenses with colored mediums.

As soon as the scenes are set, the property man lays the rugs, hangs the pictures, distributes the furniture and small stuff, and checks his off-stage props. The stage manager shares these responsibilities with the property man, for he knows what is needed for the action of the play. In fact, he is the representative of the director at this time. He knows what the positions of the cast are to be and at what point in the action the lights will dim or brighten, and he is responsible for giving the cues to the head electrician. The lights are now adjusted, the actors take their places, and the dress rehearsal begins. Thereafter, in the few days that may remain before the opening performance, changes in cast, in lines, and in scenes or costumes may be required. After the opening night, the production stands or falls largely on the merits of all the labor that has gone before.

### PRODUCTION OUTSIDE OF NEW YORK CITY

Play production in the United States is at present localized in New York, where most of the country's best builders, painters, property makers, and costumers are found. It is the central point for actors and actresses, except for those in the film industry on the West Coast. A great deal of the capital for production comes from New York; and the film companies that supply some of the capital place a higher value on a play that has won the stamp of approval of New York critics and audiences. A few plays are produced in Los Angeles, San Francisco, or Chicago, but they are negligible. Some plays enjoy a long run on the road before appearing in New York, opening in other cities, and touring extensively if business warrants; but the productions are made and rehearsed in New York. After the New York run, they may go on tour again. In the case of enormously successful plays, one or more additional companies may be formed, the scenery and costumes being duplicates of those in the original production.

Road travel is popular with the touring companies, for they are rewarded by the enthusiasm of the audiences and refreshed by new contacts with places and people. In the big cities, the run may be from one to four weeks or more; elsewhere, split weeks and one-night stands often require night travel, but the physical discomforts of the schedule are balanced by the excitement of the road. In spite of travel costs, a road company with a successful play may make a substantial net profit.

A few cities maintain their own stock companies. The plays that they present are usually Broadway successes, but occasionally there are revivals of the classics and, very rarely, a new play. The companies normally have a resident designer and scene painter and build and paint their scenery in the theatre. Costumes for period pieces are hired, and, unless something out of the ordinary is required, modern clothes are supplied by the actors and actresses. The plays run a week, as a rule, with the result that there is neither time nor money for creative designing. The designs of the original production are followed as closely as possible, the scenery is usually rebuilt and repainted from old materials, and the properties are gathered where and how they can be had. Although the productions may be shabby and uninteresting, these stock companies often develop an excellent quality in acting, a certain harmony that comes from association in work.

Summer theatres are a comparatively new operation in America. Like the stock companies, they also produce plays that have had the stamp of Broadway approval, but they produce new plays as well, some of them try-outs of later successes. As a rule, the summer theatres have a semipermanent company, fill out the cast with visiting stars or well-known character actors, and employ a resident designer and painter, supplemented by amateur help. Many young men and women learn their trades in a summer theatre. It is an excellent school, for the stage is usually small and the materials are limited, and designing under these conditions is a challenge to the imagination of the young designer or craftsman.

A. F. B.

**STAGG, AMOS ALONZO** (1862- ), American football coach, was born Aug. 16, 1862, in West Orange, N. J. He was educated at Phillips Exeter Academy and Yale University, where he played end on the varsity football team, being chosen on Walter Camp's first all-America team in 1889. Stagg studied for the ministry after graduating, but decided he lacked the necessary eloquence for the pulpit,

and in 1890 began coaching the football team of Springfield (Mass.) College, also playing as its captain. Stagg went to the University of Chicago in 1892 to head the physical education department, a position in which he remained for forty-one years, developing many of the greatest American football teams and players. He coached five undefeated elevens, won the Western Conference championship seven times, and tied once for the national championship, and his over-all record was 268 games won and 141 lost. During most of his stay at Chicago eastern teams dominated football, but Stagg made effective use of his material and in time became generally recognized as the country's leading originator of football plays. Among these were the principle of the hidden ball, the "ends back" play, the "turtle back," the end-around play, the fake kickoff, and the double delayed pass. Stagg also invented the tackling dummy.

An age-limitation rule forced Stagg's retirement from the University of Chicago in 1933, but although past his seventieth year "the Grand Old Man of Football" refused to end his coaching career, and the next year found him drilling a new team at the College of the Pacific in Stockton, Calif. The school was relatively small, but Stagg gradually built teams of major caliber, and his success was so outstanding in 1943 that the nation's coaches voted him "Coach of the Year." He left in 1946 to become advisory coach under his son, Amos Alonzo Stagg, Jr., at Susquehanna College. Stagg's high ideals and his devotion to football as a molder of character have been recognized in many awards and honors. He is the only life member of the Football Rules Committee. He was the only man chosen as both player and coach among the first members of the College Football Hall of Fame established at Rutgers University in 1951. He has co-authored *Treatise on American Football* (1893) and an autobiography, *Touchdown!* (1927). G. Q.

**STAGGERBUSH,** a member, *Lyonia mariana,* of the heath family, native from Rhode Island to Florida and westward. It is a slender shrub growing as high as 6 ft., having oblong leaves, and bearing numerous, handsome, nodding clusters of pinkish or white flowers, in late spring, on leafless branches. It is poisonous to livestock, especially sheep.
J. C. Wis.

**STAGHORN FERN,** an epiphytic, perching fern of Australia and the tropics of Asia and Africa. The fertile fronds, erect or drooping, branch in a way that gives the appearance of a pair of antlers. The sterile fronds are flat and rounded, and remain close to the support on which the plant grows. The common staghorn fern, *Platycerium bifurcatum,* and several other species are grown in conservatories. The spread of the fronds sometimes reaches 6 to 8 ft.
G. M. Sm.

**STAINED GLASS,** a term specifically used to refer to the translucent colored glass of the great pictorial church windows of northern Europe. The earliest of these windows date from the tenth century of the Christian Era, though colored glass itself had been known for many centuries previously. The Egyptians made glass imitations of precious stones. The Romans had opaque glass mosaic plaques and rosette ornaments of twisted varicolored strands. Later, in the Near East, a jewellike wall decoration was achieved by colored chips of glass set kaleidoscopically in the masonry or plaster. But none of these early applications can be considered fine art. Only when in the North stained glass became an adjunct of Christian architecture did it attain high artistic status.

**Origins.** Many characteristics of northern windows originated in southern and eastern countries. The use of glass to cover openings in buildings was introduced about A.D. 300 in the basilicas of southern Europe. It was the Arabs of the Near East who used translucent pieces of colored glass in walls of mosques and palaces and later devised geometric and floral designs resembling wall mosaics. It was the Arabs, too, who developed pointed window frames with delicate stonework. The marked influence of East-European Byzantine illuminated manuscripts and of cloisonné enamels, made also of colored glass and lead, is also apparent in the early Gothic windows.

It was in France, England, Germany, and the Netherlands, however, that the art of stained glass reached its fullest realization, and here it became one of the great achievements of European culture. Many factors influenced this development. A transcendent religious impulse was evidently necessary before the miraculous vibrant aspects of colored glass could be put to appropriate use. Light architectural forms were also needed, and Southern Romanesque architecture was too heavy to encourage display of elaborate glass; furthermore, the glare of harsh southern sunlight weakened the effect of translucent colors. But the most important factor was that it was in the North that the great religious revival furthered by Charlemagne reached its greatest intensity. A wave of church and cathedral building was started in the tenth century and was well underway in the eleventh and twelfth centuries.

To create picture windows, the knowledge of how to make glass in many colors was necessary. The color range of the ancient craftsmen had been too limited for pictorial compositions, but a general interchange and increase in knowledge took place when scholars and craftsmen fled westward to escape the Arab conquest, later, when the Crusaders traveled East. Thus around the ninth and tenth centuries the Medieval glass-makers learned how to produce many additional colors in "pot-metal," i.e., glass colored by various oxides or by gold or silver particles while molten and still in the crucible. They also developed the technique of "flashing," a process whereby a colored glass and a white glass are blown together and the resulting glass, in two layers, alters the intensity of the color.

**Techniques.** It is well to remember that lead as well as glass played an important role in stained glass windows, and lead strips as well as iron bars were an integral part of both construction and design. To construct the windows, the Medieval craftsmen used a whitewashed top of a trestle table which was at least twice the size of the proposed window panel. On one side was drawn the cartoon, or heavily outlined pattern; on the other side the glass was assembled. The process of construction, which remained basically the same for centuries, was something like the making of a jig-saw puzzle. The pot-metal was blown into a cylinder, cut, and flattened. A wetted fragment was placed over an outlined section, and cut to conform to the cartoon lines by the pressure of a red-hot pointed iron. Rough edges were smoothed and filed by a hooked "grozing iron" (diamond cutting was adopted about 1500). Then the pieces were placed in the proper position at the other end of the table.

After the pieces of glass were assembled, grooved strips of lead joined in the shape of an irregular "H" were inserted and soldered at the joints. These held the pieces of glass and lent both physical and aesthetic strength to the design. Finally, the finished glass panel was weather-proofed and elevated and attached by copper wires to iron saddle bars in the masonry of the window opening. It was in effect a great

mosaic of contrasting colors and dark lead lines. Some lines were painted in a brownish-gray pigment on the surface of the glass to define the facial expressions and the draperies. The pigment was made of powdered oxide, a powered glass, and putty and became known as "grisaille." Each fragment of glass on which lines were applied was painted separately and fired in a kiln at high temperature to fuse the pigment permanently to the surface. Another means of surface decoration was discovered early in the fourteenth century when silver oxide applied to the surface was found to color the glass a pleasant yellow tint of varying depth. This yellow tint extended the subtlety and variety of coloring.

The plan of the windows was from the outset carefully supervised by religious authorities, for the strong dramatic quality and emotional appeal were self-evident. The central workshops at Chartres, Bruges, and elsewhere, from which workmen, materials, and designs were probably often dispatched abroad, were under the direct charge of the clergy.

**History.** The earliest mention of pictorial church windows occurs in two tenth-century manuscripts that refer to the windows at Reims and to the leading of valuable windows at Fleury-sur-Loire. The earliest glass now in existence is at Augsburg, where five fairly small eleventh-century panels, each depicting a prophet, have a dignity and solemn majesty that is more Romanesque than Gothic. This is also true of the slightly later window, with exceptionally effective leading, at Canterbury showing the Patriarch Jared. There is a Byzantine quality apparent in these windows. Another variation of Byzantine influence is apparent in the only other existing eleventh-century glass window: the Ascension panel at Le Mans.

Typically, these early windows show prominent, often single, figures and use large pieces of glass, heavy leading, and often pastel colors. In the borders, when they occur, designs are formal, stiff, and stylized, and the motives often Classical in form. A conventionalized treatment of acanthus leaves is frequent.

The spirit of the windows changed in the mid-twelfth century when this comparatively stiff style was replaced by the introduction of medallion windows. The Gothic Cathedrals were described as textbooks in stone, and it is not surprising that the didactic possibilities of stained glass windows would soon be put to use by the Church. Instead of single figures as subjects, whole stories were presented chapter by chapter in medallions. The medallions, circular or, later, quatrefoil, were outlined by iron armature. The emphasis on storytelling caused window openings to become larger and higher, and the pieces of glass smaller and more detailed. The arresting features of the brilliant windows set in the dark interiors was exploited to the fullest by the increasing use of jewel tones and dazzling detailed backgrounds. The play of light was carefully studied. The use of blue and red which merged into purple was characteristic of the thirteenth century, especially in France, where these colors, in trellis-work background, are exemplified at their most dazzling in Sainte Chapelle, the curved walls being almost entirely of high glass panels. In England, scroll work filled in the intervals between medallions. After about 1250 the windows as a whole achieved a great liveliness and vitality. Border motives were rhythmic, more natural, and no longer strictly schematic. Franciscan gentleness and love of warmth and nature characterized many late thirteenth-century windows. Within the medallion framework, composition achieved compact force, and the color was of great brilliance. This is generally considered the greatest period of stained glass.

Probably the earliest medallion windows are those at Canterbury, Sens, and Chartres. The Cathedral of Chartres is the great treasure-house of twelfth- and thirteenth-century glass. It contains the blue Tree of Jesse window, the famous Belle Verriere window showing the Virgin and Child enthroned, and a great window depicting the Passion. There are three rose windows at Chartres. Circular rose windows are set high in a façade, and, because details of stories would not be visible at that height, they are not narrative but have instead radiating, isolated motives of design. The sections, frequently consisting of formal rosettes set in arches, point toward the circumference. The effect is kaleidoscopic and purely decorative. When, in 1926, the rose window at Reims, destroyed during the First World War, was restored, this form of design engaged the attention of many people previously unfamiliar with Gothic windows.

Eventually the splendor and color of the twelfth- and thirteenth-century glass gave rise to a counteraction. The Cistercian and later the Franciscan monastic orders issued edicts protesting the overly rich and worldly effects. These mendicant orders were the spiritual heirs of the Byzantine monks whose illuminations had inspired the use of jewel colors as a means of direct appeal and expression and who had also understood the religious needs of the individual communicants. The Franciscan and Cistercians also understood these needs and preached directly and comprehensibly to the people, extolling love of the small and humble and the virtues of the poverty and austerity present in daily life. In the thirteenth century the monastic orders acquired enormous power. Between 1221 and 1264, 8,000 Franciscan monasteries were established. When, at first in the mid-twelfth century and intermittently thereafter, their orders promulgated puritanical edicts prohibiting lavish windows, they effected the introduction of a monotone "grisaille" type of decoration, consisting mostly of leading on white glass (as at Angers, Chalons, and Salisbury) or of painted grisaille line ornament on white (as at Reims, Sens, St. Jean aux Bois). With increased use of line, the canopy and architectural details received more attention. The austerity of grisaille windows was sometimes relieved by a small colored medallion or, later in the early fifteenth century, by prominent use of colored glass on grisaille background, as at Exeter and York Minster in the famous "Five Sisters." The silver oxide tinting for yellowed effects lessened the severity of grisaille windows; and later, for example, when not only pattern work but figures were depicted on grisaille, golden aureoles and haloes appeared.

The Black Death of 1350 further modified window designs. This plague was of such dire proportions that it altered philosophic and religious attitudes of northern Europe and lessened the influence of the Church. No longer was the Church central and universal in its authority, and no longer were forms of art centrally dictated. Geographically interchangeable types, symbolic figures, ornaments, and signs were replaced gradually by actual landscapes, specific figures, contemporary costumes, and local plant forms. The Black Death had the effect of weakening faith in the hereafter and of strengthening interest in the immediate world and ordinary living. It also awakened a desire for isolation, regionalism, and security from intrusion. Although the subject matter remained predominantly religious, some secular windows were made featuring coats of arms and heraldic devices. The earliest heraldic shield devices are of the thirteenth century at Westminster Abbey and are forerunners of the later heraldic windows. For these, "flashing" is particularly important, for the details were too small to allow

contrasting solid glass with each change of color. The necessary minute coloring was accomplished by scratching away lines in the upper layer of flashed glass, revealing the different color beneath without recourse to leaded sections.

After the fourteenth century, sweeping generalizations about chronological design developments are made more by way of arbitrary convenience than strict analysis. With isolated regional activity and national schools, the rate of change was not uniform. There are, however, broad period ascriptions used by most art historians, and they are convenient for a cursory survey to indicate the general history.

The stained glass periods are usually defined as follows: of the earliest period, the eleventh- and twelfth-century windows at Augsburg and Le Mans have been mentioned, as has the early Gothic period at its height in the thirteenth century with notable examples at Chartres; the following Middle Gothic of the fourteenth century, in Germany called the "Geometric" period, in England the "Decorated," is marked by the increase in national differences and by line drawing; the later Gothic of the fourteenth century, in England called the "Perpendicular," in France the "Flamboyant," in Germany the "Interpenetrated," was decidedly regionalized and foreshadowed the Renaissance delight and pride in technical achievement.

After the mid-fifteenth century, rising humanism and individualism gradually affected the northern countries and culminated in the Renaissance. The spirit of anonymous dedication almost disappeared from glass making. Designers of windows were often known by name, signatures appeared, and patrons and donors were identified. Problems of perspective and "photographic" realism challenged the skill of the artists more than immaterial ideology.

Enamel painting came into use at this time. Sometimes this involved the scratching away of paint from a covered surface in an etching technique. The sixteenth-century windows were made with far greater pictorial freedom than before. Small domestic windows with genre scenes and landscapes became not uncommon. Until the middle of the seventeenth century these small windows were made in a combination of pot-metal, grisaille, and enamel, "as solid and permanent," according to Mr. Joep Nicholas, "as the all pot-metal medieval windows." St. Gudule in Brussels and Gouda in Holland have splendid windows from this period. Some seventeenth-century secular grisaille windows in England show imagination and humor and depict strolling players and comic figures as well as a feeling for the problems of domestic architecture.

After the middle of the seventeenth century, windows degenerated to mere paintings on glass, and the enamelled surfaces eventually cracked and peeled from weathering since the paint did not expand and contract with the glass. The small secular windows made by the Swiss are an exception, for on them the enamel did last admirably.

The eighteenth and early nineteenth centuries paid little attention to stained glass. During the second half of the nineteenth century, however, interest in imitating the earlier windows and designing modern ones in a romantic spirit revived in England with the pre-Raphaelites, with William Morris and most especially Burne-Jones, and in France with the ardent, antiquarian interest of Viollet-le-Duc. In the United States increasing wealth prompted the construction of many pseudo-Gothic churches with windows of varying quality. As communities expanded in America, churches were often erected in Gothic style with imitative glass work. In the more elaborate buildings, care was taken to have the inevitable stained glass windows designed to reproduce as closely as possible the fervor and jewellike effect of the great twelfth- and thirteenth-century masterpieces. John La Farge designed domestic windows executed by Tiffany, but these were not at all in the Gothic style, being more in the spirit of contemporary book illustrations. Connick, Saint, Heaton, and Joep Nicholas are notable among the great twentieth-century window designers; the last-named has designed several windows in modern form as well as great reproductions of the Gothic spirit. Since World War II the resurgence of religious feeling has stimulated an interest in church windows, some of which have been planned by modern painters and tapestry designers. In a new church at Assy, in the French Alps, stained glass windows are again an important architectural feature and have been designed by fifteen prominent French artists including Rouault, Lurçat, Leger, Arp, and Braque.

**STALACTITE WORK.** *See* ARCHITECTURAL TERMS.

**STALIN, JOSEPH VISSARIONOVICH** [sta'lın] (1879-1953), leader of the Union of Soviet Socialist Republics and of the Communist Party from the death of Lenin in 1924 until his death in 1953, was born in the Caucasian village of Gori, Georgia, on Dec. 21, 1879. His mother was Ekaterina Georgievna and his father was Vissarion Ivanovich Dzhugashvili, a worker in a shoe factory in Tiflis. Stalin received his preliminary education in the Gori parochial school and in 1893 entered the seminary at Tiflis, an institution which had considerable influence upon him during his formative years. Clerical restrictions caused him to rebel, and by 1897 he was the leader of a Marxist group within the seminary. Communist-inspired literature says that Stalin was expelled from the seminary because of these activities, although this has been denied by his mother who insisted that she removed her son because of his poor health.

*JOSEPH STALIN*

SOVFOTO

After leaving the seminary, Stalin worked as a clerk in the Tiflis observatory, although his main interest in life was the Russian Social-Democratic Workers' Party, the Tiflis branch of which he joined in 1898. In this association he became a professional agitator, fostered mass strikes and demonstrations in Tiflis and Batum, and finally ran afoul of the police in 1902. He was arrested in Batum, where he spent a year in jail before being transferred to Kutaisi. In 1903 he was exiled to Siberia but later escaped and returned to Tiflis to resume his revolutionary activities.

While in Siberia, Stalin learned of the famed party split between the Mensheviks and the Bolsheviks and cast his lot with the latter. Stalin concerned himself almost entirely with the publication of underground revolutionary literature. His paper, *The Struggle for the Proletariat,* was, next to Lenin's, the most important Bolshevik periodical. In December 1905 Stalin attended the party conference at Tampere, Finland, where he met Lenin for the first time, thus beginning an association which eventually resulted in Stalin's inheritance of the leadership of the party after the death of Lenin. On June 26, 1907, Stalin organized and directed a robbery of the State Bank truck which was transporting funds from the railway station at Tiflis. This feat, which swelled the party funds by 340,000 rubles, brought about his arrest in Baku, where he served eight months in prison before being exiled to Solvychegodsk in the province of Vologda. While there, his wife, Katherine Svanidze, whom he had married in 1904, died of tuberculosis. Stalin subsequently, in 1919, married Nadezhda Alliluyeva (died 1932).

The period 1902-1917 was a tumultuous one for Stalin, consisting of a series of arrests (six), imprisonments, exiles, and escapes. Between times he was engaged in writing and publishing revolutionary literature. Following the March 1917 revolution he arrived in Petrograd, and with Leo Kamenev took charge of *Pravda,* the party's journalistic vehicle and still the official voice of the party. By this time he had completely dropped his real name of Dzhugashvili in favor of Stalin, which means "man of steel." In May 1917 Stalin was elected a member of the Politburo, the all-important governing body of the Soviet, and in 1922 was appointed by Lenin to the post of Secretary General of the Communist Party. During the civil war (1918-1920) he played an active role in gathering food and supplies for the Red army. He was particularly active in the Stalingrad area (then Tsaritsyn), and when that city was under fire of the White army he participated in its defense. It was during the civil war years that the breach between him and Trotsky, then Commissar of War, grew to serious proportions. He frequently disregarded and often countermanded Trotsky's directives. When Lenin died in 1924, Stalin formed a triumvirate with Zinoviev and Kamenev which successfully opposed Trotsky and his followers. Some mystery surrounds the finale of the relations between Lenin and Stalin, for the former is alleged to have left a last testament with his wife which said, among other things, "Stalin must be removed. He is too rude and this fault, supportable in relations among us Communists, becomes insufferable in the office of the Secretary General." Stalin, with the co-operation of Lenin's widow, is supposed to have suppressed this statement, although he did make reference to it some years later when his position had become secure. The last chapter in the contest between Stalin and Trotsky was written in 1927 when the latter attempted to convert the celebration of the anniversary of the revolution into a mass demonstration against Stalin. The attempt failed, and in December Trotsky and seventy-odd members of the opposition were expelled from the Communist Party. In January 1928 they were exiled. That same year Stalin inaugurated the first of the Five-Year Plans, a vast program of industrialization and collectivization which had as its purpose the placing of the Soviet on a firm economic basis. The Five-Year Plan was carried on despite the many hardships it wrought on the population and opposition from the rightist side of the Communist Party.

During the mid-1930's Stalin began to meet with serious resistance within the party. Then occurred the famous Moscow trials and equally famous purges. Such old comrades as Alexis Ryckov, Nicholas Bukharin, Gregory Zinoviev, and Leo Kamenev were placed on trial and eventually sentenced to death. The methods used to obtain confessions of betrayal, and the general air of inexorability which characterized the conduct of the trials, revealed to the outside world the nature of the Soviet dictatorship.

In August of 1939 Stalin surprised the world by engineering with Hitler the famous nonaggression pact between Germany and Russia. For the moment, the agreement was hailed as an instrument for peace and one that would contribute much to calming the troubled waters of Europe. But its true significance was revealed a month later when Stalin's Red army marched in and occupied one-half of Poland after that country's defeat by Germany. Further indications of Stalin's imperialism were brought to light by the Soviet attack on little Finland in November 1939 after that nation had refused certain territorial demands. On May 6, 1941, Stalin became the official head of the Soviet when he assumed chairmanship of the Council of People's Commissars (later named Council of Ministers). This event preceded by but a few weeks the break with Hitler and the Soviet Union's about face, which resulted in the invasion of the U.S.S.R. by the German army.

During World War II Stalin's leadership and iron will were credited with aiding in the defense of Moscow against the advancing Nazi armies and in their final defeat. He gained the title of Field Marshal on Mar. 7, 1943, and of Generalissimo on June 28, 1945. With President Roosevelt and Prime Minister Churchill he attended the Teheran Conference in 1943 and the Yalta meeting in 1945 and with President Truman and Churchill, the Potsdam meeting in 1945. After the war Stalin's attitude toward his former allies became inconsistent and unpredictable. He vacillated between protestations of friendship for the democracies and charges of imperialism. His policies seemed to be reflected in the Soviet conduct in Berlin and in its support of Communist China and North Korea.

Stalin's 29-year rule came to an end on Mar. 5, 1953, when it was officially announced in Moscow that he had died in the Kremlin at the age of 73 after being stricken with a brain hemorrhage four days earlier. F. W. P.

**STALIN.** *See* VARNA.

**STALINABAD** [stɑ'lɪnɑbɑ'd], the name of a region in the Tadzhik Soviet Socialist Republic of the Union of Soviet Socialist Republics, and of the capital of both the region and the Tadzhik S.S.R.

**The City.** Stalinabad, a manufacturing town and capital, is in the southernmost Soviet Union, about 130 mi. southeast of Samarkand and 92 mi. north of the Afghanistan frontier. It is located on a tributary of the Kafirnigan River, in an irrigated basin, at the southern foot of the Hissar Mountains. The modern city was built during the Soviet Five-Year Plans on the site of the old mud-hut village of Dyushambe. Its phenomenal growth brought a population increase of over 1,000 per cent from 1926 to 1939. Institutions include an institute of medicine and schools of agriculture and veterinary science. It lies on a branch of the Trans-Caspian Railway from Bukhara. Trade is in raw cotton, silk, fruit, lead, and arsenic. The principal manufacture is silk fabric. Pop. (est. 1950), 130,000. C. C. H.

**The Region.** The region of Stalinabad is bounded on the north by the Ura-Tyube Region, on the east by the Garm and Kulyab regions, on the south by the Kurgan-Tyube Region, and on the west by the Surkhan-Darya Region. Three

economic zones exist: the mountainous zone, the arid zone, and the irrigated valleys. Dominated by the Hissar Range, the western extension of the Alai Mountains which rise to elevations of more than 18,000 ft. above sea level, the first zone is a region of mountain pastures. The arid zone is a semidesert plateau, thinly populated by farmers who maintain limited herds. Economically the most important, and the most densely populated, the third zone comprises the valleys of the Vakhsh and of the Zeravshan rivers. Both are protected by the barrier of the Hissar Range from the cold winter winds that blow in from the Siberian lowlands. The Vakhsh Valley is outstanding for its production of long-staple Egyptian cotton. In the Zeravshan Valley the same crops that are to be found in the Samarkand section of the oasis appear: alfalfa, cotton, rice, sugar beets, vegetables, melons, mulberries, pistachio nuts, grapes, figs, barley, and a variety of temperate-zone fruits. Inhabiting the region are Tadzhiks, constituting 75 per cent of the total population, and Uzbeks. A network of new roads has been built leading to Tashkent, Leninabad, and Khorog. A railroad also connects Stalinabad with the Uzbek Soviet Socialist Republic.

W. S. V.

**STALINGRAD** [stʌlɪngra′t; stɑ′lɪngrad], the name of both a governmental region and the city that is the administrative seat of that region, located in the Russian Soviet Socialist Republic, in the southwestern Soviet Union.

### THE CITY

Stalingrad, formerly Tsaritsyn, is an industrial center on both banks of the small Tsaritsa River, about 380 mi. southeast of Kharkov. It is situated on a flat terrace on a high bank of the lower Volga River near its "elbow" at its closest approach to the Don River.

**History.** Although its actual date of origin is unknown, the city was first mentioned as a frontier fortress in 1589. A small town frequently attacked by marauding tribes during the sixteenth and seventeenth centuries, it was taken by the Cossack robber Stenka Razin in 1670 and was the scene of hostilities in the Pugachev Rebellion between 1773 and 1775. During the nineteenth century its importance increased as a transshipment point for goods shifted between the Don and the Volga, while railways further accelerated its growth. In the civil war from 1917 to 1920 the city was a key defense point against Krassnov's White Army attacks when Joseph Stalin personally directed the Red army's liberation of the city. In honor of Stalin's strategic leadership during the liberation, Tsaritsyn was renamed Stalingrad in 1925. During the First and Second Five-Year Plans, industries developed rapidly, and the population increased nearly 300 per cent by 1939.

**Battle of Stalingrad.** The city's fame became universal after the Soviet army's heroic defense against the Nazis in World War II. The German plan was to cut the vital supply artery of the Volga at its westernmost point; success in such an operation would have been a crucial blow to Russian defenses, whether at Stalingrad or elsewhere along the Volga. Fully realizing the strategic necessity of retaining the city, Russian commanders met the first attack in August 1942 with unprecedented stubborn defense. Nazi bombs and artillery leveled the town, and German troops finally reached the center of the city; but Soviet troops held Mamai Kurgan Hill, overlooking the city, and no German troops crossed the Volga. In January 1943 the Red army turned the tide, repulsed the Germans, and by February 2 had freed the city, capturing 330,000 Nazi troops. The Battle of Stalingrad, one of the fiercest in history, marked the beginning of the decline of German military power in the war and is one of the great turning points in military history. The intense house-to-house fighting left virtually nothing intact in the city; all buildings were destroyed and factories wrecked.

**Streets and Buildings.** Reconstruction began in 1943 and had made considerable progress by 1950. Twenty thousand carloads of debris were moved out of Stalingrad in a five-year period. Of interest is the Square of the Fallen Heroes, in the center of the city, dedicated to the defenders of 1919 and 1920. Institutes of agriculture, medicine, mechanics, and pedagogy are also located in Stalingrad.

**Commerce and Industry.** As the economic and industrial center of the lower Volga, Stalingrad contains many large industrial establishments, especially the Red October Steel Plant and a huge tractor factory, both destroyed in the war but restored afterward. There are also oil refineries, sawmills, wood-working plants, shipbuilding yards, grain mills and elevators, and chemical, clothing, canning, and leather factories. There is a large port on the Volga, and goods are transshipped either on the Don River or by long-distance rail lines which focus on Stalingrad. Pop. (est. 1954), 450,000.

C. C. H.

### THE REGION

The Stalingrad Oblast (Region) is contiguous to the Voronezh and Saratov oblasts on the north, the West Kazakhstan Oblast on the east, the Astrakhan Oblast on the south, and the Rostov Oblast on the south and west. With an area of 52,264 sq. mi., it slopes from the pre-Volga Heights in the northwest to the low Ergeni Hills in the south. Deflection, caused by rotation of the earth, has caused the Volga River to cut into the heights, already a strongly dissected plateau, thus creating an extremely steep western bank. Along the eastern side of the river stretches fairly flat terrain. Between the heights and the Ergeni Hills is a low depression, undoubtedly at some time in the past the former channel of the Volga River. At this point the Volga and the Don rivers are separated by only 60 mi. The Volga-Don Canal, completed in 1952, bridges the gap and provides the city of Stalingrad, located at the depression, with a water-route to the Black Sea in addition to its connection with the Caspian Sea.

Steppe conditions prevail throughout the Stalingrad Region as a result of precipitation which averages 14 in. annually, but often falls far below that amount. The region suffered a great drought and famine in 1921. However, more moisture occurs on the pre-Volga Plateau than on the plains to the east of the river, since the high western bank acts as a barrier to the moisture-bringing westerly winds. For this reason, and because of the fertility of the chestnut-brown plateau soils, the inhabitants engage in agriculture and cattle raising on the plateau and sheep grazing on the eastern plains, where the camel is the principal beast of burden. Spring wheat, sunflower seed, mustard seed, grapes, winter rye, oats, and spring barley are the chief crops. A strip of rich, alluvial land on either side of the river is tilled also, producing cotton and vegetables. Fishing, tanning, and textile making are other occupations of the peasants. In the eastern section are lakes which produce salt. In spite of the small number of industrial centers, the region is relatively thickly populated. Pop. (est. 1954), 1,500,000.

W. S. V.

**STALINO** [sta′lɪnə], the name of both a governmental region and the city which is the administrative center of that region, located in the southeastern Ukrainian Soviet Socialist Republic, in the southwestern Soviet Union.

**The City.** The city is an industrial community about 105 mi. northwest of Rostov. Stalino was founded in 1872 as Hughesovka or Yuzovka by a Welshman named Hughes, who had been granted a concession by the Russian government to manufacture iron rails. Its population increased 250 per cent under Soviet Five-Year Plans. Captured by the Nazis on Oct. 21, 1941, it was retaken by Soviet troops on Sept. 8, 1943; the city was almost destroyed in the fighting. Points of interest, many of which were destroyed or damaged in World War II, included the industrial institute of the Donets, the House of the Soviets, an opera house, three colleges, several theatres, and a large municipal park. As the oldest steel-manufacturing town and the main metallurgical center of the region, it is considered the "capital" of the Donets Basin ("Donbas"). One of the most rapidly developing Soviet industrial cities, it has many coke ovens, blast furnaces, and steel works. It uses Donets Basin coal, iron from Krivoi Rog and Crimea, and nearby limestone, dolomite, and fire clay. Pop. (est. 1954), 600,000. C. C. H.

**The Region.** Stalino Oblast (Region), an administrative unit of the Ukrainian Soviet Socialist Republic, touches on the north coast of the Sea of Azov. The region is bounded by the Zaporozhye Oblast on the west, the Dnepropetrovsk Oblast on the northwest and north, the Kharkov Oblast on the north, the Voroshilovgrad Oblast on the east, and the Rostov Oblast on the southeast, while the Sea of Azov forms the entire southern boundary. Makeyevka, the so-called Ukrainian Magnitogorsk, is only about 12 mi. northeast of Stalino. Another important city is Zhdanov, or Mariupol, a port on the Sea of Azov, which exports principally coal and ore. Pop. (est. 1954), 3,900,000. W. S. V.

**STALINOGORSK** [stʌlinɑgɔ'rsk], formerly Bobriki, an industrial city in the Moscow Region of the Russian Soviet Federated Socialist Republic, in the southwestern Soviet Union, 128 miles south of Moscow. It lies on a slope on the small Skhot River, a tributary of the Upa. Formerly an obscure village, the industrial city has developed since 1928 under the Soviet Five-Year Plans. Captured by the Germans on Nov. 26, 1941, it was recaptured shortly afterward by the Soviet forces. It is on a rail line from Moscow. It has chemical plants producing nitrogenous and phosphatic fertilizers, using local deposits of brown coal and phosphates. It also has an important electric power station, utilizing the brown coal of the area. Pop. (est. 1950), 125,000.
C. C. H.

**STALINSK** [sta'lɪnsk], formerly Kuznetsk, an industrial city in the Kemerovo Region of the Russian Soviet Federated Socialist Republic, in the south central Soviet Union, about 190 mi. southeast of Novosibirsk. It lies in a broad valley, at the confluence of the Tom and Kondoma rivers, in the hilly Kuznetsk coal area. The fort of Kuznetsk was established in 1618, but remained a small village even after coal mining began two centuries later. Because of the vast coal resources, a great steel mill was built at Stalinsk during the Five-Year Plans, and there was an intensification of coal and iron-ore mining in the area. From 1926 to 1939 the population increased over 4,000 per cent. A branch railway connects Stalinsk with the Trans-Siberian, and the Tom River is navigable below the city. The steel mill is one of the largest and most modern in the world and is the principal industry. Pop. (est. 1950), 275,000. C. C. H.

**STAMFORD,** a city in Fairfield Co., Conn., situated on Long Island Sound, 38 mi. southwest of New Haven and 33 mi. northeast of New York City. Stamford was settled in 1641 by a colony from New Haven on the site of an Indian village. It was incorporated as a borough in 1830 and as a city in 1894. The city's government is by a mayor and board of selectmen. Within Stamford, as well as in the surrounding area, are numerous small parks. Cumings Park, the largest, with approximately 95 acres, is situated on Long Island Sound and has 1,600 ft. of beach. The municipal yacht basin, which is located in the park, provides a safe harbor for scores of motor boats and yachts. Stamford, situated on the fringe of the metropolitan area, is a popular home for many people working in New York City. Shippan Point is one of the city's several beautiful residential districts. Commuter service and freight facilities are supplied by the New York, New Haven and Hartford Railroad. A major industrial center, Stamford has factories producing roller bearings, castings, chemicals, cosmetics, electrical appliances, lacquers, machinery, oil burners, precision instruments, plastics, rubber products, stoves, hardware, locks and tools. Pop. 1950, 74,293.

**STAMMERING.** *See* STUTTERING.

**STAMP, BARON JOSIAH CHARLES** (1880-1941), British economist and banker, was born in Bexley, Kent, June 21, 1880. At the age of sixteen he began his career as a clerk in the British inland revenue service, where he remained for 23 years, becoming one of the government's foremost tax experts. While still a clerk he studied at the University of London. At the outbreak of World War I he was elevated to an assistant secretaryship in the British Treasury, where his service proved so valuable that before the end of the war he had become chief financial adviser to Prime Minister David Lloyd George. In 1919 Stamp entered private business as managing director of a large chemical firm, meanwhile lecturing at various universities on economic and statistical subjects. He sat on a number of government commissions and had considerable influence on the British tax structure, a service for which he was knighted in 1922. In 1924 he was British representative on the German reparations commission in Paris which produced the Dawes Plan, and in a similar capacity five years later he helped draw up the Young Plan. He was a director of the Bank of England, and when World War II began he became chief economic adviser to the British wartime cabinet. He, his wife, and his eldest son were killed Apr. 16, 1941, in a German air raid on London.

Stamp wrote extensively. Among his best-known works are *British Incomes and Property* (1915), a statistical study of capital and income; *Fundamental Principles of Taxation* (1919); and *Wealth and Taxable Capacity* (1922). E. W.

**STAMP ACT OF 1765.** After the French and Indian War, the British government left about 10,000 soldiers permanently in the American colonies to defend the frontiers against the Indians, to assist in the enforcement of the acts of trade and navigation, and to police Americans generally. Since the costs of British government were much increased, it was decided to place part of the burden of supporting the troops on the Americans. It was announced that a stamp tax would be imposed on Americans unless they offered some other acceptable plan as a substitute. Since nothing satisfactory was proposed, the Stamp Tax was enacted by the British Parliament in 1765. It provided that all colonial newspapers, legal documents, and business papers must be stamped, the stamps to be paid for in specie. The proceeds would be spent in America to support the troops.

The Stamp Tax irritated two vocal and influential groups of Americans: the lawyers and the newspaper editors. The first important public opposition came from the Virginia legislature, which adopted a set of resolutions stating that only the Virginia legislature could tax Virginians, and that to give such power to any other legislature would be to destroy American freedom. Patrick Henry, a member of the Virginia legislature, urged adoption of the resolutions in a speech in which he said: "Caesar had his Brutus, Charles the First his Cromwell and George the Third may profit by their example. If this be treason, make the most of it." In the North many merchants agreed not to buy British goods until the act was repealed. Town meetings denounced it and renewed the cry of no taxation without representation. Then, on the call of Massachusetts, it was agreed to hold an intercolonial Congress (Stamp Act Congress). Meanwhile rioting took place in towns where the stamps were to be sold. In Boston, the political enemies of Thomas Hutchinson, the governor, wrecked his house. In New York, mobs attacked the houses of British officials. Everywhere men who had been appointed stamp salesmen were forced to resign. The result of these various actions and of the pressure of British merchants on Parliament was the repeal of the Stamp Act in 1766. M. Je.

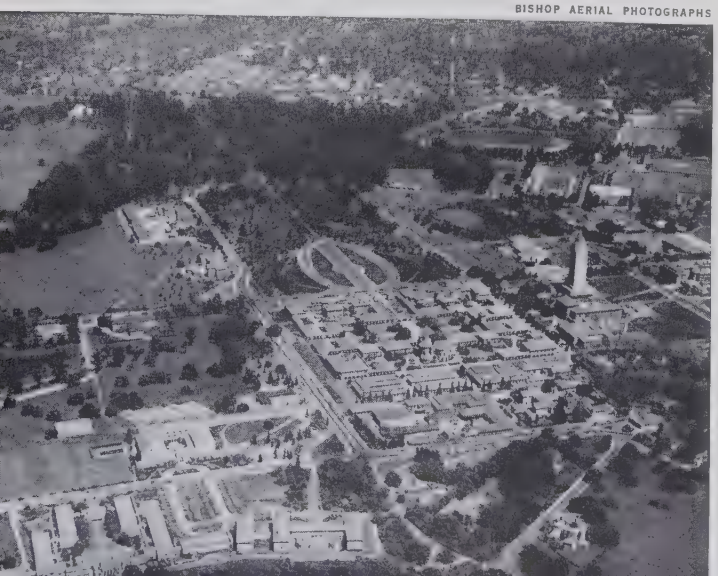
**STANDARDS OF MEASUREMENT.** *See* MEASUREMENTS, STANDARDS AND UNITS OF.

**STANDARD TIME.** *See* TIME.

**STANDISH, MYLES** or **MILES** (c.1584-1656), Pilgrim captain and Plymouth colonist, was born in Lancashire, England, about 1584. After serving in Queen Elizabeth's army in the Netherlands he joined the first company of the *Mayflower,* which landed at Plymouth, Mass., in 1620. He was appointed captain and became the colonists' mainstay in his friendly relations with the Indians, at times preventing Indian massacres and rebellions. In 1625, Standish was sent to England as an agent for the Pilgrims to negotiate with the Council for New England on supplies and the Pilgrims' rights in the new Plymouth Colony. He was fairly successful in his mission, returning in April 1626. In 1630 he became attorney for the Council for New England to aid the colonists in obtaining their lands under the new grant. In 1631 Standish and John Alden founded Duxbury, Mass., where he died on Oct. 3, 1656, at his estate "Captain's Hill." One of Standish's sons married a daughter of John Alden, the envoy in H. W. Longfellow's *Courtship of Miles Standish.* Standish, a brave soldier of great physical endurance, lived to see the population of Plymouth Colony grow to over 8,000. W. E. A.

*Air view of the campus at California's Stanford University. At the right center is the main quadrangle of university buildings; in the background the city of Palo Alto.*

BISHOP AERIAL PHOTOGRAPHS



**STANFORD, LELAND** (1824-1893), American railroad builder, governor, senator, and philanthropist, was born in Watervliet, N. Y., March 9, 1824. He was educated in the local schools, read law, was admitted to the bar in 1848, and began practice in Port Washington, Wis. Because of the loss of his law office and library by fire in 1852, Stanford moved to California, where several of his brothers were already established, and with their help engaged successfully in business. He was drawn to politics, became widely known in California, and was elected governor in 1861, serving until 1863. He then devoted his entire time to railroad construction and was president of the Central Pacific Railroad from 1861 until his death. On May 10, 1869, at Promontory Point, he drove in the gold spike joining the Central Pacific with the Union Pacific. He opposed public control of or interference with private railroad operations. Stanford was elected to the United States Senate in 1884, serving from March 1885 until his death. Aside from his business and political interests, he maintained extensive vineyards in Tehama County, Cal., and established a large ranch at Palo Alto where he bred and ran fine racing stock. His interest in education, and the untimely death of his son in 1884 at the age of fifteen, caused him to establish and endow Leland Stanford, Jr., University as a memorial. Stanford died in Palo Alto, Cal., June 21, 1893. T. R. H.

**STANFORD UNIVERSITY,** an accredited, coeducational, privately controlled institution. It is located on a campus of 1,500 acres at Stanford, Calif., in the Santa Clara Valley, 30 mi. southeast of San Francisco and 1 mi. from Palo Alto. Founded in 1885 as the Leland Stanford Junior University (still the legal name), the name has been shortened for all general purposes to Stanford University since about 1916. First instruction was given in 1891. The numerous divisions were founded as follows: School of Law, 1893; School of Medicine and School of Nursing, 1908; School of Education, 1917; Food Research Institute, 1921; School of Biological Sciences, 1922; Graduate School of Business, 1925; School of Engineering, 1925; School of Physical Sciences, 1926; School of Social Sciences, 1926; School of Humanities, 1941; Department of Physical Education and Athletics, 1945; and School of Mineral Sciences, 1947. The local chapter of Phi Beta Kappa was organized in 1904.

Degrees offered include the A.B. in liberal arts and the B.S. in engineering and in various types of engineering study. Professional and graduate degrees include the M.A., the M.S., the Ph.D., the M.B.A., the M.Ed., the D.Ed., the LL.B., the LL.M., and the M.D. Recently organized is the Stanford Research Institute, a nonprofit development established to provide, equip, and maintain laboratories and other experimental facilities for scientific and industrial research and to make them available to Stanford and other institutions and organizations for conduct of research and investigations. A Pacific-Asiatic-Russian studies program has been initiated by the School of Humanities, aided by a Rockefeller five-year grant and the action of the non-Communist Chinese government in providing a number of scholarships for American

students studying Chinese culture. A series of undergraduate regional majors has been established in the School of Humanities, covering Central Europe, France, and the Pacific-Asiatic-Russian areas. The library has available nearly one million volumes. Among the special collections featured are the Cubberley Library on Education; the Charlotte Ashley Felton Memorial Library of English and American literature; the Graduate School of Business Library; the Hoover Library on War, Revolution, and Peace; the Hopkins Transportation Library; and the Lane Medical Library. Collections dealing with Australia, Brazil, Greenland, and the French Revolution are of special interest. There is some scholarship aid offered and funds are available for student loans. Substantial fellowships in speech and drama have been established within recent years. Undergraduate women from outside the city who are not living with parents or guardians must live in the residence halls. Lower division men not living at home or working for their rooms elsewhere are required to live in residence halls for one year. Living quarters are also available at some of the fraternity houses. There are no sororities on the campus. *For statistics see* COLLEGES AND UNIVERSITIES. J. R. To.

**STANISLAVSKY** [stanisla'fsk3i], stage name of Konstantin Sergeyevich Alexeyev (1863-1938), Russian actor and producer, was born Jan. 17, 1863, in Moscow. Stanislavsky was a great actor and stage manager, the creator of a system of dramatic instruction based on natural laws of emotional, spiritual, and physical reactions, and founder, with V. I. Nemirovich-Danchenko, of the famous Moscow Art Theatre. His maternal grandmother was a French actress; his father, a wealthy Moscow industrialist of peasant antecedents, encouraged his children's musical and dramatic interests by building a private theatre in his home. Stanislavsky was a founder of the Society of Art and Literature, where he acted in and directed plays until the establishment of the Moscow Art Theatre (1898). A student of the principles of acting in Russia and abroad, especially in the practices of Shchepkin, Salvini, and the Meiningen Theatre, he evolved his own system of preparing plays and parts, which resulted in remarkable ensemble acting. He applied his acting principles to grand opera in his Opera Studio and School; moreover, he established three studios in the Moscow Art Theatre and set up other independent theatres, among them the Habbima Jewish Theatre. As an actor he created many notable roles in classic and modern plays. His hospitality to new ideas drew many distinguished foreign artists to the Art Theatre, such as Gordon Craig, who designed a production of *Hamlet,* and Alexander Moissi. Stanislavsky's ideas, recorded in two books, *My Life in Art* (1924) and *An Actor Prepares* (1937), have deeply influenced artists in many fields and countries. He died Aug. 7, 1938, in Moscow. *See also* RUSSIAN DRAMA (*Moscow Art Theatre*). E. R. H.

**STANLEY, SIR HENRY MORTON** (1841-1904), British explorer, was born at Denbigh, Wales, June 29, 1841, as John Rowlands. He was orphaned at the age of three, and at eighteen shipped as a cabin boy to New Orleans, where he was befriended by a merchant, Henry M. Stanley, whose name he adopted. He enlisted in the Confederate Army in 1861 and was captured at the Battle of Shiloh. In 1864 he enlisted in the Union Navy. As a newspaper correspondent he covered the Indian campaign of 1867, and in 1868 the New York *Herald* sent him with the British military expedition to Abyssinia. In 1869 he was commissioned by the *Herald's* proprietor, James Gordon Bennett, to search for the African explorer, David Livingstone. Starting out in March 1871, Stanley finally discovered the ailing Livingstone at Ujiji on Lake Tanganyika and nursed him back to health. In 1874 Stanley reported the British campaign against the Ashantis and then, taking up African exploration, made a survey of the shores of Victoria Nyanza and discovered the Kagera River, the most remote headstream of the Congo.

*SIR HENRY MORTON STANLEY*

COURTESY OF THE AMERICAN MUSEUM OF NATURAL HISTORY

In 1876 he descended the Congo River, from Nyangwe on the Lualaba River, crossed the Equator, and reached Boma at the mouth of the Congo in 1877. Between 1879 and 1884 he founded trading stations for King Leopold II of Belgium from Vivi to Stanley Falls on the Congo River, acquiring treaty rights from native chiefs to build roads through the cataract country. This exploration led to Belgian sovereignty over the Congo Free State. In 1888, he commanded an expedition for the relief of Emin Pasha, governor of the Egyptian Sudan. He discovered Mount Ruwenzori and traced the Semliki River to its source in Lake Edward in 1889. A repatriated British subject, Stanley entered Parliament in 1895 as a Liberal Unionist. He was the author of several accounts of his travels as well as of a study of the slavery problem. He died in London, May 10, 1904.

S. Van V.

**STANOVOI MOUNTAINS.** *See* DZHUGDZHUR.

**STANTON, EDWIN McMASTERS** (1814-1869), American lawyer and secretary of war, was born Dec. 19, 1814, at Steubenville, Ohio. His early education was interrupted by the death of his father in 1827, but he was admitted to Kenyon College, Ohio, in 1831. Spending only two years at Kenyon, he began to study law and was admitted to the bar in 1836. He was prosecuting attorney of Harrison County, Ohio, from 1837 to 1839. Stanton moved to Pittsburgh in 1847 and to Washington, D.C., in 1856. He remained both a Democrat and a Free-Soiler. In 1858 he was special counsel for the United States in cases involving land grants made by the Mexican government before the Mexican War. On Dec. 20, 1860, the date on which South Carolina seceded from the Union, Stanton became attorney-general of the United States under President James Buchanan. A strong Unionist, yet a Democrat, Stanton cooperated with Charles Sumner and W. H. Seward in exposing subversive activities, for which he was accused of betraying Buchanan. In 1861 he became legal adviser to President Abraham Lincoln's secretary of war, Simon Cameron, and on Jan. 20, 1862, himself became secretary of war, which office he filled with facility, although he had disputes

with Generals G. B. McClellan and U. S. Grant of the Union Army.

After Lincoln's assassination, President Andrew Johnson retained Stanton as secretary of war. Disagreeing with Johnson's policy of presidential control of Reconstruction, Stanton was asked by Johnson to resign his office, but Stanton, protected by the Tenure of Office Act, refused. Nevertheless, the failure of President Johnson's impeachment caused Stanton to resign on May 26, 1868. On Dec. 20, 1869, under President U. S. Grant, Stanton was appointed an associate justice of the United States Supreme Court, but he died on Dec. 24, 1869, in Washington, D.C. before he could take his seat. A Jacksonian Democrat, Stanton changed the policy of his party with his federalist convictions. He was an able administrator whose patriotic efforts were in large part responsible for the Union victory.

W. E. A.

**STAR, MORNING AND EVENING,** an expression applied only to the planets Mercury, Venus, Mars, Jupiter, and Saturn. A planet in this group is typically in the position of morning star when observable in the eastern sky before sunrise, and in the position of evening star when in the western sky after sunset. Strictly applied, Mercury or Venus is morning star from inferior conjunction to superior conjunction with the sun, and evening star from superior conjunction to inferior conjunction. Mars, Jupiter, and Saturn are morning stars from conjunction to opposition with the sun, and evening stars from opposition to conjunction.

H. S. R.

**STAR APPLE,** a tropical American tree, *Chrysophyllum cainito,* of the sapodilla family, widely cultivated in warm regions, both ornamentally and for its edible fruit. It is an evergreen reaching a height of 50 ft. The tree has oblong leaves, shiny above and covered below with a silky, golden-brown down. It bears purplish-white flowers. The smooth, globular, purple or light green fruit, as much as 4 in. in diameter, has 3 to 8 shiny seeds; in cross section, the core makes a star-shaped figure against the translucent white pulp.

J. C. Wis.

**STARA ZAGORA** [stɑ′rɑ zɑgɔ′rɑ], a city about 50 mi. northeast of Plovdiv in central Bulgaria at the southeastern edge of the Balkan Mountains. It is the capital of Stara-Zagora County. After the Russo-Turkish War of 1877-1878, in which the city was almost completely destroyed, it was rebuilt along modern lines. Some of Bulgaria's numerous mineral springs are found near the city, which is the market center for a productive agricultural area. The region is noted for its production of attar of roses. Under Turkish rule, it was important for its coarse woolen cloth, much of which was used by the Turkish army. Present products include vegetable oils, beer, and other beverages, food products, furniture, earthenware, and tanned leather. The city is an important railway junction for the Plovdiv-Burgas Railway and the line from Ruse or Ruschuk. Pop. 1946, 37,057.

E. St.

**STARCH,** a carbohydrate abundantly distributed throughout the plant kingdom. Its chemical formula is $(C_6H_{10}O_5)_n$, where $n$ is a large number, 500 or more.

**Sources.** Life, as we know it, could not exist without starch. It is the primary reservoir of solar energy, being produced in leaves from carbon dioxide by the aid of chlorophyll, and stored in roots, tubers, and seeds. Animal life derives a large portion of its food from the starch thus stored by vegetation. Potatoes and the cereal grains comprise an overwhelmingly large proportion of the food of the human race. Starch occurs in plants as small individual particles or grains, easily visible under low-power magnification. The starch from each species of cereal or tuber has a characteristic appearance or shape, the root-starch particles in general being larger than those of the grains. The principle sources of industrial starch are white potatoes in Europe and Indian corn in the United States. Other important sources of starch are sweet potatoes, cassava, wheat, and rice.

**Structure.** Experimental difficulties encountered in the study of carbohydrate polymers are responsible for a lack of definite knowledge concerning the structure of the starch molecule. However, persistent research has led to the view that starch is composed of two substances, both polymers of glucose. These components of starch have been called by various names, amylose and amylopectin or alpha-amylose and beta-amylose, and different investigators have reported wide variations in the relative amounts of each. One fraction, amylose, gives an intense blue color with iodine, a high yield of maltose on hydrolysis with beta-amylase, and has a marked tendency to retrograde. Its molecule is considered to be a long, unbranched chain consisting of from 100 to 300 *d*-glucopyranoside units connected by 1:4 alpha glucosidic linkages. The other component, amylopectin, gives a purple color with iodine and yields only about 60 per cent maltose on hydrolysis with beta-amylase, the remainder of the hydrolytic material being the so-called limit dextrins. This starch fraction is considered to have a more ramified or branching structure. Strong evidence has been advanced to show that this fraction of starch consists of units of 24 to 30 *d*-glucopyranoside residues connected by the normal 1:4 alpha-glucosidic linkages, while these units, in turn, are connected through 1:6 glucosidic linkages. The molecular weight of starch is in the order of magnitude of 100,000 or more. In the starch granule, however, it is clear that there must be many molecules held together by some little-understood chemical force.

**Properties and Types.** All starches are insoluble in cold water; but on heating, the grains swell and burst, forming a jelly, paste, or viscous liquid. It is to this property that many of the important industrial uses of starch are due, especially its use as an adhesive, and for sizing textile fibers and paper. Dry or acidified starch is converted into dextrin by roasting. When heated in water with acid, starch undergoes a series of changes, depending upon the amount of acid, temperature, and time of treatment. Mild heating with dilute acid causes no visible change in the microscopic appearance of the starch grains, but pastes subsequently made from this treated starch are of low viscosity. Such starch is called "thin-boiling" and finds much favor in the textile industry. Treatment in water at a higher temperature with a somewhat larger proportion of acid produces a dextrin paste, whereas more drastic treatment at a still higher temperature, usually under pressure, causes the starch to dissolve completely, forming a sweet-tasting, thin liquid, the dissolved material consisting of about equal parts of dextrin and sugars. When this liquor is refined and evaporated, a widely used product, known as confectioners' glucose or corn sirup, is obtained. When the amount of added acid is further increased and the pressure heating is prolonged, a still sweeter liquor is produced, which after refining and concentration results in a magma from which crystalline dextrose or corn sugar is obtained. Amylases, or starch-splitting enzymes, convert a starch paste into the soluble products, dextrin and the sugar, maltose. This reaction is

the basis of the grain-alcohol fermentation industry, where the source of the amylase is usually barley malt or a fungus grown on bran. The resulting maltose is then fermented by yeast or ethyl alcohol and carbon dioxide. A combination of mild acid liquefaction of starch followed by enzyme hydrolysis is employed to produce a type of corn sirup called sweetose, which contains less dextrin and more sugar and hence is sweeter than the older, standard type of corn sirup.

**Derivatives.** Starch can be readily oxidized. Mild oxidation with sodium hypochlorite produces a modified starch which forms a transparent paste and is widely used for paper sizing. More drastic oxidation, as with strong nitric acid, completely breaks down the molecule, forming saccharic acid, oxalic acid, carbon dioxide, and others. Starch may be nitrated to form nitrostarch, an explosive. Starch esters and ethers may readily be produced. These derivatives can be used for protective coatings or plastics but have found little industrial application.

**Uses.** In addition to its food value and its extensive employment in the manufacture of sirups and sugar, starch has an almost unbelievable number of uses in the industrial field. It is a raw product for the manufacture of alcohol, acetone, butanol, lactic acid, and other products of fermentation. The textile and paper industries consume great quantities of starch. Special laundry starches are a volume market, and other uses cover the field from cosmetics to explosives. J. K. D.

**STAR CHAMBER, COURT OF.** *See* ENGLAND AND WALES (*History*).

**STARFISH,** called also sea star, a common marine animal belonging to the class Asteroidea of the echinoderms, having no relationship or resemblance to fish. The sea stars are characterized by their five-rayed form and warty or spiny surface. They consist of a central disk from which radiate five arms broadly attached to the disk. Some sea stars have more than five arms, up to twenty or more, but five is the usual number. The body has distinct lower or oral, and upper or aboral, surfaces. The upper surface is usually provided with calcareous tubercles and short spines that are articulated to internal calcareous pieces, and it also has, in the angle between two of the rays, a small round perforated plate, the madreporite, through which water is admitted to the water-vascular system. The minute anus is in the center of the aboral surface. The oral surface, on which the animal creeps, has a central mouth from which radiate five grooves, one in each arm. In these grooves are the tube feet by which the animal moves. These feet are flexible tubular projections having terminal suckers, and are operated by water pressure conveyed in a system of canals; the whole mechanism is termed the water-vascular system. The digestive system is interesting. There are two superimposed stomach sacs in the disk; from the upper or pyloric sac radiate ten voluminous digestive glands, two in each arm. The food of common sea stars consists of various other animals, especially oysters and other bivalves. The sea star folds its arms over the bivalve, attaches its tube feet to the shells, and by exerting a pull, and probably by pouring out digestive secretions opens the victim. The lower stomach is everted into the oyster's shell, and digestion takes place by the secretions of the glands. The pabulum so obtained is taken into the interior, and as there is little need for further digestion, the intestinal part of the digestive tract is greatly reduced. Because sea stars are highly destructive to oyster beds, many efforts have been made to eradicate them, but no satisfactory method has been found. If sea stars are torn apart and thrown back in the water, they simply regenerate. Any part that includes a good piece of the disk is able to regenerate a new star. Sea stars reproduce by shedding eggs and sperm into the sea water. A free-swimming larva results that undergoes a process of metamorphosis in becoming a tiny sea star, which requires several years to grow to adult size. *See also* ECHINODERM. L. H. Hy.

COURTESY OF THE NEW YORK ZOOLOGICAL SOCIETY

*The common starfish, Asterias forbesi, a marine animal, usually five-armed, which feeds on clams and oysters*

**STARGAZER,** *Astroscopus guttatus,* a small, robust fish of the family Uranoscopidae with eyes located on top of the head. The head is large with an upturned mouth that is bordered by fringed lips. The stargazer lurks quietly on or partly buried in sand awaiting its prey. Capable of giving an electric shock, it is called, in some places, "electric toad." The electric organs are located in two quadrate-shaped areas that lie behind the eyes. A 6-in. fish gives a very noticeable shock. It perhaps serves as a protection from enemies and shocks small crustaceans and fishes upon which it feeds. A length of about 12 in. is average. About 15 species of this family are known from tropical and temperate seas. Some of the larger kinds are caught commercially as food. E. C. R.

**STAR GRASS,** *Hypoxis hirsuta,* a small herbaceous perennial of the amaryllis family having grasslike leaves. The 6-pointed, starlike, yellow flowers, greenish and hairy on the outside, bloom in groups of 1 to 6 and are lower than the tips of the leaves. A native of meadows and open woods from Kansas northward to Canada and eastward to the Atlantic, star grass can be grown in any rock or wild garden which is moist and partly shaded. J. C. Wis.

**STARK, JOHANNES** (1874- ), German physicist, was born in Schickenhof, Bavaria, on Apr. 15, 1874. He was named assistant at the University of Göttingen in 1900, taught in Hannover (1906-1909) and in Aachen (1909-1917), and was a professor at the University of Greifswald (1917-1920) and at Würzburg (1920-1921). He then retired and for many years did only occasional private teaching. In 1933 he was appointed president of the Physico-Technical Institute and of the German Research Association.

In 1905 Stark observed a Doppler effect in canal rays, for which he received the Baumgartner Prize of the Vienna Academy. In 1913 he discovered that spectral lines split under the influence of an electric field, a phenomenon analogous to the splitting of these lines in an electric field which Zeeman

observed in 1896. This discovery provided one of the clearest and strongest confirmations of the quantum theory of matter. For this work he was awarded the Nobel Prize in 1919. Cleavage in a magnetic field is now called the Stark effect.

Among Stark's many important technical books are *Electricity in Gases* (1902), *Principles of Atom Dynamics* (1910), and *Variations in the Structure and Spectrum of Chemical Atoms* (1920). He also founded the *Yearbook of Radioactivity and Electronics* which he edited from 1904 to 1919. After World War II Stark lived in Bavaria, in the United States zone of Germany. S. M. M.

**STARLING,** any one of a large number of species of medium-sized songbirds that together form the family Sturnidae. They are widely distributed in the temperate and tropical regions of the Old World, and one, the 8-in. *Sturnus vulgaris,* has been artificially introduced into the United States, where it has become abundant. The typical starlings

COURTESY OF THE U. S. FISH AND WILDLIFE SERVICE

*A starling carrying a may beetle to her young*

are characterized by a stout body, strong bill and feet, long, pointed wings, and a short tail. Their plumage may combine such dull colors as black, white, grays, and browns, or metallic blues, greens, and violets. Many species thrive best around human settlements. Almost all breed in holes in trees or in protected house areas, and during the rest of the year travel in flocks. They feed on insects, fruits, and grains. Their notes are loud and often melodious. Some species, especially the Asiatic grackles, are famous for their ability to imitate the human voice. H. G. De.

**STAR-OF-BETHLEHEM,** a genus, *Ornithogalum,* of the lily family having many species widely scattered in the Old World. These plants are bulbous perennials, reaching a height of 10 ft. Several tender species from South Africa are cultivated by florists. The name is especially used for *O. umbellatum,* a native of the Mediterranean region widely naturalized from old gardens. It has grasslike, basal leaves, and a slender flower stalk growing as high as 1 ft., which, in spring, bears clusters of starlike, white flowers striped with green, opening only in full sunshine.

J. C. Wis.

**STARS,** distant suns appearing as points of light on the night sky. Actually stars are immense spheres of incandescent gas existing in the depths of space in untold numbers and situated at unthinkable distances. They are cosmic powerhouses radiating prodigious energy. The sun is a star much like millions of others; but its comparative nearness to the earth causes it to seem large and almost blinding to the eye. Stars do not appear scattered evenly over the heavens, but are arranged in groups (constellations). These seem to preserve always the same configurations; yet the stars are really all in motion. Although the stars look as if placed on a great concave surface—the celestial sphere—they actually exist in a three- or four-dimensional universe; that is, they are at varying distances away, some comparatively near and others farther off by many light-years. Stars should not be confused with planets. At first glance, they cannot always be told apart; yet the planets move, day by day, on the sky. And they are other worlds like the earth, while the stars are hot, self-luminous bodies.

The extremes manifested in the stars are surprising, even though they are of the same basic pattern. The intrinsic brightness of certain stars turns out to be billions of times that of the faintest stars. The surface temperature range is from approximately 1,600° C., for "cool" stars, to a temperature of possibly 50,000° C. Stellar volumes and densities likewise present very excessive extremes, but the masses do not.

**Constellation, Atlases, and Catalogs.** The entire sky is divided into 89 sections, the area of each section comprising a constellation in the modern meaning of the term. There are north circumpolar, equatorial, and south circumpolar constellations, according to the observer's latitude. Around the ecliptic, there are 12 zodiacal constellations, which have been important historically and which have given their names to the 12 signs of the zodiac used in astrology. They are (in order eastward from the vernal equinox) Aries, Taurus, Gemini, Cancer, Leo, Virgo, Libra, Scorpius, Sagittarius, Capricornus, Aquarius, and Pisces.

Stars are designated chiefly in three ways: (1) by the technical name—the Greek letter followed by the genitive of the constellation, as $\alpha$ Leonis and $\beta$ Cygni, the method instituted by Johann Bayer in his *Uranometria* (1603), the first star atlas of much value, or by the number given by John Flamsteed, first Astronomer Royal of England, as 2 Canum Venaticorum; (2) by the catalog number, as Lalande 21185 and BD $+43°4305$; or (3) by the proper name, as Antares and Vega. A number of stars have all three designations. Only about 25 proper names are commonly in use; these include mostly the brightest stars. Other proper names are used by amateurs, whereas professional astronomers usually employ the Greek letter even for the brightest stars.

Various star atlases of practical value to students and especially observers have appeared since Bayer's. Norton's *Star Atlas* is one example of a modern small-scale chart, showing all naked-eye stars and many important objects, such as star clusters, nebulae, double and variable stars, co-ordinate systems, and circles. Charts on a larger scale become professional in type. The Beyer-Graff is a series on a larger scale (1 cm. $= 1°$), covering (in 27 charts) the northern sky and somewhat more; it records stars to magnitude 9.2. The Córdoba is another modern series of charts, and this covers the southern hemisphere. A famous chart is Friedrich Wilhelm August Argelander's *Durchmusterung* (Bonn, 1859-1862) of forty large sheets and reaching the 9th and 10th magnitudes; it covers the sky from the north pole to declination $-2°$, and the scale is 2 cm. $= 1°$; over 320,000 stars are shown. Although the stars were drawn from observations made with a small telescope, it is of great value.

Later, Eduard Schönfeld extended the series to declination −23°. The Franklin-Adams charts are a series of 206 photographic plates covering the whole sky, the scale being 1.5 cm. = 1°, and the magnitude reached being at least 14. The Wolf-Palissa is a series of photo charts along the ecliptic, the faintest magnitude being about 17. The unfinished *Carte du ciel* series of astrographic charts were planned in 1887 as an extensive international co-operative project involving eighteen observatories. The charts are made with large photographic refractors and are designed to show three million to four million stars when completed.

Star catalogs are a valuable asset to the astronomer. Commonly, the magnitude, right ascension, declination, precession, spectral type, and so on, are tabulated. Hipparchus is supposed to have made the earliest one, but no copies are extant. The *Almagest* of Ptolemy is the earliest one that has survived. The *Durchmusterung* of Argelander is the basis from which the charts for the atlas of the same name were drawn. Here, the stars are listed in zones for each degree of declination. The *Cape Photographic Durchmusterung* (1899) was the result of the efforts of David Gill, of the Cape Observatory at Capetown, who photographed nearly 500,000 stars, and Jacobus Cornelis Kapteyn of Groningen, who measured the plates. The work covers stars from −18° dec. to the south celestial pole. The *Henry Draper Catalogue,* compiled by Annie J. Cannon of the Harvard College Observatory, gives the visual and photographic magnitudes and spectral classes of 225,000 stars. Many other star catalogs exist, such as Sherburne Wesley Burnham's *General Catalogue of Double Stars,* Robert Grant Aitken's *General Catalogue of Double Stars* (1932), listing over 17,000 double stars with technical data on each, the Yale catalog of parallaxes by Frank Schlesinger, a standard reference for stellar parallax, and the work of Lewis Boss, *General Catalogue of 33,342 Stars* (1937), published by the Carnegie Institution. The unfinished *Astrographic Catalogue,* from which the *Carte du Ciel* is made, is very comprehensive, and will list several million stars.

## DISTANCES OF STARS

The stars are so far away that their known distances are almost unbelievable and in any case very difficult to comprehend. A model of the solar system on the scale of 1 ft.= 1 A.U. (astronomical unit or distance earth-to-sun) is a good working scheme to show all objects of the system conveniently. On this scale, Pluto would be 40 ft. from the sun. Inasmuch as the nearest star (α Centauri) is 270,000 A.U. distant, it would have to be 50 mi. from the sun in this model. This is only a beginning: to show the distance of the most remote stars belonging to our stellar system (the Milky Way), these stars would have to be of the order of 1,000,000 mi. from the sun, in the same model, inasmuch as some stars of the Milky Way are 20,000 times the distance of the nearest. Here, the model becomes unmanageable; nor have we yet represented the outer regions of space. Far beyond—many times as far—are the extragalactic nebulae, each with its unnumbered stars.

Distances of the nearer stars are measured by trigonometric methods of the surveyor, using a base line and measuring angles to the star. The base line of the diameter of the earth's orbit (186,000,000 mi.) is employed, although it is still too short for all but a few thousand stars. The exact position of a star is obtained by a series of measurements with the earth in one position, and the observation is repeated six months later with the earth on the opposite side of its orbit. The process is difficult and requires very high precision. Many negatives are required for one satisfactory parallax, besides the necessary calculation.

The heliocentric parallax is the maximum angle subtended at a star by the radius of the earth's orbit, the earth being at its mean distance from the sun. The farther away the star is, the smaller its parallax. The first measurements (about 1838) by Friedrich Wilhelm Bessel, at Königsberg, yielded the parallax of the star 61 Cygni. Later, parallaxes of Vega and α Centauri were obtained. Since then, the parallaxes of some 5,000 stars have been measured. The nineteenth-century work was extremely arduous because the heliometer or the filar micrometer was employed; but twentieth-century methods have used photographic technique, and certain observatories (as Allegheny, Leander McCormick, and Greenwich) specialize in parallax. The change of position relative to fainter, more distant, stars is all that can be observed. The faint background comparison stars are relatively so far away that their parallaxes do not record. Corrections are often needed, for sometimes the comparison stars show a slight parallax, or they may have a motion in space of their own; also, during the period of measurement, the entire solar system moves in space carrying the observer

TABLE I. THE NEAREST STARS

| *Star* | *Distance* | | *Apparent visual magnitude* | *Diameter (Sun=1)* | *Luminosity (Sun=1)* |
|---|---|---|---|---|---|
| | *Parallax* | *Light-years* | | | |
| | ″ | | m | | |
| Proxima Centauri (α Cen C) | 0.762 | 4.3 | 11.3 | 0.03 | 0.00004 |
| α Centauri A | 0.756 | 4.3 | 0.3 | 0.95 | 1.0 |
| α Centauri B | 0.756 | 4.3 | 1.7 | 0.82 | 0.3 |
| Barnard's Star (Oph) | 0.543 | 6.0 | 9.5 | 0.22 | 0.0004 |
| Wolf 359 (Leo) | 0.403 | 8.1 | 13.5 | 0.07 | 0.00002 |
| Lalande 21185 (UMa) | 0.388 | 8.4 | 7.5 | 0.46 | 0.005 |
| α Canis Majoris A (Sirius) | 0.376 | 8.7 | −1.5 | 1.69 | 21. |
| α Canis Majoris B (Sirius) | 0.376 | 8.7 | 8.5 | 0.02 | 0.0021 |
| Ross 154 (Sgr) | 0.350 | 9.3 | 10.5 | 0.21 | 0.0004 |
| Luyten 789-6 (Aqr) | 0.328 | 9.9 | 12.3 | 0.12 | 0.00008 |
| Ross 248 | 0.314 | 10.4 | 12.2 | 0.13 | 0.0001 |
| ε Eridani | 0.303 | 10.8 | 3.7 | 0.88 | 0.25 |

SOUTHERN MILKY WAY

*The famous "Coalsack" dark nebula is visible as a dark area near the center of the photo; and just to the right of, and slightly above, the dark area is the equally famous Southern Cross, formed by four stars (circled).*

The star $\alpha$ Centauri has a parallax of $0''.756$, and is the nearest "naked-eye" star to us. A faint companion to it, Proxima Centauri, has a parallax of $0''.762$; this is the largest known parallax, so that Proxima is our nearest star. The limit of reliable trigonometric parallaxes is around $0''.01$, which means that stars more remote than about 300 light-years cannot be measured by this method, and the distance must be found by other means.

**Units of Stellar Distance.** An astronomical unit is too small a unit for interstellar distances, so astronomers use the light-year and the parsec. A light-year is the distance light goes in a year, the value in miles being approximately 31,560,000 × 186,000 or 5.88 trillion miles. $\alpha$ Centauri, at a distance of 4.3 light-years is some 25,000,000,000,000 mi. away. The distance of a light-year represents about 63,300 A.U. Sometimes the parsec is used for very great distances. A star that had a parallax of $1''$ would be distant $206{,}265'' \div 63{,}300'' = 3.26$, or 3.26 light-years (the number 206,265 being the value of a radian, in seconds). No star known has such a large parallax. If $p$ represents a star's parallax, the distance in light-years is $3.26/p$; or in parsecs, $1/p$; or in astronomical units, $206{,}265/p$; or in miles, 5,880,000,000,000 × number of light-years.

## STELLAR LUMINOSITY

The sun's absolute visual magnitude is $+4.7$, and at the distance of 32.6 light-years it would look like a magnitude 5 star. Any star dimmer than the sun would be invisible to the unaided eye at the relatively small distance of 50 light-years. The sun, therefore, is but an average star; indeed a large majority of the stars we see are brighter than the sun. Consider an outer galaxy like the Great Nebula in Andromeda. We see, there, countless numbers of stars; but whatever stars of only the sun's luminosity are there, are invisible, being too dim to be seen from the solar system.

Some stars have but a small fraction of the sun's luminosity. The famous Barnard's Runaway Star is probably less than 0.0005 the sun's luminosity, and Proxima Centauri is only about 0.00007 as luminous as the sun. One of the very faintest known stars is van Biesbroeck's star of magnitude 18. It is 19 light-years distant, and of absolute magnitude 19.2; its luminosity is computed as around 1/550,000. Being 1/550,000 as bright as the sun, if placed at the sun's distance, it would not be much brighter than the full moon. But there are stars immensely brighter than the sun. Canopus, Rigel, and Deneb are each about 10,000 times as luminous as the sun. The notorious *S* Doradus, a star of magnitude 9 in the Greater Magellanic Cloud, has a luminosity 600,000 times the sun's. It has the greatest luminosity of any known star, although some of the supernovae may exceed it temporarily.

TABLE II. THE BRIGHTEST STARS

| *Star* | *Apparent visual magnitude* | *Approximate distance (light-years)* | *Luminosity (Sun=1)* |
|---|---|---|---|
| $\alpha$ Canis Majoris (Sirius) | $-1.^m58$ | 8.6 | 21 |
| $\alpha$ Carinae (Canopus) | −0.86 | 90 | 10,000 |
| $\alpha$ Centauri | +0.06 | 4.3 | 1.5 |
| $\alpha$ Lyrae (Vega) | 0.14 | 27 | 52 |
| $\alpha$ Aurigae (Capella) | 0.21 | 42 | 142 |
| $\alpha$ Boötis (Arcturus) | 0.24 | 32 | 94 |
| $\beta$ Orionis (Rigel) | 0.34 | 545 | 18,000 |
| $\alpha$ Canis Minoris (Procyon) | 0.48 | 11 | 6 |
| $\alpha$ Eridani (Achernar) | 0.60 | 70 | 248 |
| $\beta$ Centauri | 0.86 | 190 | 1,400 |
| $\alpha$ Aquilae (Altair) | 0.89 | 18 | 9 |
| $\alpha$ Orionis (Betelgeuse) | 0.92 | 300 | 2,600 |
| $\alpha$ Crucis | 1.05 | 150 | 1,700 |
| $\alpha$ Tauri (Aldebaran) | 1.06 | 55 | 126 |
| $\alpha$ Virginis (Spica) | 1.21 | 190 | 1,000 |
| $\beta$ Geminorum (Pollux) | 1.21 | 30 | 30 |
| $\alpha$ Scorpii (Antares) | 1.22 | 170 | 1,400 |
| $\alpha$ Piscis Austrini (Fomalhaut) | 1.29 | 27 | 13 |
| $\alpha$ Cygni (Deneb) | 1.33 | 465 | 10,000 |
| $\alpha$ Leonis (Regulus) | 1.34 | 70 | 143 |
| $\beta$ Crucis | 1.50 | 400 | 2,200 |
| $\alpha$ Geminorum (Castor) | 1.58 | 45 | 41 |

Giant and supergiant are terms referring to brilliance and not to size. Giants, like Arcturus, are far more luminous than ordinary stars, while supergiants, such as Antares, are exceedingly luminous. As the value of luminosity decreases, the relative number of stars of low luminosity increases rapidly; that is, for every supergiant there are many thousands of stars of the sun's intrinsic brightness, and hundreds of thousands of those of very low brightness. Although in a given region of the sky the low-luminosity stars are more numerous, yet the high-luminosity ones are more numerous as discerned with the unaided eye.

## STELLAR DIMENSIONS

Star diameters are important in stellar investigation. No star in the heavens is near enough to show any disk even in the largest telescopes, the stars exhibiting themselves only as points of light. It is possible to measure the angular diameters of a few stars with the stellar interferometer. The diameter in arc, together with the distance, gives the linear diameter in miles, although the accuracy depends upon the accuracy in the measurement of parallax for distance. At Mt. Wilson, Francis Gladheim Pease first measured the diameter of Betelgeuse with the 20-ft. interferometer. The diameter proved to be considerably larger than the earth's orbit. Only the largest stars can be measured, and they have been found to be 10 to over 400 times the sun's diameter.

The bright reddish and orange stars are the largest and are selected for measurement. All of those measured are vastly larger than the sun.

Diameters are also obtained indirectly by calculation from the observed color index and the absolute magnitude. Eclipsing binary stars sometimes have their size estimated, for the form of the light-curve of the star allows the diameters to be found in comparison to the mean distance of separation of the pair.

**Mass and Density.** The mass of a star, or quantity of matter contained, can be found directly only in the case of binary systems where the parallax and the orbit of the revolving pair are already observed. The combined masses of the two components are determined; but only in certain cases can the mass of a single component of the binary be found. The masses do not vary nearly as much as the size and temperature. Masses are seldom found over three times the sun's mass. For density of stars, the mean density is calculated, for the centers are surely far denser than regions near the surface. A wide range is exhibited. The red giant and supergiant stars are only about as dense as a laboratory vacuum, or considerably less than 0.001 the density of air. The low stellar densities grade into medium, then into high, and finally into incredibly great densities in the white-dwarf stars, like the companion of Sirius. The density of this star is calculated at 27,000 times that of the sun or about 40,000 times the density of water. While it has the mass of a star it is only the size of a planet, and 1 cu. in. of its average material if placed on the earth would weigh a ton. Even so, the star is held to be in the gaseous state and its atoms are thought to be completely ionized—that is, entirely stripped of their revolving electrons—and very closely packed. The surface temperatures of stars range from about 1,600° K, for the coolest or red stars to around 50,000° K for the hottest or blue stars. Thus, the temperatures change as one goes from one spectral class to another, and the color of the star appears to depend upon its temperature.

**Mass-luminosity Relation.** A simple law has been discovered for the relation between the mass and the luminosity of a star: the greater the mass, the more luminous the star is, and in fact a mass-luminosity curve can be drawn on which most of the stars fall. Stars of small mass (like Krüger 60 B), having little light-giving power, fall near the bottom of the curve, while Capella and other massive stars are near the top. The explanation appears to be that the massive stars develop a temperature higher than other stars, and the heat finds its way to the surface and is radiated away more rapidly than with a less massive star. The mass-luminosity curve is drawn to represent known stars, and is believed to hold for those whose masses or temperatures have not been measured. Many stellar distances are known, as well as the apparent magnitudes, hence their absolute magnitudes become known by formula; therefore, the masses can be estimated from the curve.

**Stellar Interiors.** Ordinary or nonvariable stars are believed to be in a balanced state of equilibrium, in which opposing forces are at work. One is the gravitative force attempting to pull all parts of the body toward the center. This is balanced by the gas pressure, caused by motion of the molecules of the star's substance, which tends to expand the star. Radiation pressure, or actual pressure of light, adds its effect to gas pressure. The hotter the star is, the greater the effect of gas and radiation pressures. According to theoretical physicists, the pressure from superincumbent gases, and the temperature also, increase greatly toward the center of a star. Recent estimates put the central temperature of the sun at 25,000,000° C. Red giant stars probably have a lesser temperature, but still a few million degrees, while at the other extreme Eddington believed the temperature at the center of a white-dwarf star may reach 1,000,000,000° C.

Table III. Largest Stars*

| *Star* | *Diameter* | | *Luminosity* (*Sun*=1) |
|---|---|---|---|
| | (*Sun*=1) | *Millions of miles* | |
| α Herculis | 800 | 690 | 1,900 |
| ο Ceti (Mira) | 460 | 400 | 180 |
| α Orionis (Betelgeuse) | 460 | 400 | 2,600 |
| α Scorpii (Antares) | 330 | 285 | 1,400 |
| β Pegasi | 115 | 100 | 500 |
| α Tauri (Aldebaran) | 40 | 35 | 126 |
| α Boötis (Arcturus) | 22 | 19 | 94 |
| α Aurigae (Capella) | 16 | 14 | 142 |

*Diameters difficult to measure and vary in different measurements; table only general guide. Besides the above, ζ Aurigae has been estimated as 200 to 300 times the sun's diameter and ε Aurigae as of the order of 3,000 times. The smallest white-dwarf star, L 886-6 Monocerotis, has a diameter of perhaps only 2,500 mi.

## STELLAR MOTIONS

The expression "fixed stars" is used because the various constellations appear to maintain the same configurations throughout time. Yet this is an illusion due to their immense distances. All the stars are in motion. Moreover they are at different distances from the earth; that is, any group making up part of a constellation really exists in three dimensions; if one were in the midst of a constellation one would then see its stars in various directions all around.

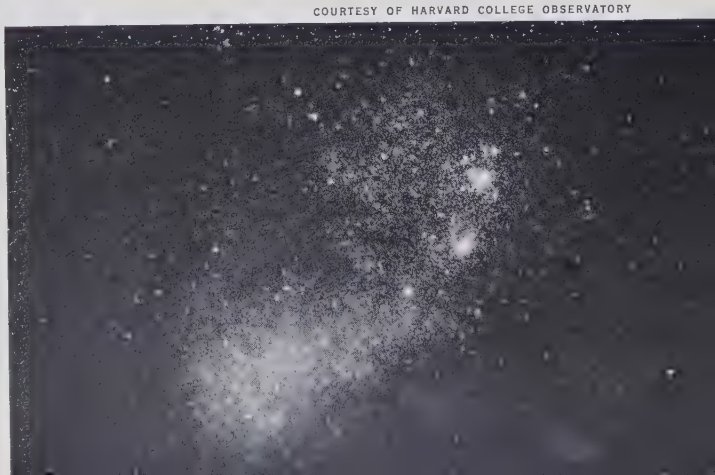
The daily rotation of the earth causes the stars to be forever rising in the east and setting in the west. The yearly revolution of the earth around the sun causes the stars to cross the meridian a bit earlier each day as the season advances. Exact observations of right ascension and declination of a star made at different times are found to vary. The change is accounted for partly by precession of the equinoxes (together with nutation) and aberration of starlight. Again, the annual parallactic motion, due to the earth's revolution, is also observable with the nearer stars. These motions are not real motions of the stars; that is, the stars have their own individual movements in space.

**Proper Motion.** The actual motion of a star, considered as angular measure on the celestial sphere from one point to

LESSER MAGELLANIC CLOUD

*A typical irregular extra-galactic nebula, or galaxy, in Tucana, near the south celestial pole. It shows no spiral but is resolvable into stars, star clusters, and nebulous clouds.*

COURTESY OF HARVARD COLLEGE OBSERVATORY



another, is its proper motion; it represents a displacement of the position between intervals of observation. Proper motion is always small, commonly only a few seconds of arc per hundred years. It is detected by comparing photographs (made at long intervals of time) under the blink microscope; or it may be determined by comparison of positions in star catalogs, and again the interval of comparison should be as long as possible for accuracy. The star having the largest proper motion is Barnard's Runaway star—discovered by Edward Emerson Barnard at Yerkes—the proper motion being 10″.25 per year. This motion is exceptional: the constellations would change in appearance during a person's lifetime, if all the stars moved as fast as Barnard's star. The magnitude of this star is 9.7; it is, therefore, invisible to the unaided eye; and the only bright stars with large proper motion are $\alpha$ Centauri and $\alpha$ Boötis (Arcturus). The bright stars, on the average, do not have proper motions over 0″.1 per year. Proper motion is not a full description of stellar motion; large proper motion means either fast actual motion, or that the star is relatively near the earth and shows its motion more quickly. Taking a large number of stars, one finds proper motion increases as the distance from the earth diminishes.

**Components of Stellar Motion.** Proper motion, alone, does not fully describe a star's movement, as it is but the change in apparent place. The actual motion in three-dimensional space is the space motion, resolvable into two components: radial velocity and cross motion (or tangential velocity). These components represent km./sec. or mi./sec., and the radial velocity is the measure of the motion toward or away from the observer, while the cross motion is simply a measure of the proper motion which is an angle measured in arc. This is the star's speed with respect to the solar system at right angles to the line of sight from the earth. Most stars move in all directions and so show both radial and cross motions, indicating that their motion is at an angle to the line of sight from the earth. Radial velocities are observed by means of the shift of spectral lines in the spectrograms, in accordance with the Doppler-Fizeau principle: a star going away from the earth has its spectral lines displaced toward the red end, and a star coming toward the earth has its lines displaced toward the violet end. The radial velocity is given a + sign when the star is moving away from the observer and a — sign when the velocity is toward the observer. Many stars are found to have radial velocities of 20 mi./sec., and some exhibit five times the speed. A correction (reduction to the sun) is applied to computed radial velocities, because of the earth's velocity in its orbit. The corrections establish radial motions with respect to the center of the solar system.

The actual motions of the stars in space, therefore, are found by means of proper motions (deduced by observations over long intervals), radial velocities (measured on spectrograms), and the distances (determined by the heliocentric parallaxes made by observations at opposite points in the earth's orbit). Commonly, the space velocities of stars are less than 30 mi./sec., being similar to planetary speeds. A few dozen move at 60 mi./sec., or more. Arcturus' space velocity of over 80 mi./sec. appears to be the highest of any of the bright stars.

**Moving Stellar Groups.** While the majority of individual stars have random movements, the moving star clusters have their members in motion in space with equal velocity and in parallel courses. The common space motion of the component stars is what identifies them. When one plots the space motions of a moving cluster, one is reminded of a meteor radiant. If the star cluster is moving toward the earth, the star paths lead away from a diverging point, while if the cluster is receding, the paths lead toward a converging point. The Taurus moving cluster contains over 100 stars and includes many of the Hyades stars, though Aldebaran is not a member. The proper motions of the Taurus cluster stars converge to a point near Betelgeuse. The convergence is a perspective effect, the actual space motions of the cluster members being parallel and equal. Their distance from the earth is about 130 light-years. The Ursa Major cluster is another moving stellar group whose 40 or more stars share a common motion and make an immense sphere 500 light-years in diameter. Except for $\alpha$ and $\eta$, the stars in the Big Dipper belong to this, together with several other bright stars scattered over the sky, namely, $\alpha$ Coronae, $\alpha$ Canis Majoris (Sirius), $\delta$ Leonis, $\beta$ Aurigae, $\beta$ Eridani, and others. It is curious that the sun happens to be inside this moving cluster temporarily, although it does not belong to the group. (In these open star clusters the stars are so far apart that other stars not of the group are often discovered moving through the group.) The Orion moving cluster is another, including various bright Orion stars (except Betelgeuse); and the Scorpius-Centaurus cluster is still another, at a much greater distance. The latter group includes a fine array of luminous southern stars, such as the Southern Cross, Antares, and so forth.

*H. V24 SPIRAL GALAXY IN COMA BERENICES, SEEN EDGEWISE*

**Rotation of the Galactic System.** The rotation of the galactic system is a type of stellar motion, as well as a motion of the sun and the earth. It is more difficult to prove that the Milky Way rotates than to prove planetary revolution, but it is being proved by modern methods. The conclusions arrived at have been reached by various means. In order to determine motion of the stars around the galactic center, one must observe stars which are very distant from the earth, those nearer the center of the system than the earth is, and those farther away. To observe the earth's local star cloud is of little use, because it, too, is in motion.

The center of the galaxy has been located by Harlow Shapley as being in the dense star clouds of Sagittarius. There is probably no great central star but there is a stellar concentration; this has the effect of causing the stars near the center to revolve faster than the outer stars.

The solar system appears to be located at a distance about two-thirds the way out from the center of the Milky Way at a distance of some 30,000 light-years. The entire galaxy of stars appears to be in rotation, in a clockwise direction as seen from the north galactic pole, that is, opposite to the direction of planetary revolution. The speed of revolution of the sun, the whole solar system, and the near-by stars, is about 200 mi./sec. (or somewhat less) around the galactic center, the present direction of motion being toward the constellation Cygnus. The period of galactic rotation (at the earth's distance) is some 200,000,000 years.

**Rotation of Stars.** In the case of the earth's own star (the sun), it is not difficult to observe the rotation time (25 days at the equator) by observing the progress of sunspots across the visible disk and by the Doppler shift in the spectroscope. But with the distant stars, no disk is observable and the problem is more difficult, though not insolvable. In a rotating star, the spectral lines of the light from the stellar limb turning away from the earth are shifted to the red end of the spectrum, and lines from the limb turning toward the earth, to the violet end. The total effect is thus a widening of the spectral lines of a star in rotation (unless the axis is directed toward the earth). Bluish *B* and *A* stars have equatorial rotation speeds up to nearly 200 mi./sec., or exceedingly fast compared to the sun; and Altair's rotation period is about ¼ of the earth's day. Some eclipsing binaries make known their rotation periods under special conditions, as one limb at a time is shown to the earth, the rest being in eclipse. Binary stars as a rule have high velocities of rotation.

## STAR CLUSTERS

These are groups of a dozen, a hundred, or thousands of stars that occur together in the sky. Star clusters are not an optical effect of all the stars being in the same line of sight, but are actually grouped together in space. They form one of the special objects of interest to telescope observers. Choice clusters, along with nebulae, colored double stars, and other celestial wonders, are given in observing lists in practical books on astronomy. The famous list of nebulae and clusters by Charles Messier includes a number (but by no means all) of the finest clusters. Johan Ludwig Emil Dreyer's *New General Catalogue* is an official source for thousands of star clusters, galactic nebulae, and outer galaxies. More recent lists are offered in observatory publications. The Pleiades, Hyades, and the Coma Berenices group are clusters resolved, in part, by the unaided eye. In the Pleiades, six stars are discernible by the eye alone, while several hundred of the group are revealed, along with the surrounding nebulosities, by long-exposure photographs with a large telescope or astrograph. Praesepe (the beehive cluster) and the double cluster *χ-h* Persei are examples of naked-eye clusters not resolved without optical aid.

**Open Clusters.** Open clusters belong to the earth's galactic system and are known, also, as galactic clusters. With low optical power, some exhibit only a few stars, but with larger telescopes most of them are shown to contain a few hundred and, some, a few thousand stars. Something over 300 are known to date, and there are likely many more not yet recognized. They often cover a space over 1° in diameter on the sky, and all are located near the plane of the Milky Way except for a few of the near-by ones, such as the Coma

COURTESY OF MT. WILSON OBSERVATORY

*MESSIER 13, GREAT STAR CLUSTER IN HERCULES*

*The finest globular cluster of the northern heavens. About 50,000 stars can be counted on a photographic negative; there are probably hundreds of thousands of other less bright stars in the cluster.*

cluster; that is, they seem to be arranged like the galactic stars, in a lens-shaped form. Variable stars are found practically lacking in this type of cluster, although some very luminous stars are found therein.

The Pleiades and the Hyades are the brightest open clusters; *χ-h* Persei and Praesepe also belong to this class. Distances of star clusters can be obtained only by indirect methods. The Hyades cluster is about 130 light-years away; the Coma group 260 light-years; and the Pleiades and Praesepe of the order of 500 light-years distant, whereas fainter open clusters extend to 15,000 light-years.

In the case of a number of the nearer clusters, the stars are quite widely scattered over the sky and are all moving as a unit. These are the moving clusters already described. Only by their similar motions can they be recognized as belonging to one cluster. An open cluster may be found moving through a group of other stars; or "interloper" stars may be moving through a cluster though not belonging to it.

**Globular Clusters.** Globular clusters are compact, spheroidal masses of many thousands of stars. Many offer a magnificent sight in a large telescope. The stars appear to be packed closely together but this is an illusion due to distance, although they do have a notable central condensation. Many are somewhat flattened, which implies rotation. Globular clusters lie outside the Milky Way plane and are most numerous in the great star clouds of Sagittarius, and in Ophiuchus. Any possible ones in the galactic plane are probably obscured by dust clouds and nebulous matter there. The globular clusters are arranged in a concentric manner with the galaxy, but they are not distributed evenly around the solar system, for the sun is not in the Milky Way's center. In this type of cluster, variable stars are found, to the extent of several hundred; they are the short-period cluster variables, of periods of about half an earth's day. Giant stars, supergiants, and the hot stars of the main-sequence abound in these clusters. Radial velocities determined for several globulars prove that the clusters are in rapid motion in space.

Only about 100 globular star clusters have been found in the galaxy. They are, therefore, relatively scarce, and this many are visible because of their bright stars. The brightest globular cluster is ω Centauri (NGC 5139), which appears like a hazy star of magnitude 4, though it is composed of innumerable stars of magnitude 12. The cluster 47 Tucanae is the next brightest. Both are southern objects and of singular beauty in the telescope. They are the nearest globulars, being about 20,000 light-years away. Messier 13 (NGC 6205) is the best one for northern observers. This and M 22 (NGC 6656 Sagittarii) are faintly seen with the unaided eye. The distance of M 13 is 34,000 light-years. Each contains some 60,000, and likely many more, stars of magnitude 13, and fainter. Other particularly good ones are M 55 Sagittarii, M 5 Serpentis, and M 3 Canum. Almost any globular has perhaps 50,000 stars which are observable, while near the center the stars are too concentrated to be discerned separately.

In the central densest parts of a cluster, the stars still have much room, though here the distances from one another become rather planetary than stellar. The central, condensed regions of globular clusters are about 15,000 light-years in diameter. The globulars are so far away that the earth's sun would be wholly invisible at their distances. The most remote globular found is NGC 2419, approximately 250,000 light-years distant. *See also* BINARY STARS; CONSTELLATIONS; GALAXIES; MILKY WAY; MULTIPLE STARS; NOVA; SOLAR SYSTEM; SPECTRA, STELLAR AND SOLAR; STELLAR MAGNITUDE; VARIABLE STARS. H. S. R.

**STAR-SPANGLED BANNER, THE.** The origin of the tune of the national anthem of the United States is unknown. It first appeared in 1775 as the song of the Anacreontic Society in London, an organization of wealthy music-lovers who met periodically to enjoy an orchestral concert, followed by a "cold collation" and some informal singing. Ralph Tomlinson, a lawyer from Lincoln's Inn and a president of the Society, wrote the words—*To Anacreon in Heaven.* These were first published in *The Vocal Magazine* in August 1778, and a sheet-music edition, with both words and music, was issued by Longman & Broderip in 1779. No composer is mentioned in any extant eighteenth century edition. Attempts have been made to assign the credit to Samuel Arnold, who conducted the Society's orchestra, and to John Stafford Smith, who published an arrangement for three voices in 1799, but it is much more probable that the tune had a prior existence—possibly a military one, since it has many characteristics of a trumpet march of the period—before the Anacreontic Society adapted it for their purposes and made it famous.

The earliest documentary proof of the presence of the song in the United States is the publication in New York newspapers in 1793 of a patriotic parody—*The genius of France from his star begem'd throne*—written to be sung to the tune. By 1795, the words of *To Anacreon in Heaven,* as well as other parodies, had begun to appear in American collections of songs, and to judge from the steady increase in such publications the melody gained rapidly in popularity, particularly at the elaborate town banquets held in each community to celebrate Washington's Birthday and the Fourth of July. At least a hundred patriotic parodies have survived. Francis Scott Key wrote his first poem to the tune in December 1805, and sang it himself at a dinner in Georgetown in honor of Stephen Decatur.

Key's more famous poem to the same tune was written later under the provocation of more stirring circumstances. Late in August 1814, the British had made a brief but successful sortie from their fleet in Chesapeake Bay, and had taken the city of Washington and burned a number of public buildings. On their way back to their ships, the British arrested a Dr. Beanes of Upper Marlborough for some offence which they counted treachery. Key had considerable political influence in Washington, and Dr. Beanes's friends persuaded him to undertake a trip to the British fleet to gain Beanes's release. Key left Washington for Baltimore on September 3, and together with Col. John S. Skinner, the United States cartel agent, set sail down the Bay on an unidentified sloop owned by one Benjamin Ferguson. The sloop caught up with the British fleet off the mouth of the Potomac on September 7. Dr. Beanes's release was finally agreed upon, but since the British had discussed their plans of attacking Baltimore in front of Key and Skinner the American party was detained for fear they might give warning to their countrymen. The whole fleet started north on the 8th, and was sighted off Baltimore on Sunday morning, September 11. During the following night, British troops were landed on North Point for a flank attack on the city, and the next day the smaller bombers and rocket ships were worked up the mouth of the Patapsco River for a frontal attack on Fort McHenry. Key, Skinner, Beanes, and their crew of eleven were returned to Ferguson's sloop under guard. During the day and evening of the 13th, the British bomb-ships stayed for the most part out of range of the small cannon of the Fort, and easily lobbed some 1800 bombs into and around the enclosure. When the firing ceased, around one o'clock in the morning of the 14th, tension increased on the sloop, since those on board had no way of telling whether the silence meant that the Fort had fallen, and it was only when they could finally see through the mist and drizzle of the morning that the over-sized flag on the Fort was still flying that they realized their fears were unfounded. Actually, the British had no desire to risk a serious engagement, since their orders from London directed them to attack New Orleans, not cities on the eastern seaboard, and when they discovered how well prepared Baltimore actually was they started re-embarking their troops from North Point during the night. When Key saw that the attack was over and the danger passed, he was stirred by a poetic impulse, and on the back of a letter he found in his pocket he started sketching his verses. The sloop was allowed to land in Baltimore that evening, and in his hotel Key wrote out a clean copy of his poem. It is probable that this manuscript is the one which is now preserved in the Walters Art Gallery in Baltimore. The next morning, Col. Skinner called upon Key and persuaded him to go to the offices of the Baltimore *American,* where the poem was set up in handbill form. In less than a week it had been reprinted in two Baltimore papers, and, not much more than a month later, a sheet-music edition was published by Joseph Carr with a musical setting arranged by Carr's son, Thomas. Other newspapers around the country picked up the stirring words from the Baltimore papers and, before the year was out, the song had also been included in *The Analectic Magazine* and three popular song books.

The melody was already common property, and it was not long before Key's words were generally recognized as the best embodiment of the American ideas of patriotism in song form which the country had produced. Apparently, during these earlier years, the populace was undeterred by the rather wide range of the melody, and it was constantly published in songsters side by side with the latest minstrel jig and theatrical hit. No other patriotic song appears so regularly and over such a long period, and therefore its final elevation to the position of national anthem seems to be

justified by this extended popular acclamation. Army and Navy regulations began to require its use in the 1890's, when circumstances called for the performance of a national anthem, and President Woodrow Wilson confirmed this usage during World War I in approving a new edition of the regulations. Congress, however, allowed a whole series of bills on the subject to die in committee, until finally the Seventy-First Congress passed Public Law 823 (U.S. Code 36, sec. 144), and President Hoover signed the bill on March 3, 1931, making the song the national anthem. The complete bill reads:

> *Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled,* That the composition consisting of the words and music known as The Star-Spangled Banner is designated the national anthem of the United States of America.

Neither this nor subsequent legislation defines which words or which music should be used, and since countless corruptions of the words and innumerable variations in the melody and harmony exist, we still do not have an "official version" of the anthem. R. S. H.

**STAR THISTLE,** a large genus, *Centaurea,* having flower heads surrounded sometimes by a starlike arrangement of spiny bristles. These plants are annual or perennial herbs of the family Compositae, mostly native to the Old World. The purple-flowered *C. calcitrapa* and the yellow-flowered *C. solstitialis,* both of which have stout spines radiating from the dense flower heads, and several other species are naturalized as weeds in North America. The American star thistle, *C. americana,* of the southwestern United States and Mexico, has showy pinkish flowers and grows nearly 6 ft. high. J. C. Wis.

**STAS, JEAN SERVAIS** [sta's] (1813-1891), Belgian chemist, famous for his precise determinations of the atomic weights of elements, was born in Louvain, Aug. 21, 1813. In 1840 he became professor of chemistry at the Ecole Royale Militaire at Brussels, and in 1865 was appointed to an important post in the Belgian mint. He resigned in 1872 and lived in retirement until his death nineteen years later.

Stas forms the middle link between Dumas, with whom he worked, and Theodore William Richards—a chain of great scientists who carefully determined the atomic weights of many elements. Their work has shown the finest technique ever achieved in the field of quantitative analysis. When Stas commenced his work, which extended to the determination of the atomic weights of many important elements, he had accepted William Prout's hypothesis that the weights of all elements were multiples of that of hydrogen. As his investigations progressed, however, he found the hypothesis partly disproved, for example, by the fact that the atomic weight of chlorine was 35.5 and not a multiple of 1. Dumas and Stas also investigated the action of potash upon various alcohols and ethers and proved that all true alcohols may produce corresponding acids. In 1850, while working on a poison gas, Stas devised a method for detecting vegetable alkaloids that is still widely used by toxicologists. In 1885 Stas was awarded the Davy medal of the Royal Society for his researches. He is said to have exemplified the "maximum of human patience" in his scientific work. His first paper on the atomic weights of ten elements (1850) was followed by his *Recherches sur les rapports reciproques des poids atomiques* and *Nouvelles recherches sur les lois des proportions chemiques.* Stas died in Brussels on Dec. 13, 1891. H. N. A.

**STASSEN, HAROLD EDWARD** (1907- ), American politician and educator, was born at West St. Paul, Minn., on Apr. 13, 1907. He received his early education in the local country schools and in St. Paul, and was graduated from the University of Minnesota in 1927 where he received his law degree two years later. He began practicing law in South St. Paul, Minn., and from 1930 to 1938 was county attorney of Dakota County. In 1938, he was elected governor of Minnesota, the youngest ever elevated to that office in the United States, and was re-elected in 1940 and 1942. Stassen had campaigned for office on a platform promising a liberal brand of legislation and economy in state government. In 1943, Stassen resigned his post as governor to join the United States Navy, and was assigned to duty in the Pacific area where he served as fleet flag officer on the staff of Admiral William F. Halsey. In 1944, he was appointed assistant chief of staff. In 1945, he was recalled from the Pacific by President Roosevelt and appointed United States delegate to the San Francisco meeting that wrote the charter of the United Nations. Resuming his law practice in Minneapolis, he entered actively into national politics, and was a leading candidate for the Republican presidential nomination in 1948 and 1952. He was appointed president of the University of Pennsylvania in July 1948, serving until his resignation in 1953. In 1952 he worked as political strategist for Dwight D. Eisenhower's successful campaign for the Presidency, in recognition for which Stassen was named Mutual Security Director in the new administration. In this capacity he visited Europe and the Near East during 1953, and the following year made an inspection trip to the Far East. He also became director of the Foreign Operations Administration in August 1953.

**STATE.** *See* CHURCH AND STATE; GOVERNMENT; POLITICAL SCIENCE AND PHILOSOPHY.

**STATE, DEPARTMENT OF,** an administrative department of the United States Government, first established as the Department of Foreign Affairs in July 1789 but given its present title two months later. At this time Congress invested the department with certain domestic functions; but these are of relatively minor importance, almost all of the department's activities having to do with the policy of the United States toward foreign countries or toward international organizations, for example, the United Nations. Major decisions as to foreign policy may be made directly by the President; but all the detailed work of implementing foreign policy, of making day-to-day decisions on foreign relations, of carrying on diplomatic and consular intercourse and formal negotiations with foreign governments, and of fostering national interests abroad devolves upon the department. The advance of the United States as a world power has augmented the variety and scope of these basic responsibilities, and the department has added, or expanded, its duties to include communication and intelligence services, the dissemination of cultural and information programs, and sundry activities having to do with international commercial and fiscal policy.

Operations of the department are distributed among nineteen separate offices, the heads of which clear through one of eight assistant secretaries or one of three special assistants. These officials, in turn, are responsible to the Under Secretary of State and to the Secretary of State, the latter being immediately responsible to the President for all departmental affairs. In 1952 the United States maintained 59 embassies and 14 legations.

Departmental personnel at home and abroad constitute the Foreign Service of the United States. Certain of the career personnel, including secretaries and counselors of legations and embassies, attachés, and the various grades of consul, are designated Foreign Service Officers. Under legislation enacted in 1924 and 1946, these are given professional status as to grade, compensation, promotion and tenure.

Because the Department of State is the oldest and, therefore, the senior department of the government, the Secretary of State is the ranking member of the President's cabinet. Under the Presidential Succession Act of 1886, the Secretary of State was the first in line of succession to the Presidency if that office should become vacant at a time when there was no Vice-President. This line of succession was modified by the Presidential Succession Act of 1947, which placed the Secretary of State after the Speaker of the House of Representatives and the President pro tempore of the Senate in the order of succession. A. J. Z.

**STATE AID.** *See* Public Finance (*Governmental Revenues and Other Receipts*).

**STATE COLLEGE,** an educational borough in central Pennsylvania, in Centre Co., situated 40 mi. northeast of Altoona. Coal is a natural resource of the region, and many caves are found in the surrounding area. The borough was founded and incorporated in 1875. Before this, Pennsylvania State College was founded in 1855, and the community derived its name from the college. A council and a borough manager administer the community, whose economic life is largely dependent upon the activities of the college. However, there are poultry, dairy, and grain farms in the area. Transportation is afforded by the Bellefonte Central Railroad and the All American Airways. Pop. 1950, 17,227.

**STATE GOVERNMENT,** the basic political unit in the federal system of the United States. According to this system, the governmental powers are constitutionally divided on a territorial basis between a central government, on the one hand, and smaller component units, on the other. The states are welded into national unity by the Constitution of the United States. No formal change may be made in this fundamental law of the land without the approval of three fourths of the states, expressed either through their state legislatures, or through conventions held in three fourths of the states. The Congress of the United States selects the particular method of approval.

**Delegated Powers.** Under the division of powers in the federal system of the United States, certain specific powers are delegated to the national government, certain powers are expressly denied to the states, and all others "are reserved to the states respectively or to the people." In a strict legal sense, therefore, the national and state governments are coordinate; neither is subordinate to the other, and neither can destroy or alter the powers of the other.

**Centralization.** This constitutional formula, however, has not always proved successful in actual practice. The first, and perhaps most important, reason for this failure is the constitutional provision that, in case of conflict between the asserted powers of the national government and those of the states, the former shall prevail as the "supreme law of the land." The application of this principle in the environment of a rapidly expanding economy and changing social structure has profoundly altered the practical position of the states in the federal system of the country. This change is commonly designated as governmental centralization, which may be briefly defined as the shift of influence and power from a lower to a higher level of government. For many years such a shift has been taking place in the United States, the general effect of which has been to transfer power and responsibility from the states to the national government. The roots of the widespread centralization of the twentieth century are imbedded in the industrial changes of the early nineteenth century. The vast transformation in the social structure and in the economic life, which grew out of these changes, furnished the basis for the steady advancement of centralization since the Civil War. Many have decried this growing encroachment upon states' rights for one reason or another, but not one has been able to restrain it.

Although further centralization may be expected, there seems to be no immediate danger that the forty-eight commonwealth governments will not continue as important units of the Federal Government.

**State Powers.** From the points of view of its relation to the individual citizen and the community, its fundamental position in the federal system of the United States Government, and the contribution of the states as laboratories for political experimentation, it would be difficult to overemphasize the importance of state government. The states have the power to make and alter their own institutions of government, subject to the constitutional requirement that they be republican in form; the power to regulate the suffrage in Federal as well as state elections, subject to the Fifteenth and Nineteenth Amendments to the Constitution; the power to levy and collect taxes, except upon instruments of the Federal Government and interstate and foreign commerce; the power to make and enforce police regulations of all kinds, subject to the due process and equal protection clauses of the Fourteenth Amendment; the power to promote the welfare of its people by fostering and promoting education, public health, agriculture, conservation of natural resources, and by supplying many other services; the power to deal with the whole field of private law regulating the relationship of man to man, and involving the family, the system of private property, and other institutions of modern civilization.

**Uniform Pattern of State Government.** There is a striking uniformity in the structure of state government throughout the United States. Each of the states, except Nebraska, has a bicameral, or two-chambered, legislature, and each has an independent executive, the governor. All of them have a more or less complicated system of courts, the judges of which are, in most cases, elected by popular vote. The governor and a varying number of other executive officers are elected by popular vote. In nearly all of the states, constitutional amendments may not be adopted without the approval of the electorate; in a considerable number of states, amendments may be initiated directly by the voters, and may later be ratified by them, without the participation of the legislature or a convention. Thus, the powers of the electorate are more numerous, if not more effective, than in the national government.

**Constitutional History.** The development of state governments has been marked by an early distrust of the executive, a later strengthening of the executive and judicial branches at the expense of the legislative, and an increasing popular control over all branches of the government. The framers of most of the first state constitutions were chiefly concerned with making the legislature supreme. Their previous unhappy experience with irresponsible colonial governors appointed from England was too fresh in their memories to permit more than a formal declaration of the avowed prin-

ciple of the separation of powers. As the legislature declined in popular esteem and confidence and the governor gained in political influence and power, through popular election and in other ways, about the middle of the nineteenth century this situation was reversed and the governor became the real legislative leader of the state. Despite separation-of-powers clauses in state constitutions which provide that the legislative, executive, and judicial departments shall be separate and distinct, these same constitutions vest important legislative powers in the governor.

The governor is elected by popular vote in all the states, and he exercises both executive and legislative powers. In most of the states, the judicial power of pardon is also vested in the governor, either in him alone or jointly in the governor and a board of pardons. In the majority of states, his legislative powers are more significant than his executive or administrative powers. The executive power of enforcing laws is shared with a varying number of other elected officials who owe no responsibility to the governor. Moreover, in many states, such powers of appointment and removal as he has are severely restricted. Thus his chief constitutional duty to "see that the laws of the State are faithfully executed" is in many instances more theoretical than actual.

Since about 1910, however, the voters have regarded with increasing approval the leadership of the governor in legislative matters, a development which led to a reorganization movement, beginning concretely with a somewhat dramatic reorganization of the administrative system of Illinois in 1917. In consequence, the governor has, with varying degrees of success, become head of the administration in a majority of the states. State government has accordingly come to revolve largely around the leadership of the governor in both legislation and administration, and the effectiveness of this leadership goes a long way toward determining the success or failure of state government.

The basis of the governor's participation in legislation is both constitutional and extraconstitutional. Among the legislative powers vested directly in the governor are the qualified veto power, which in thirty-nine states includes the power to veto items in appropriation bills; the power to send messages to the legislature with recommendations for the adoption of his legislative program; the power to call special sessions of the legislature for the consideration of urgent problems which, in the judgment of the governor, should not await the next regular session.

Of equal, if not greater, importance are those extraconstitutional influences which derive from the governor's position, as party leader and as exponent of public opinion.

G. W. Sp.

**STATE LEGISLATURE,** the legislative body provided by each of the forty-eight states of the United States by its constitution. These bodies are bicameral except in Nebraska, which adopted a unicameral form in 1937. The structure of the legislatures and their powers and duties are prescribed, and the legislative process partially regulated, by the state constitutions. There is no complete listing of their powers, since states, unlike the Federal Government, are said to have residual or reserved powers, and, hence, legislatures are able to do anything not forbidden by the state and Federal constitutions. Major fields of authority include: highways, education, health, welfare, state institutions, taxing, conservation of resources, regulation of utilities and other businesses, and criminal law. In the final analysis, state legislative powers are interpreted by state and Federal courts in cases in which the constitutionality of statutes is questioned.

In colonial days assemblies were regarded as the stronghold of popular liberties against royal governors and the English Parliament, and when these were swept away by revolution the people naturally set up state governments in which the legislature was predominant. The constitutional history of the states shows a gradual shift in power from the legislature toward that of the state courts and the executive branch headed by the governor. This shift in power has come through constitutional change, statutes, custom and usage, and court decisions.

The state legislatures vary as to structure, term, pay, procedure, and committee setup. The lower chamber, usually called the house of representatives, ranges from 35 members in Delaware to 399 in New Hampshire; the upper house, usually called the senate, ranges from 17 in Delaware and Nevada to 67 in Minnesota. The Nebraska legislature has 43 members. Population is the major basis of representation with the county widely used as the election district. Urban areas are commonly discriminated against in favor of rural areas. Districts are sometimes gerrymandered for party reasons. Terms in the lower house run from one to four years, with a two-year term usual; in the upper house the range is from two to four years with a majority of states having the four-year term. Regular sessions are held every two years in most states (generally in the odd-numbered years), limitations on the length of sessions being common. Compensation is usually small but runs as high as $5,000 per year.

The legislative power of both houses is equal, except that money bills must be introduced in the lower house. In most states the senate shares the executive power of appointment because of the power of confirming or rejecting the governor's nominees for department headships and other positions. The senate also tries impeachment cases brought by the lower house. The legislatures adopt rules of organization and procedure, which have evolved into an intricate pattern workable only by experienced members. Committees are used in every state to sift bills, hold public hearings thereon, and report their findings. Massachusetts, Maine, and Connecticut employ the joint committee system, thus saving the duplicate committee work which exists in most states. Legislative reference and bill-drafting services exist in a majority of states, and, beginning in Kansas in 1933, legislative councils have found favor in a number of commonwealths as an aid to planning legislation. Complex demands of modern legislative programs indicate the need for further reforms, including more effective control of lobbies, better office space and more adequate clerical services for committees, reorganization of the committee system, selection of legislative employees on the basis of merit rather than spoils, transfer of damage claims and private pension requests to an administrative agency, and more frequent legislative sessions with adequate advance planning. *See also* Legislative Council; Legislative Reference Bureau.

**STATEN ISLAND.** *See* New York; Richmond.

**STATESBORO** [ste′tsbʌ′ro], a city in east central Georgia, the county seat of Bulloch Co., located 50 mi. northwest of Savannah. Incorporated in 1866, Statesboro is administered by a mayor and council. Georgia Teachers College, a unit of the university system of Georgia, is located near by. Statesboro has transportation furnished by the Central of Georgia Railway. Situated in a farming district where peanuts are grown extensively, the city's main industry is concerned with peanut processing. The production of turpentine is also important. Pop. 1950, 6,097.

**STATES OF THE CHURCH** or **PAPAL STATES,** the name given to the territories in central Italy that were under the temporal rule of the Pope from 754 to 1870. The extent of the papal possessions varied in size from time to time; in 1859 just before the Austro-Italian War they embraced more than 16,000 sq. mi. and had a population of over 3,000,000. At that time they extended over the whole of central Italy and were bounded by the Lombardo-Venetian Kingdom on the northwest, by the Adriatic Sea on the northeast, by the Kingdom of Naples on the southeast, by the Mediterranean on the southwest, and on the west by the grand-duchy of Tuscany and the duchy of Modena. The Papal States also included Benevento and Pontecorvo. In present-day Italy these territories are now included in Latium, Umbria, Marche, and part of Emilia-Romagna.

At first, under the law of 321, which gave the Catholic Church power to hold and to transmit property, the papal possessions were the private property of the Church, which was in the same position as any other wealthy landowner. Full sovereignty is generally dated from 754 when the Frankish King Pepin, by the "Donation of Pepin," presented territory to the Pope and guaranteed the Pope in his possessions against the Lombards and the Byzantine Emperor. Under Charlemagne, Pope Adrian I was enabled to increase the territories to include almost the whole of central Italy. In turn, Charlemagne was crowned Holy Roman Emperor by Pope Leo III in 800.

For the next four centuries the difficulties of the Papal States came mostly from within. Various factions of the nobility in the city of Rome strove to acquire control of the papacy and its spiritual and temporal power. In the struggle the Pope was constantly forced to make sacrifices of territory and power to the Holy Roman Emperor in order to obtain protection against internal dangers. Papal power was restored under Pope Innocent III and in 1213, by a golden bull, the Emperor Frederick II confirmed the States of the Church as including the old Patrimony from Ceprano to Radicofani, the March of Ancona, the Duchy of Spoleto, the territories of Matilda, the County of Bertinoro south of Ravenna, the exarchate, and the Pentapolis. This settlement was jeopardized, however, by Frederick II and his successors. The defeat of the Hohenstaufen line confronted the States of the Church with even greater difficulties arising from the French. The next five hundred years saw a sharp decline in the power and extent of the States, culminating in the era of Napoleon. By the Congress of Vienna (1814-1815) the States were again re-established in their old boundaries except for Avignon and Venaissin and a narrow strip along the frontier of the Ferrara district north of the Po, which was given to Austria along with the right of garrisoning Ferrara and Comacchio. Many people living in the Italian peninsula, however, influenced by the ideas of the French Revolutionary and Napoleonic regimes, demanded national unification and a constitutional government. Their great enemy was Austria, and by its alliance with Austria, the Papacy continued to enrage the Italian liberals. The revolutions of 1848-1849 were generally unsuccessful, but thenceforth the Pope continued to remain in power only because he was protected by Austria and France. The establishment, in 1861, of the Kingdom of Italy over the protests of the Pope foreshadowed the end of the States of the Church. Effective power was now only in the hands of France; with the withdrawal of the French soldiers from Rome in 1870, troops from the Kingdom of Italy entered the city and the last remnants of the States of the Church were annexed to the Kingdom. The Pope excommunicated all parties who had a part in the occupation of the States of the Church and forbade Catholics to participate in Italian political life, but the possibility of the restoration of the States of the Church dimmed with the years. By the Law of Papal Guarantees of 1871 Italy sought to assure the Pope of his sovereignty of the Vatican, the Lateran, and Castel Gandolfo, but the Pope refused to accept or to recognize the act and shut himself up as the "Prisoner of the Vatican," appealing unavailingly for outside aid. Not until 1929, by the Lateran Treaty or Concordat, did the Pope recognize the accomplished fact of the destruction of the States of the Church. *See also* ITALY. S. J. H.

**STATES' RIGHTS,** a political doctrine in United States history, or the powers claimed under that doctrine. The Tenth Amendment to the Constitution declares: "The powers not delegated to the United States by the Constitution, nor prohibited by it to the States, are reserved to the States respectively, or to the people." Interpretation of this statement immediately divided political theorists into two schools: "Strict Constructionists," who construed the Amendment literally and narrowly; and "Loose Constructionists," who cited implied powers inhering in the Federal Government. The latter group, typified by Alexander Hamilton, formed the core of the emerging Federalist Party, dominated the first three administrations, and through John Marshall impregnated the formative decisions of the Supreme Court. The passage of the Alien and Sedition Acts in 1798 provoked an affirmation by the anti-Federalists (later called Democratic-Republicans, or Democrats) that the Constitution was a compact of states, each capable of judging and, if need be, rejecting Federal statutes. The statement of this position in the Kentucky and Virginia Resolutions of 1798-1799, drafted by Thomas Jefferson and James Madison, became the cornerstone of States' Rights.

The application of this doctrine was extremely varied, and its defenders and antagonists inconstant. Thus, Jefferson invoked the concept of implied powers to explain the purchase of Louisiana; the New England Federalists used the abandoned arguments of Jefferson at Hartford in 1814 to oppose the current war; and John C. Calhoun, an enthusiast for that war and for national as against sectional interests, became the spokesman for States' Rights when Andrew Jackson's tariff policy appeared to threaten the economy of South Carolina. Calhoun, Democrat, in 1828 challenged the authority of Jackson, another Democrat, by propounding the right of nullification, which led inexorably to the right of secession; while Webster, a Whig, supported Jackson on the inseparability of the Union in his famous debate with Hayne in 1830. Clearly those opposing and those defending States' Rights utilized the doctrine, not on its merits or demerits, but to support programs based on more cogent considerations.

States' Rights was long identified with the Democratic Party and the South, but in recent years Republicans have tended to champion state sovereignty on such issues as the use of tidelands oil. In the South, many defenders of the special institutions of the region have also returned to the States' Rights banner, to the point of forming a States' Rights Party. Its presidential candidate, J. Strom Thurmond, received 1,169,021 votes in 1948 and supported Republican candidates in 1952. *See also* DIXIECRATS. E. A.

**STATESVILLE,** a city in west central North Carolina, the county seat of Iredell Co., located north of the Catawba River, 41 mi. north of Charlotte, in an agricultural area where cotton, wheat, and corn are leading crops. Pine timber is

a natural resource of the region. Founded in 1750 by Scotch-Irish and Germans from Pennsylvania and Maryland and originally called Fourth Creek, Statesville was incorporated as a city about 1789. During the Civil War it was declared the temporary capital of the state by Governor Zeb Vance, following the fall of Raleigh. His home, the temporary state capitol, is a feature of historic interest. An unusual fact is that the entire city by official ordinance is a bird sanctuary. The Wallace Brothers Herbarium in Statesville contains a large collection of medicinal roots, herbs, and plants. The city is the seat of Mitchell College. Transportation is supplied by the Southern Railroad. Cotton yarn, cottonseed products, flour, feed, knitted fabrics, garments, bricks, and machinery for brickyards are leading manufactures. Pop. 1950, 16,901.

**STATE TAXES.** *See* TAXATION (*Types of Taxes*).

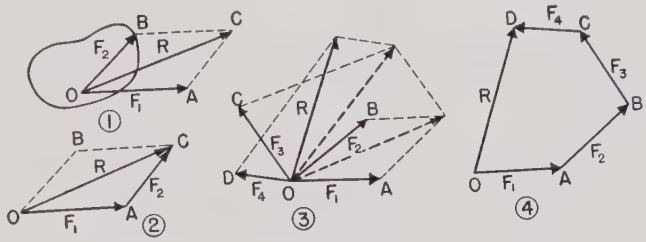
**STATICS** [stæ′tɪks], a branch of mechanics concerned with material bodies that remain at rest when subjected to the action of forces. Broadly speaking, it includes the theory of equilibrium of fluids and solids, but the accepted use of the term refers to a study of the equilibrium of rigid bodies and inextensible cords, belts, and chains. The theory of equilibrium of deformable solid bodies is in the province of the theories of elasticity and plasticity, and the equilibrium of liquids and gases is considered in fluid mechanics.

**Historical.** Statics is the oldest branch of mechanics, and some of its principles were doubtless understood by the Egyptians and Babylonians, as evidenced by the construction of pyramids and temples. Among the early contributors to the theory of statistics was Archimedes (c. 287-212 B.C.), who developed the theory of the lever and stated the basic law of hydrostatics. However, the structure of statics in its modern form stems from the work of Stevinus (1548-1620), who in 1586 stated the law of composition of forces, or parallelogram law, and employed it in the solution of a number of problems.

**Fundamental Principles.** The laws of statics follow from the general dynamical laws by considering the special case for which the velocities of the bodies vanish, but for historical and pedagogic reasons statics is frequently developed independently of dynamics on the basis of a certain set of postulates or principles. These are (*a*) the law of composition of forces, (*b*) the principle of equilibrium, and (*c*) the action and reaction principle. In dealing with rigid bodies, that is, ideal bodies which are not deformed when subjected to the action of forces, another principle, based on the concept of a rigid body, is introduced. This is the principle of transmissibility of force. This principle asserts that the state of a rigid body in equilibrium is not altered if the point of application of the force is shifted along the line of force action.

**Force as Vector.** It will suffice to consider force as an effort in the nature of a push or pull, having certain direction, magnitude, and a point of application. Mathematically, the force can be regarded as a vector, and hence it can be represented as a directed line segment whose length is a measure of the magnitude of the force. (To distinguish the vector quantities from other quantities which are characterized by the magnitude alone, vectors are printed in boldface type.)

**Parallelogram Law of Forces.** Consider a body (Fig. 1) subjected to the action of two forces $\boldsymbol{F}_1$ and $\boldsymbol{F}_2$ applied at some point $O$ of the body, which are represented in the figure by the directed line segments $\overrightarrow{OA}$ and $\overrightarrow{OB}$. It is suggested by experiments that the effect of the forces $\boldsymbol{F}_1$ and $\boldsymbol{F}_2$ is equivalent to the action of a single force $\boldsymbol{R}$ represented by the vector $\overrightarrow{OC}$. The magnitude of the vector $\boldsymbol{R}$ is equal to the length of the diagonal of the parallelogram constructed on vectors $\overrightarrow{OA}$ and $\overrightarrow{OB}$ as sides; its direction is shown in Fig. 1. The force $\boldsymbol{R}$ is called the resultant of the forces $\boldsymbol{F}_1$ and $\boldsymbol{F}_2$. Expressed in symbols, $\boldsymbol{R} = \boldsymbol{F}_1 + \boldsymbol{F}_2$, where the addition is understood to be in the geometric sense described above. This is the first principle of statics, known as the parallelogram law of forces.



*Figs. 1-4—Method of determining the resultant of two or more forces passing through a common point*

**Resultant Force.** Instead of constructing the parallelogram *OACB*, the direction and the magnitude of the resultant $\boldsymbol{R}$ can be obtained by constructing a triangle *OAC*, formed by shifting the vector $\boldsymbol{F}_2$ parallel to itself until the initial point $O$ of the vector $\overrightarrow{OB}$ coincides with the terminal point $A$ of the vector $\overrightarrow{OA}$. Clearly, the closing side of the triangle *OAC* has the length of the direction of the vector $\boldsymbol{R}$ (Fig. 2). This procedure of obtaining the resultant can be generalized in an obvious way to obtain the resultant of a system of forces $\boldsymbol{F}_1, \boldsymbol{F}_2, \ldots, \boldsymbol{F}_n$, all of which are applied at the same point $O$ of the body. Thus, if the system consists of four forces shown in Fig. 3, one can obtain the resultant of the forces $\boldsymbol{F}_1$ and $\boldsymbol{F}_2$, add this result to the force $\boldsymbol{F}_3$, and so on, to obtain the resultant $\boldsymbol{R}$. The resultant $\boldsymbol{R}$ found graphically is represented by the closing side of the force polygon *OABCD* (Fig. 4).

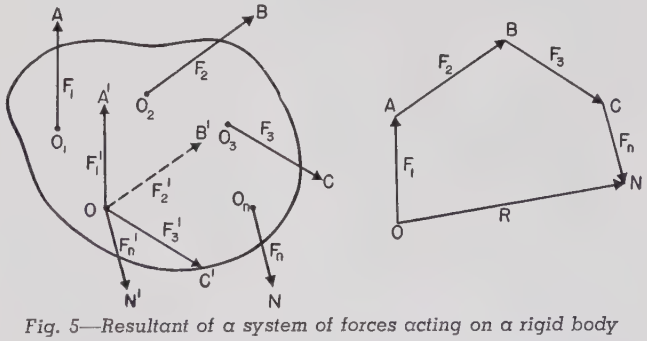


*Fig. 5—Resultant of a system of forces acting on a rigid body*

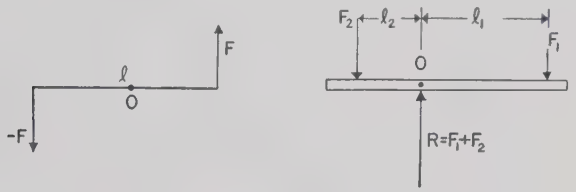
The definition of the resultant force will be extended to a system of forces $\boldsymbol{F}_1, \boldsymbol{F}_2, \ldots, \boldsymbol{F}_n$, acting on a rigid body, and having different points of application, $O_1\ O_2, \ldots, O_n$. A point $O$, called the point of reduction, is chosen, and there a system of concurrent forces is constructed whose directions and magnitudes are the same as those of $\boldsymbol{F}_1, \boldsymbol{F}_2, \ldots, \boldsymbol{F}_n$. The resultant $\boldsymbol{R}$ of these concurrent vectors, that is, the vector represented by the closing side of the polygon of forces, is called the resultant force acting on the body (Fig. 5). Clearly, the vector $\boldsymbol{R}$ does not depend on the choice of the point of reduction. If the length of the vector $\boldsymbol{R}$ is not zero, the body cannot remain at rest. For, in accordance with Newton's second law of motion, any body acted on by an unbalanced force will move with an accelerated motion. It follows that a

necessary condition for equilibrium of a body is that the resultant of all forces applied to the body vanish. This condition, however, is not sufficient; that is, the resultant of applied forces may vanish, and yet the body may not be at rest.

As a simple, important illustration of this circumstance consider a thin, rigid rod of length $l$ whose weight is negligible in comparison with the magnitude of the forces applied

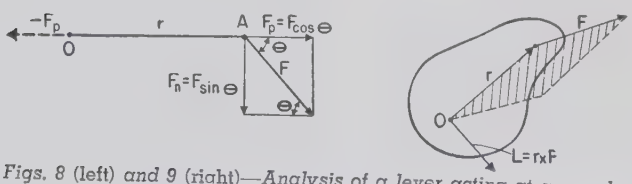


*Figs. 6* (left) *and 7* (right)—*Illustration of a couple, and of a lever, respectively*

to it. Let this rod be subjected to a pair of forces $\boldsymbol{F}$ and $-\boldsymbol{F}$ equal in magnitude and opposite in direction, and applied at the ends of the rod as shown in Fig. 6. The resultant $\boldsymbol{R}$ in this case is $\boldsymbol{F} - \boldsymbol{F} = 0$, but the rod will not be in equilibrium. It is clearly evident that it will turn about the mid-point $O$ of the rod. A system of two equal and oppositely directed forces, not acting in the same straight line, forms a couple, the magnitude of which can be taken as the product of the magnitude of $\boldsymbol{F}$ by the length of $l$ of the lever arm. The significance of this choice of measure can be seen from the following considerations, which illustrate the principle of the lever as deduced by Archimedes and which give rise to a condition of rotational equilibrium. Consider a light, uniform, rigid rod pivoted at the point $O$, subjected to the action of the force $\boldsymbol{F}_1$ applied at a distance $l_1$ from the pivot, as shown in Fig. 7. Under the action of the force $\boldsymbol{F}_1$ the rod will turn about the point $O$. It is suggested by direct experiments that the rotation of such a rod may be prevented by applying a force $\boldsymbol{F}_2$ at a distance $l_2$ from the pivot, of such a magnitude that $F_2\, l_2 = F_1 l_1$.

The number of ways in which the rotation may be prevented is infinite, and the essential thing is to choose the forces $\boldsymbol{F}$ and the points of application so that the product of the lever arm $l$ and $\boldsymbol{F}$ is equal to $F_1 l_1$. This statement embodies the law of the lever.

The equilibrium of the system is readily explained. The action of the forces $\boldsymbol{F}_1$ and $\boldsymbol{F}_2$ on the pivot gives rise to a reaction force $\boldsymbol{R}$, acting on the pivot at $O$ and directed oppositely to the forces $\boldsymbol{F}_1$ and $\boldsymbol{F}_2$. In accordance with the action-reaction principle in mechanics, the magnitude of $\boldsymbol{R}$ is equal to the sum $\boldsymbol{F}_1 + \boldsymbol{F}_2$. Thus the resultant of all forces acting on the system $\boldsymbol{F}_1 + \boldsymbol{F}_2 + \boldsymbol{R} = 0$, so that the necessary condition for equilibrium noted above is fulfilled. The force $\boldsymbol{F}_1$ gives rise to a clockwise torque, or moment, of magnitude $F_1\, l_1$ about the point $O$, which is balanced by the counterclockwise moment $F_2\, l_2$ of the force $\boldsymbol{F}_2$. It appears that to



*Figs. 8* (left) *and 9* (right)—*Analysis of a lever acting at an angle, and use of vector products, respectively*

prevent the rotation, the algebraic sum of the moments must vanish if the body is to be in equilibrium. If the force $\boldsymbol{F}$ acts at angle $\theta$ with the rod as shown in Fig. 8, this force can be thought of as being the sum of two component forces, one of which, $\boldsymbol{F}_p$, of magnitude $F \cos \theta$, acts parallel to the rod and is balanced by the reactive force $-\boldsymbol{F}_p$ applied to the pivot, and the other, $\boldsymbol{F}_n$, of magnitude $F \sin \theta$, is directed at right angles to the lever arm. In this case, the torque of the force $\boldsymbol{F}$ will have the magnitude $F\, l \sin \theta$, and it can be counterbalanced by any force giving rise to a counterclockwise moment of magnitude $F\, l \sin \theta$.

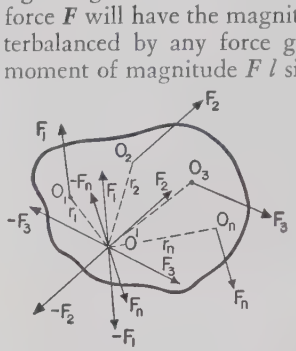


*Fig. 10*—CONDITION OF EQUILIBRIUM IN A RIGID BODY

In order to take proper account of the signs of the moments when a large number of forces act on a body, the moment of force $\boldsymbol{F}$ about any point $O$ of the body (Fig. 9) can be regarded as a vector $\boldsymbol{L}$ which is the vector product $\boldsymbol{r} \times \boldsymbol{F}$ of the position vector $r$ and the force $\boldsymbol{F}$. Thus $\boldsymbol{L} = \boldsymbol{r} \times \boldsymbol{F}$. If a rigid body is acted on by a system of forces applied at the points $O_1, O_2, \ldots, O_n$ (Fig. 10), then it is easy to show that for any point $O'$ of the body, the given system can be replaced by a single force $\boldsymbol{R}$, the resultant of $\boldsymbol{F}_1, \boldsymbol{F}_2, \ldots, \boldsymbol{F}_n$, and a couple $\boldsymbol{L}$ whose moment is equal to the sum $\boldsymbol{r}_1 \times \boldsymbol{F}_1 + \boldsymbol{r}_2 \times \boldsymbol{F}_2 + \ldots + \boldsymbol{r}_n \times \boldsymbol{F}_n$. This fact follows almost immediately if one applies at point $O'$ a system of pairs of equal and oppositely directed forces $\boldsymbol{F}_1, -\boldsymbol{F}_1; \boldsymbol{F}_2, -\boldsymbol{F}_2; \ldots \boldsymbol{F}_n, -\boldsymbol{F}_n$, which obviously do not alter the state of a rigid body.

Now the force $\boldsymbol{F}_1$ applied at $O_1$ and the force $-\boldsymbol{F}$ applied at $O'$ form a couple whose moment about $O'$ is $\boldsymbol{r}_1 \times \boldsymbol{F}_1$. Similarly, the forces $\boldsymbol{F}_2$ and $-\boldsymbol{F}_2$ acting at $O_2$ and $O'$, respectively, give rise to a couple of moment $\boldsymbol{r}_2 \times \boldsymbol{F}_2$, and so on. The resultant moment $\boldsymbol{L}$ of the couples so formed about the point $O'$ is equal to $\boldsymbol{L} = \boldsymbol{r}_1 \times \boldsymbol{F}_1 + \boldsymbol{r}_2 \times \boldsymbol{F}_2 + \ldots + \boldsymbol{r}_n \times \boldsymbol{F}_n$. The remaining forces $\boldsymbol{F}_1, \boldsymbol{F}_2, \ldots, \boldsymbol{F}_n$ acting at $O'$ add up to give the resultant $\boldsymbol{R}$. Now, unless $\boldsymbol{R}$ and $\boldsymbol{L}$ vanish, the system will not be in equilibrium. Hence, the vanishing of both $\boldsymbol{R}$ and $\boldsymbol{L}$ is a necessary condition of equilibrium. This condition can also be shown to be sufficient for equilibrium if the body is initially at rest. Thus, the problem of equilibrium reduces to two analytic conditions $\boldsymbol{R} = 0$ and $\boldsymbol{L} = 0$. These equations give the mathematical statement of the principle of equilibrium.

The theory of statics is used extensively in the analysis of forces acting on structures. In case of continuous distribution of forces, the sums giving rise to the resultant moment $\boldsymbol{L}$ and the resultant force $\boldsymbol{R}$ are replaced by the corresponding integrals $\boldsymbol{L} = \int (\boldsymbol{r} \times \boldsymbol{F})\, dm$ and $\boldsymbol{R} = \int \boldsymbol{F} dm$, in accordance with the usual procedures of the integral calculus. *See also* MECHANICS; STRUCTURE ANALYSIS. I. S. S.

**STATIONS OF THE CROSS** (Way of the Cross), (1) representations of (usually) fourteen scenes in the Passion of Christ, and (2) a special devotion performed in connection with these. The practice of this devotion, traced to about the fifteenth century and connected with pilgrimages to Jerusalem, became general in the seventeenth century, many indulgences being attached thereto by the popes. The devotion consists normally in passing from station to station while meditating on the sufferings of Christ; set prayers are sometimes recited and the *Stabat Mater* sung. N. J. T.

**STATISM,** a term, until recently an obsolete synonym for statecraft, that has come into use, notably since the 1930's, as a general expression for governmental concern with, and involvement in, the economic and business activities and welfare of the people. Although *statism* also implies growing dominance of the political power in other aspects of life, the controls, interference, and proprietary activities characterizing it have their principal impacts upon the means by which nations gain their livelihood.

Inevitably, however, involvement of government, or the state, in oversight of the nation's economy puts its stamp upon attitudes and outlook broadly affecting society as a whole. The repercussions of statism in its various forms are on an international, as well as a national, scale. Pouring economic and business activity into molds of political policy enhances the economic importance of national boundaries and complicates international diplomacy to the extent that transactions, otherwise the primary or sole concern of individuals or of business groups, become at least in part the responsibility of governments. A great growth of such responsibility has characterized the decades since the outbreak of World War I. In fact, the mid-twentieth century period finds statism so pronounced and widespread that many parallels suggest themselves with the programs of eighteenth century and earlier mercantilism, which were largely swept away by the rising tides of the Industrial Revolution.

In general, there may be distinguished three levels of political or government involvement in economic and business activities. These levels, or stages, imperceptibly merge into each other. They represent no clear-cut pattern of historical evolution; in fact, they often co-exist within the economy of a single country, and they are coterminous in Europe and elsewhere. Nevertheless, these levels of governmental intervention do serve to point up the possible pattern of progression (or of retrogression, depending upon the observer's outlook) from a minimum of political interference, often referred to as "laissez faire" ("let things alone," "keep hands off"), to the complete absorption of the people into the state, or totalitarianism in its several forms.

On the *first* of these stages of political involvement in business, the state concerns itself with establishing or shoring-up the essential national foundations of economic activity, and with helping to create and enforce the "rules of the game." Numerous and necessary as are the points of contact between agencies of government and persons engaging in economic activities, the scope of government on this first level is wholly compatible with an economically dominant private capitalism. It is the nearest feasible approach to a laissez-faire state of affairs in the relations of business and government.

The ideals of freedom and equality expressed in the Declaration of Independence and of freedom expressed in the Federal Constitutional Bill of Rights are epitomized in the phrase "life, liberty, and property," which are not to be taken "without due process." The very existence of private property, however, which was closely associated with the other freedoms by the Republic's founding fathers, is dependent upon a complicated network of laws, regulations, and court decisions underlying contractual relationships. Hence it may be said that government is necessarily an integral part of business. The great question is how far governments need to be involved in order to serve best the interests of society in general.

On the *second* level of governmental involvement in economic activity, the state assumes a supervisory role without dominating or actually taking over the functions of private enterprise. Here, two stages may be broadly distinguished; one, that of predominantly *indirect* controls; two, that of *direct* controls, generally accompanied by, and often supplementing, indirect controls.

Such controls, exerted by agencies of government in many directions and by many means, will be illustrated below. They arise in part from theoretical appraisal of the deficiencies of private enterprise capitalism and from experimentation in political intervention to which this gives birth. In part they arise from efforts, studied or sporadic, to meet existing emergencies by governmental action "from above" based upon the sovereignty of the state, which as a last resort can add the sanction of physical force to the economic and moral sanctions that undergird most social activity. The direct and indirect controls characterizing this second level of statism do, however, all imply the inability of private enterprise, when left largely to its own devices, to serve adequately the nation's needs. The direct controls take over some functions, or notably impinge upon some prerogatives, of business and labor management.

The *third* level of state participation in economic and related social activities is that of direct and proprietary business activity, or "government trading." This replaces, or at least takes the place of, private enterprise capitalism. It may spread over only part of the nation's economic activity or may completely engulf it. It may be the result of *evolutionary* or *revolutionary* process, or of both, if any clear-cut distinction can be made between them. Government trading on a large scale (state socialism) coexists in some countries with a considerable measure of personal freedom, that is, with the political liberties and basic human rights of individuals and minorities, without which democracy as understood in the West is inconceivable. When state ownership and management absorb the bulk or all of economic activities, as in countries behind the Iron Curtain, there results a totalitarianism which completely subordinates the individual to the dictatorially led and all-powerful government.

Historically associated with these three levels of governmental relationship to the economy are three schools of thought, or more accurately, three approaches to the economic analysis of human behavior. These are perhaps best exemplified in Adam Smith, as a founder of classical economics; in Karl Marx as the chief intellectual architect of socialism and the class struggle; and in John Maynard Keynes as the most influential exponent in our times of the responsibility of the state in controlling business fluctuations and in preventing underemployment. In noting these associations, however, it would be misleading wholly to identify these thinkers with the attitudes and rationalizations of government-business relationships on the different levels just described. It would equally be a mistake to ignore the often conflicting emphases and theories among the many writers who in general view the situation from one or another of these three vantage points.

Thus, Adam Smith's *Inquiry into the Nature and Causes of the Wealth of Nations,* published in 1776, took an optimistic view of the outlook for mankind, provided the state controls over commerce and handicrafts that had been for centuries typical of mercantilism were relaxed and scope given for individual initiative and division of labor in exploiting a bountiful nature. On the other hand, his immediate successors among the classical economists, like Ricardo,

stressed the niggardliness of nature; and, like Malthus, the tendency of population growth to press against means of subsistence—thus bringing down upon the new doctrines of economics the characterization of "the dismal science."

Nevertheless, a characteristic attitude of these thinkers and their followers may be summed up in a virile opposition to over-meddlesome governments, so far as the rising tide of industrial and commercial activity was concerned, and a faith in reasonably just output and distribution of wealth, provided the people were allowed scope for exercising their natural rights, and regulation of economic activities were left to the market places. The application of these ideas in the field of international commerce, as promoted by the Manchester School in England, had a great deal to do with the establishment of comparatively "free trade" between the British Empire and the rest of the world during a considerable part of the nineteenth century and until the global wars of the twentieth century undermined the freely-operating international gold standard and the multilateralism and nondiscrimination in exchange of commodities which accompanied it.

A far different philosophical approach, also rooted in the dynamism of the industrial revolution, has led in the opposite direction of fastening upon men the tentacles of governmental bureaucracy in dictatorially dominated, all-powerful totalitarian states. Karl Marx and Friedrich Engels brought out their *Communist Manifesto* in 1847, and the former's *Das Kapital* (Vol. I) appeared in 1867. With so-called "Utopian Socialists," these writers held that labor was the creator of all wealth and was continuously exploited by the toll of profits, rents, and interest exacted from production by private-enterprise capitalism.

Marx saw in this the inevitable downfall of capitalism, as its products, he argued, could not be fully absorbed by the masses who produced them. Cataclysmic business cycles would be followed by revolutionary expropriation of the hitherto privately-owned means of production and exchange. This, Marx reasoned, would end the class struggle by ushering in a classless society. Communist revolutionaries would thus act as midwives of destiny, hastening the dictatorship of the proletariat, a transitional period to be followed by a withering away of the state.

It is obvious that Communist Russia and its satellites behind the Iron Curtain show no evidences of any withering away of the functions and controls of government. The seemingly permanent, rather than merely transitional, dictatorship is, of course, to be explained in wider terms than Marx's mid-nineteenth century theories, which were developed against a background of labor exploitation, in the days before factory codes, child labor laws, recognized collective bargaining, and more equitable sharing of fast increasing production eased the lot of the workers. It must in part be explained by the new dispensation of Marxist theory originating in Lenin, Stalin, Trotsky, and other Communist doctrinaires; by political and economic conditions peculiar to Russia; and by the continuing aggressive thrusts of age-long Russian imperialism.

Wth the publication, in 1930, of *The General Theory of Employment, Interest and Money* by the late Lord Keynes, came the most reasoned and the most convincing statement of the case for governmental intervention as a means of saving private enterprise capitalism from its alleged inherent weakness of recurrent depression and underemployment. So great has been Keynes' influence upon current economic thought that "Keynesianism," which to a certain extent mirrored the business failures and unemployment of the 1930's, has gained a following among contemporary economists who, in their refinements and new applications assume for it a more than passing validity.

Since the ideas of Keynes have also taken hold in government circles and have given theoretical justification for certain aspects of present-day statism, the briefest résumé of his system of thought is in order. Keynes maintained that as income increases, the tendency to save rises at the expense of the tendency to consume. Orthodox economic reasoning had taken the view that failure of consumers to use up all their income would not bog down demand for the products of industry, because reductions in interest rates, resulting from a higher rate of savings, would make more attractive to business men the borrowing and investment of these savings in purchase of capital goods, in the employment of labor, and in otherwise facilitating production and its accompanying demand.

Keynes, however, denied the role of interest rates in equating the demand for, and supply of, consumer savings or capital. Interest was for him largely an expression of "liquidity preference," i.e., the extent to which individuals and business firms prefer cash in hand, including bank demand deposits, to less liquid assets. This liquidity preference would not permit low enough levels of interest rates to attract investment in business ventures at a time when, as Keynes saw it, the "marginal efficiency" of capital was declining. Hence thrift might actually be dangerous to economic stability, since it could weaken consumer demand without a compensating strengthening of producer demand.

Granted these hypotheses of Keynesian logic, the result, short of state intervention, would appear to be a slowing up of production, a consequent unemployment or underemployment of labor, and a fall in income to levels at which the resulting rising tendency to consume would take off the market the smaller volume of products, and the diminishing tendency to save would bring savings into line with the effective demand for capital. These disturbing shorter-term maladjustments between savings and investment tend toward the establishment of equilibrium, under private enterprise capitalism, at rates of production and marketing permitting less in the way of employment and income than the economy could and should provide.

Perhaps it would not be too facetious to say that here is where the tenets of Keynesianism call in the state to help set right these assumed inherent deficiencies of private enterprise capitalism, in somewhat the same manner as ancient Greek dramatists introduced gods by special stage machinery to straighten out the affairs of men at critical junctures. Alarmed by notions of a slowing-up, or a "mature" economy, and impressed by the Western European and American trends, noticeable during the 1930's, toward an aging and stationary population, numbers of economists, business men and politicians have subscribed to a program of governmental injections of credit and purchasing power into the body economic as a normal and dependable means of shoring up and stabilizing the economy.

These expressions of statism, which spring from reliance upon government to mitigate business fluctuations and to promote full employment, generally take the form of indirect controls. Thus, unbalanced budgets, by sponging up, through taxes, less in purchasing power than is released by government spending are relied upon as a shot in the arm for faltering employment. By the same token a surplus in the national budget is advocated to poultice a boom, though this kind of treatment runs up against the natural

political impulse to spend freely and tax lightly in good as well as bad times. The central banks, mostly governmentally controlled, ease and tighten credit with the same objectives in mind. The state sets up its own lending and financing agencies more immediately to affect the tempo of economic activity. Substantial programs of public works are carried out or held in reserve, as the case may be.

Such forms of economic statism necessarily rely upon tight governmental control of the nation's money and of its central banks. This is, of course, also true of socialistic and totalitarian regimes. Inconvertible currencies may be expanded or contracted as tools of control at the will of the political regime, whose obligations may be bought by the banks to bolster their market values and to keep interest rates at artificially low levels. This is really a means of converting government debt into current purchasing power. It frees the regime from complete dependence upon taxes and from controls over fiscal and monetary policies of the kind exerted by the people of gold-standard countries prior to the 1930's, when their confidence in the currency could be put, at any time, to the acid test of demand for redemption in the precious metal. In this connection can be noted the significance of the 1951 agreement between the Treasury Department and the Federal Reserve Board, freeing the latter of any obligation to keep U.S. government bonds at parity or above and subordinating the Treasury's desire for minimum interest rates to the general credit needs of a private enterprise economy.

The international repercussions of statism stem principally from substitution of governmental action or responsibility in place of the transactions of innumerable individuals and going concerns freely operating, both domestically and in foreign countries, in industry, commerce, investment and travel. Free operation characterized the vast expansion of production and trade in the nineteenth and early twentieth centuries; government control has typified the era of the two world wars.

In fact, restrictions currently imposed by governments, from a variety of needs and purposes, upon foreign exchange, imports, and exports (tariffs, quotas, preferences, and bounties), sources and destinations of commodities, international allocations of raw materials, shipping, investments, movement of persons, prices, collections, subsidies, buying in the lowest markets, selling in the highest markets, and so on, have many points of resemblance to the mercantilism of earlier centuries. They may, therefore, be considered a return to methods of the past.

The nationalism which accompanies and partly accounts for these various manifestations of statism is in turn aggravated by it. Thus, a continuing government oversight of the economy leads to partial insulation from possibly disturbing influences originating in other countries. The indirect controls in the political storehouse of economic weapons are often supplemented or replaced by such direct controls as wage and price stabilization through ceilings, floors, parity prices, and other devices mentioned above. State socialism, with its responsibilities of industrial ownership and management, tends to be more nationalistic than the private enterprise capitalism, which it has traditionally denounced for imperialism. The totalitarian regimes of Soviet Russia and her satellites will, of course, brook no interference from abroad.

Thus, statism shows certain tendencies toward self-perpetuation. The longer a country's monetary and credit system has been politically manipulated to centrally dominate the economy, the more difficult is its recovery of a flexible response to the commercial and industrial needs of the nation's business. Nationalism, it may be repeated, increases the economic significance of political frontiers. Nationalism enhances the struggle for self-sufficiency, which in turn spreads the threat of war, feeds the fires of nationalism, and, thereby, completes the vicious circle. Controls, both direct and indirect, call for continuous extension in the interests of justice and effectiveness. Instability seems to haunt hybrid or half-way systems between direction of the economy by market prices, and direction from above by government.

The principal origins of statism in our time now seem clear. They may be briefly summarized as follows: 1. The impacts of war, of the aftermath of war, and of the imperatives of defense mobilization; 2. The efforts to implement certain theories, or ideologies—from state socialism in a democratic context, to monopolistic government trading within a totalitarian framework; 3. The application of governmental remedies to the economic problems of unemployment and disturbing business fluctuations; 4. Processes of drift and evolution which are not immediately associated with any of the foregoing.

The purposes served, or sought to be served, in varying degree by the many forms of governmental control, intervention, and ownership known as statism range from acting umpire, setting the rules of the game, and conserving and developing the nation's resources in attempts to strengthen competitive private enterprise, on the one hand, to guarding the international balance of payments, demonstrating the superiority of government enterprise, and, in totalitarian systems, converting the nation into an armed camp fired by fears and hatreds directed toward foreigners and minorities on the other.

In this connection it should be borne in mind that overlordship by the state which justifies the term "totalitarianism" may come about without replacement of private enterprise capitalism by direct and proprietary governmental business activity. Nazism, or the rule of "the National Socialist German Labor Party," from the early 1930's until the end of the Second World War; and Fascism in Italy from the early 1920's until the downfall of Mussolini are the best examples of this. However, although "Communism," or "Sovietism," is assumed to be of "the Left," and "Nazism" and "Fascism," of "the Right," there is here, in some respects, a case of extremes meeting—if in fact they are extremes at all.

Thus in all these authoritarian systems the citizen is exhorted and expected to identify himself with the national group, which is also identified with the existing regime, or government. An integral part of the regime is the unitary "party"—Communist, Fascist, or Nazi, as the case may be. The domineering party is in turn dominated by a dictator, clique, or junta, who maintains himself, or which maintains itself, in power by rigorous control of electoral candidacy lists confined to followers of the "party line." Despite the preservation of the institutions of private property in totalitarian systems of the "Right," such as Nazism and Fascism, the initiative, responsibility and authority of the individual citizen and of the business entrepreneur are definitely circumscribed by and subject to the overriding will of the dictatorship.

In Germany, for instance, Hitler and his Nazi high command became economic as well as political dictators. It has been pointed out by competent observers close to the scene that, as a means of socializing the whole apparatus of production and distribution, including agriculture as

well as industry, the pervasive governmental controls under Nazism proved more effective than expropriation. The program of general governmental centralization and domination, embodied in the aggressive military build-up and in other deficit-financed attacks upon mass unemployment went far beyond the party program announced in 1920, Point 13 of which ("Nationalization of all big incorporated business 'trusts' . . .") was transcended in every field of economic and social activity, *de facto,* if not *de jure.* The substance of the institution of private property was destroyed; only the shadow remained.

The challenge, thrown by Nazi militants at German Socialist parties during the time of the Weimar Republic revealed, in such slogans as abolition of unearned incomes, and "breaking the bondage of interest slavery," that imitation which is the sincerest flattery. In some respects Nazism may be considered a sinister lineal descendant of the state socialism which, originating and always finding a spiritual home in Germany, never repudiated the institutions of family and private property, and went far in encouraging the protective legislation and the benevolent paternalism espoused by Bismarck and his successors.

In its deviations from, rather than in its espousal of, traditional socialist doctrines, Nazism showed a fundamental kinship with Fascism, whose origins, also in part socialistic, were ideologically related to French (revolutionary) Syndicalism and to British Guild Socialism. The collectivist doctrines of Hitler, Mussolini, and their polemicists found support in the early twentieth century wedding of nationalism and socialism in the writings of Friedrich Naumann, who envisaged incorporation of the workers into the state as a means of countering the Marxian class struggle; and in the gloomy philosophy of Oswald Spengler, whose dim view of democracy and liberalism suggested the alternative of a contemporary Caesar.

As against the mysticism, romanticism, and anti-intellectualism of the Nazi movement, however, with its anti-semitism and racialism (ideas partially attributable to Adam Müller and Houston Stewart Chamberlain respectively), Fascism tended toward realism and empiricism in its years of initial power. It later jelled into an elaborate system of federation, confederation and guild (or "corporazion") organization of workers and employers, in contrast with the opportunistic, heavy-handed, and rather inchoate strategy of the Nazi dictatorship.

Fascism borrowed from Syndicalist beliefs in functional economic organization, in the impotence of parliamentary democracy, in the responsibility of occupational groups for the reorganization of government and society, and in the mission of the élite in guiding the entire process. Drawing upon its sturdy Italian nationalism, however, Fascism sought to strengthen rather than destroy the state, and to fasten its centralized controls upon all productive groups. In these latter respects, at least, it departed far from the ideology of Georges Sorel who, among the most prominent of French Syndicalist writers, repudiated political parties and the bourgeois state and handed the revolutionary role wholly to the working proletariat.

In emphasizing the dominance of central government the Fascist regime also parted company with the doctrines of Guild Socialism, a milder and more evolutionary philosophy than Syndicalism. This movement, in which G. D. H. Cole, R. H. Tawney, and a number of other prominent English writers set the pace during the first two decades of our century, called for largely self-governing productive groups which, through cooperation, would create a "functional democracy" with workers controlling industry. The Fascist conception, on the contrary, was the Guild, or Corporative organization of the state as a means of asserting governmental supremacy in all directions—suppressing local autonomy and subjecting men and property to the overriding requirements of national policy as determined from above.

Reverting, then, to the earlier comparisons drawn among these totalitarian regimes, whether based upon nationalization or not, it is fundamental to understand the relative impotence of the voters, the arbitrary state controls, the leadership principle, the lack of representative and free labor unionism, and the insecurity of individuals and minorities which characterize them all.

Descriptions of statism as it exists in different parts of the world today would far transcend the limits of any article. It is possible, however, to distinguish in general terms among countries like the United States, Canada, and certain Western European nations, where private enterprise capitalism dominates the economic scene; countries like Great Britain and the Scandinavian group which follow the "middle way" of mixing state socialism with co-operative undertakings and privately capitalized enterprise; countries like Russia and her satellites which subordinate the individual to the monopolizing and all powerful government; and countries like India and Pakistan whose undeveloped economies and paucity of capital, skilled labor, and know-how seem to call for government guidance and international aid in raising the people's living standards. These latter countries obviously fall into none of the earlier classifications.

In gauging the force of statism in any country it is necessary to appraise the role played by government against the background of national resources and historical economic evolution. The American traditions of free enterprise were greatly fortified by a seemingly limitless frontier, a rapidly growing but never excessive population, and a heritage of political freedom and egalitarian philosophy. Even in the United States, however, ambitious government planning on the national as well as the state level had much to do with shaping the national economy, from Alexander Hamilton's protective tariff to the state and Federal boosts given railways, highways, canals, banks, prospectors, homesteaders, and others.

In most European countries, as elsewhere, governments have historically helped to finance and have often directly participated in economic activities here traditionally reserved for private enterprise. It is to be expected that this pattern will be repeated and intensified in countries now economically struggling to their feet. At the same time, governments currently plagued with balance of payments difficulties, with depressed standards of living, with the dangers of war, or with the challenge of undeveloped resources are in some notable instances increasingly cooperating among themselves, and with private enterprise, in laying the foundations of a better order. International technical aid, the General Agreement on Tariffs and Trade, the western European Coal and Steel Community, the Colombo Plan, and the European Payments Union are steps in this direction.

This realistic rather than doctrinal approach in meeting the world's ills may go far toward providing common meeting ground for advocates of "laissez faire" and the devotees of statism. In any case, it helps focus attention upon the problems of the peoples, which too often are obscured by the maneuvers of the powers. L. R. R.

**STATISTICAL MECHANICS.** *See* KINETIC THEORY AND STATISTICAL MECHANICS.

**STATISTICS,** the science of classification and manipulation of data in order to draw inferences.

The basic materials with which a statistician operates are numbers. Sometimes these numbers arise from counting, and sometimes they arise from measurement. Vital statistics such as the number of births and deaths or the number of marriages in a state in a given period of time arise from counting. Such numbers are usually called discrete data. In some situations, measurement comes from a scale; examples are length, weight, and time. Such data are usually called continuous, even though the measurements themselves can only be taken to a certain degree of fineness.

**Census.** There are two principal ways to gather data: by census or by sample. In either case, it is necessary to define the population or aggregate of objects under consideration. If one is interested in heights of people, for example, the population might be 20-year-old white males from California. Using the census technique, one would measure the height of every person in the defined population. Such a procedure would be costly and difficult to administer. Furthermore, a census of a large population is seldom complete. A more practical way to study the distribution of heights would be to take a carefully selected sample of say 2,500 males of the type specified.

**Sampling.** There are several kinds of sampling. One of the most frequently employed methods is random sampling. In random sampling, each element of the population has an equal chance of appearing in the sample, and the probability that an element appears in the sample is unaffected by the appearance of another element. Often stratified sampling is used either to get more accuracy than that supplied by random sampling, or to improve comparisons of groups within the population. In stratified sampling, the population is divided into levels or strata, usually on the basis of some variable other than that being measured. In the example on heights of men, one might take as a strata persons in cities of a population less than or equal to 25,000 and persons in cities of a population greater than 25,000. In general, if the population is of size $N$, and the $k$ strata of sizes are $N_1, N_2, \ldots, N_k$, where $N = N_1 + N_2 + \ldots + N_k = \Sigma Ni$, a stratified sample of $n$ is formed by taking a random sample of size $n_1$ from the stratum of $N_1$, a random sample of size $n_2$ from the stratum of $N_2$, and so forth such that $n = \Sigma n_i$. In stratified sampling, the $n_i$ are not necessarily proportional to the $N_i$, but an important special case of stratified sampling is proportional or representative sampling in which $n_i = N_i n/N$, $i = 1, 2, \ldots, k$. In systematic sampling, the elements of the population are arranged in an arbitrary order and numbered $1, 2, \ldots, N$. The desired sample size $n$ is selected and an integral interval $k = N/n$ is chosen. A random choice is made of the numbers $1, 2, \ldots, k$. Suppose it to be $l$. Then the sequence of elements numbered $l,\ l+k,\ l+2k, \ldots, l+rk$, $N-k < l+rk \leq N$, forms the systematic sample.

## DISTRIBUTIONS

It is often convenient to think of populations and samples as forming distributions. When dealing with discrete data, a frequency distribution gives the number of occurrences at each value of the variate being measured. In the case of measurement data, the variate is broken up into convenient-sized intervals, usually of equal length, and the frequency distribution gives the number of cases included in each interval. Such data are usually presented in the form of a graph such as a histogram, or tabularized as in the following example:

RECORD OF SOLDIERS DYING FROM KICKS OF HORSES

| *Number of Deaths in a Corps per Year* | *Frequency* |
|---|---|
| 0 | 109 |
| 1 | 65 |
| 2 | 22 |
| 3 | 3 |
| 4 | 1 |
| 5 | 0 |
| Total | 200 |

The first column of the table represents the number of deaths resulting from kicks by horses in one army corps in one year. The number of times exactly 2 deaths occurred is 22. This same information can also be shown graphically.

In mathematical statistics it is often necessary to deal with hypothetical distribution functions. If we have an integrable function $y = f(x)$ defined on the real axis, such that $\int_{-\infty}^{\infty} f(t)dt = 1$, $f(x) \geq 0$, $-\infty \leq x \leq \infty$, we may use it as a probability model. The probability of a value of $x$ in the interval $[u, v]$ is defined as:

$$P(u \leq x \leq v) = \int_u^v f(t)dt.$$

Under these conditions $f(x)$ is called a probability density function. The total area under the curve is unity, while the area over the interval $[u, v]$ is thought of as the long-run proportion of the times randomly chosen values of $x$ will fall in the interval under repeated sampling.

In the case of discrete data for which the variate takes on the values $x_1, x_2, \ldots$, the density function $y = p(x_i)$ is such that $\sum_i p(x_i) = 1$, $p(x_i) \geq 0$ for all $x_i$, and the probability of a particular set of $x_i$'s is merely the sum of the $p(x_i)$ over the appropriate set.

**Gaussian Distribution.** An important continuous distribution function is the general, normal, or Gaussian, distribution $y = (1/\sqrt{2\pi}\sigma)e^{-(x-a)^2/2\sigma^2}$. It is often used to approximate distributions of measurements in industry, psychology, education, and anthropology. Although it cannot be hoped that any kind of practical measurement will behave exactly like the mathematical model described by the normal distribution, it has been found to be extremely useful as an approximation to many physical phenomena.

**Binomial Distribution.** An example of a discrete distribution is the binomial distribution. If $p$ is the probability that a success occurs on a single trial, and $n$ is the number of trials, then the probability that exactly $x$ successes occur is:

$$P(x) = \frac{n!}{x!(n-x)!}\, p^x(1-p)^{n-x}, x = 0, 1, \ldots, n,$$

where $n! = n(n-1)(n-2) \ldots 3 \cdot 2 \cdot 1$, $0! = 1$. The binomial distribution is useful in dealing with genetic problems, public opinion polling, games of chance, or inspection of manufactured products. *Example:* If a fair die is thrown five times, what is the probability of no more than one ace appearing? Here, the probability of an ace appearing on a single throw is $p = 1/6$. The probability of no more than one ace is $P(0) + P(1) = (5!/0!5!)(1/6)^0(5/6)^5 + (5!/1!4!) \cdot (1/6)(5/6)^4 = 0.804$. This means that, in the long run, about 80 per cent of tosses of five dice will result in no more than one ace.

**Poisson Distribution.** Another useful discrete distribution is the Poisson distribution. If the average number of

occurrences of a phenomenon is $m$ per trial, the probability that exactly $x$ appear is given by:

$$P(x) = \frac{e^{-m} m^x}{x!} \quad x = 0, 1, 2, \ldots,$$

when the distribution is Poisson. The Poisson distribution is useful in dealing with events which happen in fixed intervals of time or fixed areas, such as the number of counts on a Geiger counter in a 15-second interval, the number of wireworms appearing in plots of ground six inches on a side, the number of phone calls in a given period, the number of bacteria in a certain area of a culture, and the number of accidents in a certain period of time.

## LOCATION PARAMETERS AND MEASURES OF VARIABILITY

**Arithmetic Mean.** In describing populations or samples, it is helpful to be able to present one or two numbers which provide the reader with a summary of the data at hand. Such numbers are often called descriptive statistics. The arithmetic mean or average is probably the best-known descriptive statistic. If we have a set of $n$ observed values $x_1, x_2, \ldots, x_n$, the arithmetic mean is defined as:

$$\bar{x} = (x_1 + x_2 + \ldots + x_n)/n = \Sigma x_i/n.$$

If the $n$ observations form the whole population, $\bar{x}$ is the population mean; while if they are a random sample from some population observations, $\bar{x}$ is the sample mean. In the latter case the sample mean is said to be an estimate of the true population mean. Usually the true population mean is unknown, and the sample mean is used to estimate it.

**Median.** Another useful descriptive statistic is the median. If the sample size is odd, the median is the middlemost observation, thus of 2.14, 3.29, 4.32, 4.40, 4.64, the number 4.32 is the median. If the sample size is even, the median is usually defined to be halfway between the two most centrally placed observations. If we add 4.93 to our previous set of five observations the median of the six observations is $(4.32 + 4.40)/2 = 4.36$. The median of a sample is an estimate of that position on a distribution such that 50 per cent of the distribution lies below it and 50 per cent lies above.

The mean and the median are called location parameters of a distribution function, because the shape of a distribution can remain unchanged even though its mean or median changes. Thus, if a distribution function is rigidly translated $x$ units to the right, $x$ units are added to the mean and median. For symmetrical distributions the mean and median are identical.

**Variability.** In addition to location parameters, it is useful to give some idea of the variability of the distribution. Perhaps the simplest measure of spread or variability is the range:

$$\mathrm{R} = \text{largest value} - \text{smallest value}.$$

In the tabular example which has been given, the number of deaths per corps per year ranges from 0 to 3, and so the range is 3. The range is particularly useful in connection with small samples, and it is widely used in industrial work.

**Standard Deviation.** For many purposes the standard deviation is a useful measure of spread. If we have observations $x_1, x_2, \ldots, x_n$, the standard deviation $s'$ is defined as the root-mean-squared deviation from the mean:

$$s' = \sqrt{\Sigma(x_i - \bar{x})^2/n}.$$

For many kinds of data met in practice, this statistic has the useful property that in large samples about two-thirds of the observations lie between $\bar{x} + s'$ and $\bar{x} - s'$, and about 95 per cent of the observations lie between $\bar{x} + 2s'$ and $\bar{x} - 2s'$. The more nearly normally distributed the data, the better these approximations hold.

If we have a theoretical probability distribution function $f(x)$, it can often be conveniently described by its moments. The $k$th raw moment of $f(x)$, if it exists, is defined by:

$$\nu_k = \int_{-\infty}^{\infty} x^k f(x)\,dx;$$

note that $\nu_0 = 1$, and $\nu_1 = a$ is called the population mean. The $k$th moment about the mean $a$, if it exists, is defined as:

$$\mu_k = \int_{-\infty}^{\infty} (x-a)^k f(x)\,dx.$$

We note that $\mu_0 = 1$, $\mu_1 = 0$, and $\mu_2 = \sigma^2$ is called the variance of the distribution, while $\sqrt{\mu_2} = \sigma$ is called the standard deviation of the distribution.

*Tchebycheff's Inequality* states that no matter what the distribution is, the total probability contained within the limits $a + \lambda\sigma$, $a - \lambda\sigma$ is:

$$P(a + \lambda\sigma \geq x \geq a - \lambda\sigma) \leq 1 - 1/\lambda^2.$$

It will be noted that this inequality says far less than the remark made earlier about the proportions lying within one or two standard deviations of the mean. However, this is a mathematically rigorous statement, and holds for pathological distributions, while the earlier statement is a rough guide for practical work in the presence of nicely distributed data.

In passing it should be noted that when the normal distribution is written

$$y = \frac{1}{\sqrt{2\pi}\sigma} e^{-(x-a)^2/2\sigma^2},$$

the mean or first moment is $a$, while the variance $\mu_2 = \sigma^2$. Consequently, for the normal distribution it suffices to specify the mean and variance to determine the distribution function completely.

Similarly, the binomial distribution $P(x) = (n!/x!(n-x)!)\, p^x (1-p)^{n-x}$ is completely specified by $p$ and $n$. The mean number of successes $a = np$, while the variance of the number of successes is $\sigma^2 = np(1-p)$.

The Poisson distribution $P(x) = e^{-m} m^x/x!$ is specified by one parameter $m$. The mean value of $x$ is $m$, and the variance of $x$ is also $m$.

In general, if there is a distribution function $f(x)$ *and* another function $g(x)$, there is said to be the expected value of $g(x)$ written:

$$E\Big[g(x)\Big] = \int_{-\infty}^{\infty} g(x) f(x)\,dx.$$

Consequently, the moments of a distribution function are often called the expected values of $x^k$, $E(x^k)$.

## POINT ESTIMATION

An important statistical problem is the estimation of parameters of distribution functions. The expression, point estimation, implies that a single number is offered as an estimate of a parameter rather than a range of values. When a range of values is offered as an estimate, one speaks of interval estimation.

In general, the sample mean $\bar{x}$ is an estimate of the population mean $a$. If one thinks of repeatedly drawing a sample of size $n$ from a distribution $f(x)$, then one may consider the resulting $\bar{x}$'s as having a distribution of their own, say $g(\bar{x})$. If $f(x)$ has mean $a$ and finite variance $\sigma^2$, then

$g(\bar{x})$ has mean $a$ and variance $\sigma^2/n$. In the special case where $f(x)$ is normal, it happens that $g(\bar{x})$ is also normal with the parameters just given. This property of the normal distribution is called the reproductive law.

The relation between the moments of $f(x)$ and $g(x)$ makes possible an important theorem which says that when the sample size $n$ increases without limit, the probability that $x$ will deviate from $a$ by more than a fixed absolute value $\epsilon$ tends to zero. When any statistic $\theta_n$ depending on the sample tends to a value $A$ in the manner just described of $\bar{x}$, one says that $\theta_n$ converges stochastically to $A$. Symbolically, $\theta_n$ converges stochastically to $A$ when:

$$\text{Probability } (|\theta_n - A| > \epsilon) \to 0 \text{ as } n \to \infty, \text{ for every fixed } \epsilon > 0.$$

The central limit theorem also follows from the conditions relating $f(x)$ and $g(\bar{x})$. This theorem states that for an arbitrary population with mean $a$ and finite variance $\sigma^2$, as $n$ increases without limit, the distribution of $z = (\bar{x} - a)\sqrt{n}/\sigma$ tends to a limit such that:

$$P(z \leq z_0) = (1/\sqrt{2\pi}) \int_{-\infty}^{z_0} e^{-t^2/2} dt.$$

This is the precise way to say that $\bar{x}$ is asymptotically normally distributed with mean $a$ and variance $\sigma^2/n$.

The central limit theorem plus practical investigations of the behavior of distributions of sample means drawn from rather unusual distributions give the statistician considerable confidence that means of samples as small as $n = 10$ are sufficiently nearly normally distributed for most purposes. This is one of the principal reasons for the importance of the normal distribution in statistics. A second reason for the importance of the normal distribution is that it is often possible to transform non-normally distributed data to approximate normality by such devices as taking the logarithms of the original observations. Third, many theoretical distributions approach normality when certain parameters become large or small; for example, when $m > 20$, the Poisson distribution is approximately normal with mean $m$ and variance $m$.

If from a distribution $f(x)$ a sample $x_1, x_2, \ldots, x_n$ is drawn and the statistic $\theta_n$ is constructed to estimate the parameter $A$, and it turns out that the expected value $E(\theta_n) = A$, one calls $\theta_n$ an unbiased estimate of $A$. It will be noted that $\bar{x}$ is an unbiased estimate of the mean $a$.

An unbiased estimate of the variance $\sigma^2$ of a distribution when the true mean is unknown is:

$$s^2 = \Sigma(x_i - \bar{x})^2/(n-1) = ns'^2/(n-1).$$

If among all possible asymptotically normally distributed statistics $\theta, \theta', \theta'', \ldots$ whose large sample expectations are $A$, there is one which has smallest variance, it is said to be the efficient statistic for estimating $A$. If $\theta$ is an efficient statistic and $\theta'$ some other statistic in the set defined, then the efficiency of $\theta'$ relative to $\theta$ is:

$$\text{efficiency} = \sigma_\theta^2/\sigma_{\theta'}^2.$$

For example, the sample mean $x$ from a normal distribution with variance unity is an efficient statistic for estimating $a$, the true mean; it has variance $1/n$. But the sample median is also an unbiased estimate of the mean $a$; it has asymptotic variance $\pi/2n$. The efficiency of the median is $2/\pi = .64$, which means in practice that for large samples only about 64 per cent as many observations are required to obtain the same precision from the mean as from the median. However, the median is much quicker to compute, consequently it will often be economically valuable to use a less efficient statistic, sacrificing precision for time. These considerations are particularly valid when observations are cheap and analysis of data costly.

## REGRESSION

When two variables are closely related, it is often possible to use one to estimate the other. An example of this kind of relation is given by the heights and the weights of people. From a person's height his weight may be estimated, not exactly, but more precisely than if the height were not known at all.

Very frequently it is possible to use a linear estimating function to estimate a variable $y$ from another variable $x$. In some cases when linear functions are inadequate, suitable curves can be found to assist in the estimation process. For many purposes, a curve or a line sketched through the plotted observed points $(x_1, y_1), (x_2, y_2), \ldots, (x_n, y_n)$ is adequate.

If a straight line of best fit is required, the least-squares criterion may be employed. The problem then is to find the line:

$$y = a + bx,$$

such that the sum of the squares of the vertical deviations, $\Sigma(y_i - a - bx_i)^2$, of the $y$ values from the line is a minimum. This criterion will be satisfied when the normal equations:

$$\Sigma y_i = na + b\Sigma x_i,$$
$$\Sigma x_i y_i = a\Sigma x_i + b\Sigma x_i^2,$$

are solved simultaneously for $a$ and $b$.

The least-squares criterion is purely arbitrary. Its use stems from the fact that most other criteria are mathematically difficult to work with, while the least-squares criterion in the case of linear estimation requires only the solution of linear equations to obtain the regression coefficients $a$ and $b$.

In general it may be required to estimate $y$ from several variables using a linear function on the form:

$$y = a_0 + \Sigma a_i x_i.$$

The solution for the $a$'s is similar to that for the two-variable case just described.

## CORRELATION

When two variables are statistically related, it is often useful to have a measure of their relationship. One measure of this relation is the product-moment correlation coefficient defined by:

$$r = \frac{\Sigma(x_i - \bar{x})(y_i - \bar{y})}{\sqrt{\Sigma(x_i - \bar{x})^2 \, \Sigma(y_i - \bar{y})^2}}.$$

The index $r$ runs from $-1$ to $+1$. When $r$ is $\pm 1$, the variables $x$ and $y$ are functionally related by a straight line. However $r = 0$ does not necessarily imply that there is no relation between the variables, because lack of linearity can cause this phenomenon.

If $x$ and $y$ are jointly bivariately normally distributed according to the density function:

$$f(x, y)\,dx\,dy = \frac{1}{2\pi\sigma_x\sigma_y\sqrt{1-\rho^2}} \times$$
$$e^{-\frac{1}{2(1-\rho^2)}\left[\left(\frac{x-a}{\sigma_x}\right)^2 + \left(\frac{y-b}{\sigma_y}\right)^2 - 2\rho\left(\frac{x-a}{\sigma_x}\right)\left(\frac{y-b}{\sigma_y}\right)\right]} dx\,dy,$$

then $r$ is an estimate of $\rho$, the population correlation coefficient. In this case if $\rho = 0$, knowledge of one of the variables will not assist in estimating the other.

It is an error to attempt to argue causation from the existence of high correlation coefficients. High correlation merely implies concomitant variation.

One of the principal uses of the correlation coefficient is in psychological and educational work with tests and measurements of human ability and behavior.

Sometimes it is useful to use the rank correlation coefficient $R$ to measure the association between two variables. This is particularly true when the data are known not to be normally distributed. The formula for the rank correlation coefficient is:

$$R = 1 - \frac{6\Sigma d^2}{n(n^2 - 1)},$$

where $n$ is the number of observations (pairs), and $d$ is the difference in rank of a pair of observations. Example: the ranked data on eight observations of $x$ and $y$ are (1,7), (2,6), (3,8), (4,5), (5,3), (6,4), (7,1), (8,2), where the largest value of $x$ is given rank 1, the next largest rank 2, . . ., and the smallest value rank 8, and similarly for $y$. Then $\Sigma d^2 = 158$, $n = 8$, $R = -0.78$. The minus sign implies that high ranks on $x$ are associated with low ranks on $y$, and vice versa.

## TESTS OF HYPOTHESES

Tests of hypotheses or significance tests as they are sometimes called, provide experimenters with techniques for deciding whether certain statements about populations are true or false. In the statement of a test, there are two hypotheses, the null hypothesis $H_0$, and the alternative hypothesis $H_1$. Observed data will generally not agree perfectly with the null hypothesis. The experimenter computes the probability of obtaining a discrepancy greater than or equal to the one observed under the assumption that the null hypothesis is true. If the probability of greater discrepancies is high, the tendency is to accept the null hypothesis and to reject the alternative hypothesis. If the chance of observing discrepancies as large as the one obtained is small, say 0.01 or less, the experimenter has this choice: (1) he may decide that the present data represent a rare event but that the null hypothesis is true, and that the discrepancy is merely due to sampling fluctuations, or (2) he may prefer to believe that the discrepancy observed is not due to chance, that such a rare event is too unlikely, and that he would rather believe that the null hypothesis is false and that the alternative hypothesis is true.

To make a test of significance more objective the experimenter usually decides on a significance level $\alpha$ in advance. He chooses $\alpha$ so that if discrepancies larger than that observed have probability less than $\alpha$, he will reject the null hypothesis; while if the discrepancy has probability greater than $\alpha$, he accepts the null hypothesis. The choice of the significance level $\alpha$ is arbitrary with the experimenter, but it is a fairly standard practice to choose one of the values 0.05, 0.01, or 0.001.

It is important to note that neither the null hypothesis nor its alternative can either be proved or disproved; they are merely accepted or rejected on the basis of the evidence supplied by computed probabilities.

As an example, suppose that a sample of size $n = 9$ is drawn from a normal distribution with variance $\sigma^2 = 36$. The null hypothesis $H_0$ is that the true mean $a \neq 100$, and the alternative hypothesis $H_1$ is that the true mean $a = 100$. The observed mean $\bar{x} = 105$. Let the significance level $\alpha = 0.05$. The mean $\bar{x}$ of a sample of $n$ drawn from a normal distribution with mean $a$ and variance $\sigma^2$ is again normally distributed with mean $a$ and variance $\sigma_{\bar{x}}^2 = \sigma^2/n$. Therefore, assuming $H_0$ to be true, the observed discrepancy is:

$$t = \frac{|\bar{x} - a|}{\sigma_{\bar{x}}} = \frac{105 - 100}{\sqrt{\frac{36}{9}}} = 5/2 = 2.5.$$

This means that $\bar{x}$ is 2.5 standard deviations away from the mean assumed true under the null hypothesis. Tables of the normal distribution indicate that the probability of deviations of more than 1.96 standard deviations in either direction from the mean is:

$$P\left(\frac{|\bar{x} - a|}{\sigma_{\bar{x}}} \geq 1.96\right) = 1 - \frac{1}{\sqrt{2\pi}} \int_{1.96}^{1.96} e^{-x^2/2}\, dx = 0.05.$$

Since the observed deviation of 2.5 exceeds the 1.96 criterion, the null hypothesis that the population from which this sample was drawn had mean 100 is rejected. In fact, the probability of a discrepancy exceeding the one observed is $P(t \geq 2.5) = 0.012$.

The variance of the population is likely to be unknown. In large samples ($n \geq 30$) the test function $t$ is therefore replaced by:

$$t = |\bar{x} - a| \sqrt{n}/s,$$

where $s^2$ is the estimate of $\sigma^2$ defined earlier. The rest of the procedure is identical.

For small samples ($n < 30$), to test this hypothesis it is necessary to consult a table of the $t$-distribution, which appears in most texts, with $n - 1$ degrees of freedom to find out the significance of the observed discrepancy. This is necessary because $\sigma$ is unknown and must be estimated from the sample.

A common problem is that of testing whether two samples could have come from populations with the same mean. If the observed means are $\bar{x}_1$ and $\bar{x}_2$, sample sizes $n_1$ and $n_2$, and sample standard deviations $s_1$ and $s_2$, this hypothesis can be tested for large samples by using the test function:

$$t = |\bar{x}_1 - \bar{x}_2| \Big/ \sqrt{\frac{s_1^2}{n_1} + \frac{s_2^2}{n_2}},$$

and consulting a table of the normal distribution as before. Example: suppose $x_1 = 32.4$, $x_2 = 31.8$, $n_1 = 40$, $n_2 = 60$, $s_1^2 = 144$, $s_2^2 = 324$, then,

$$t = |32.4 - 31.8| / \sqrt{144/40 + 324/60} =$$
$$0.6/\sqrt{3.6 + 5.4} = 0.6/3 = 0.2.$$

The probability $P(t > 0.2) = 0.84$; consequently the null hypothesis of equal means would be accepted.

In applying tests of significance one must be careful not to confuse the concept of statistical significance with that of practical importance. A difference which could not have arisen by chance may still be so small as to be unimportant in practice, while a difference which is not significant may be of considerable practical importance if it really exists.

Many other tests of significance are available for testing hypotheses of various kinds.

## SPECIAL TOPICS

The special topics in statistics are extremely numerous. A few of the most important follow.

**Methods of Computation.** Most texts describe methods of computation which save time in the calculation of formulas of the sort presented here. Much time can be saved by grouping data and by rewriting formulas in forms suited

to the type of computation used (e.g. hand, slide rule, calculating machine, punched card, or electronic computor). Similarly, effective statistical work depends on presenting data or the implications of data effectively. Some of the best techniques are brief tables, bar charts, and color charts. A table or chart should not be too complicated.

**Design of Experiments.** The design of experiments is extremely important. Effective design requires an extensive knowledge of the topic under consideration as well as fundamental statistical knowledge. It is becoming increasingly common for authorities in various fields and for professional statisticians to co-operate in designing experiments.

**Analysis of Variance.** The signal success of the use of analysis of variance and analysis of covariance in agricultural experiments to discover the sources of variation in the yield of crops, suggested its use in other fields. This technique is becoming extremely important in investigations in education, psychology, biology, and industry.

**Non-parametric Tests.** Lack of normality of data has led to the development of nonparametric tests and nonparametric estimation. Such tests and estimates do not depend on the form of the original distribution functions. Tolerance limits developed by S. S. Wilks make it possible, in the absence of knowledge of the form of the distribution function, to assign limits on the basis of a sample. Limits assigned by this technique make possible statements of the type: at least 99 per cent of the density of a distribution is included between the limits 95 per cent of the time.

**Confidence Limits.** The technique of assigning confidence limits on the basis of a sample makes possible such a statement as: the true population parameter $A$ lies between $a$ and $b$. A certain preassigned percentage of such statements are true, say 95 per cent. It is not possible, of course, to know which statements are true and which false.

**Discriminant Function.** The discriminant function developed by R. A. Fisher is a device for classifying individuals into one of two populations, say races or species, on the basis of several measurements taken on each. Problems of th construction of index numbers, the analysis of economic time series, and population statistics loom large in economics and sociology. Some of the classic problems in time series are the discoveries of trends, the removal of seasonal variations, and the search for periodicities.

**Sequential Analysis.** During World War II, Abraham Wald made a significant contribution to the problem of testing hypotheses by developing the technique of sequential analysis. In sequential analysis one does not work with a fixed sample size, as in the tests described earlier. Observations are taken successively. After each observation one either (1) accepts the null hypothesis, or (2) rejects the null hypothesis, or (3) reserves decision for more evidence. This technique results in the use of a smaller average number of observations to reach a decision. Variations of this technique had been used earlier by anthropologists to decide when to stop collecting data, but the method had no satisfactory mathematical basis.

**Control Charts.** In industrial production, control charts developed by Walter A. Shewhart, are used to decide when to examine the production process. One standard procedure is to set up a chart with two parallel lines each three standard deviations from the mean of the process. At regular time intervals averages of five observations are plotted on the chart. If at any time a point falls outside the control limits the decision is made to search for maladjustments in the process. Lot-by-lot sampling inspection was developed by H. F. Dodge and H. G. Romig.

### HISTORICAL MATERIAL

Statistical inference frequently requires the use of mathematical models. Since many of these models require the use of the concept of probability, the histories of statistics and of probability have much in common. The mathematicians Blaise Pascal and Pierre de Fermat in 1654 worked on the theory of probability in connection with a gambling problem. Early definitions of probability were of the following type: If an event can occur in only one of a number of equally likely ways, $p$ of which may be considered favorable and $q$ unfavorable, then the probability of a favorable event is $p/(p+q)$. Thus, if a fair coin is thrown, the probability of a head is said to be ½, because the coin may come down either heads or tails. However, this definition of probability often presents difficulties because of the concept of "equally likely ways." Sometimes the possible ways appear infinite in number, and frequently it is impossible to evaluate the ratio $p/(p+q)$ in advance.

In 1711, a book by Jacques Bernoulli suggested that probability be applied to moral and economic questions. But Pierre de Laplace in the late eighteenth century made the first real applications in his writings on astronomy and probability. Later, Karl Friedrich Gauss gave considerable impetus to the study of errors as a result of his astronomical researches. Gauss derived the normal curve of errors, $y = e^{-x^2/2}/\sqrt{2\pi}$, and it is often called the Gaussian law, although A. DeMoivre and Laplace had investigated it earlier.

In the social sciences, statistics was advanced as a general technique of investigation by Francis Galton and L. A. J. Quetelet in the nineteenth century. Karl Pearson made substantial applications of statistics to biometry, anthropology, and sociology, and contributed extensively to mathematical statistics in the early twentieth century. Among other contributions, the methods of maximum likelihood and fiducial inference were developed by R. A. Fisher. Fisher also contributed substantially to the advancement of eugenics by application of statistical methods. About 1930, Walter A. Shewhart developed the control chart method of controlling the quality of manufactured products. This development is generally regarded as the first large-scale application of statistical techniques to mass production. In the field of mathematical statistics, Jerzy Neyman and Egon Pearson advanced the study of problems of testing hypotheses and confidence limits. F. Mo.

**STATIUS, PUBLIUS PAPINIUS** [ste′shiəs] (c. 45-95 A.D.), Latin poet born at Naples and poet at the imperial court of Domitian.

From 80 to 92 Statius composed his *Thebaid,* an epic poem of ten thousand hexameters, in twelve books. He also composed five books of *Silvae,* occasional poems rapidly written, nearly all in hexameter, and of various lengths. In antiquity Statius' fame rested largely on his *Thebaid,* but to modern taste the *Silvae* are more appealing. G. McL. H.

**STATUE OF LIBERTY.** *See* LIBERTY, STATUE OF.

**STATUTE OF WESTMINSTER,** an act passed by the British Parliament in 1931 which defined the position of the dominions within the British Commonwealth of Nations. Its chief importance was to give a formal and constitutional basis to relationships recognized by earlier understandings, particularly those of the Imperial Conferences of 1926 and 1930. These conferences, begun in 1887, were informal meetings of colonial and dominion representatives with representa-

tives of the British government to discuss matters of mutual concern. In 1926 W. L. Mackenzie King, Canadian prime minister, went to Great Britain intending to establish the autonomy of Canada. He was supported by South Africa and the Irish Free State. The Balfour Report, which summarized the conclusions of the conference, declared that the dominions were "autonomous communities within the British Empire, equal in status, in no way subordinate one to another in any aspect of their domestic or external affairs, though united by a common allegiance to the Crown and freely associated as members of the British Commonwealth of Nations." The conference of 1930 clarified certain legal points.

The Statute of Westminster specifically provided that legislation of dominion parliaments could not be objected to, even if repugnant to legislative acts of the British Parliament. Furthermore, no British legislation could apply in a dominion unless specifically requested. The act also repealed the Colonial Laws Validity Act, which had been passed in 1865 and which declared that colonial legislation, when in conflict with British legislation, was inferior to it. In reality, the act had not been enforced to any extent for years.

The Statute of Westminster, which has been advanced as the keystone of the arch of Canadian independence, granted little which had not been conceded earlier. In one particular the act was not all-inclusive: it did not stipulate that the parliament of Canada could amend the British North America Act, a British statute, which is the Canadian constitution.

J. J. T.

**STAUNTON** [sta′ntən], an independent city in northwestern Virginia, the county seat of Augusta Co., is situated in the Shenandoah Valley, 98 mi. northwest of Richmond, in a rich agricultural area, for which it is the trade center. The territory is renowned for its grain, apples, and livestock. Coal and building stone are natural resources of the region. Founded in 1736, Staunton was incorporated as a town in 1801 and as a city in 1870. The city's government is the council-manager type. In 1781 during the Revolutionary War the State General Assembly took refuge in Staunton, making it the state capital. During the Civil War, Union forces twice occupied the city. Staunton originated the city-manager, or council-manager, form of government in 1908. The city is the birthplace of Woodrow Wilson, whose home, which was built in 1846, has been restored as a shrine. A national and a Confederate cemetery are near by. The city is the seat of Mary Baldwin College. Transportation is afforded by the Chesapeake Western and the Chesapeake and Ohio railroads. Among the manufactures are men's clothing, furniture, and flour. Pop. 1950, 19,927.

**STAUROLITE** [stɔ′rolait], a mineral named from the Greek word meaning "cross," in allusion to its tendency to occur in cruciform twins. It is a ferrous iron aluminum silicate, $FeAl_5Si_2O_{12}(OH)$. Staurolite almost always occurs in single, flattened, elongate orthorhombic crystals. The color is brown when fresh, and the hardness is 7 to 7.5, but specimens are usually softer due to surface alteration to secondary mica. Staurolite is a typical mineral of regional metamorphism, occurring in staurolite schists. It is not a commercial mineral, except for rare gemworthy specimens and for well-developed twins which have sales value as religious emblems.

K. K. L.

**STAVANGER** [stɑ′vɑŋər], a seaport and fish-processing center, capital of Rogaland *fylke* (county) in southwestern Norway, 185 mi. southwest of Oslo. The city, the fourth largest in Norway, is located on a low rocky peninsula dotted with rounded hills, bordered on the west by the Atlantic Ocean and on the east by Stavanger Fjord, south branch of Bokn Fjord. Stavanger was founded in the eighth or ninth century and incorporated in 1425. Here in the eleventh century the English Bishop Reinald founded a cathedral dedicated to St. Swithin and completed in Gothic style in the twelfth and thirteenth centuries. The city lost its bishopric and much of its importance after the Lutheran Reformation in 1537; the bishopric was restored in 1924. In 1873 the first fish-preserving plant was built, to be followed by many others, which have brought about a commercial revival of the city. Large fish-packing plants and factories producing cans and boxes for this industry are located in Stavanger. During World War II it was the site of landings of the invading German armies in April 1940 and later was bombed by the British. Stavanger has advanced schools and a small museum. The city, connected with eastern Norway by the Jaeren Railway to Oslo, has rapid and frequent sea communications with Great Britain, the Continent, and North America. Southwest of Stavanger is the Sola Airport, started by the Norwegians before World War II and greatly expanded by the Germans during their occupation of Norway (1940-1945). It is considered one of the best-developed and located airports of western Europe and the strategic air center of the North. Pop. 1952, 50,888.

J. E. V.

**STAVESACRE** [ste′vzekər], an erect, downy, annual herb, *Delphinium staphisagria,* of the crowfoot family, native to southwestern Europe and Asia Minor. It grows as high as 4 ft. and has palmately divided leaves and terminal spikes of bluish flowers. The poisonous seeds, containing delphinine and other alkaloids, are used medicinally and in insecticides.

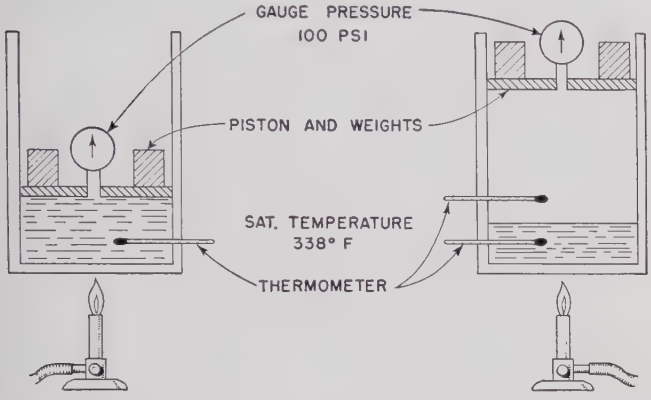
J. C. Wis.

**STEAM,** the gas or vapor form of water, chemically identical with liquid water. Contrary to the popular conception, it is invisible; the visible cloud issuing from a boiling kettle is a large number of very fine liquid drops of water carried along by the steam. The thermal properties of steam, which are defined here, make it an extremely important agent in maintaining life on the earth and in providing for the comfort and progress of man. It is well known, for instance, that heat from the sun is absorbed by the sea to form water vapor (steam) which rises into the atmosphere and is there condensed to form the clouds for rain and snow.

Evaporation, or vaporization, is the physical and thermal process that signifies the change of a liquid to a vapor, and condensation is a similar process in the reverse order.

To describe vaporization and the attendant physical and thermal properties, consider one pound of liquid water contained in a glass cylinder fitted with a piston, pressure gauge, and thermometer (*See* Fig. 1). The piston, which is free to move upward, is loaded with weights until the gauge reads a pressure of 100 lb. per square inch in excess of the atmosphere (gauge pressure); and the total pressure in the water is 115 lb. per square inch absolute. If heat is now applied, vaporization will begin at the saturation temperature, 338° F. (*See* table). With further heating, the saturated liquid water vaporizes to steam; the piston moves upward as shown in Fig. 2, and the temperature and the pressure remain unchanged. At this pressure, the heat of vaporization or amount of heat required to change one pound of water (from 338° F.) to one pound of saturated steam at 338° F. is 881 B.t.u. (*See* table). Again referring to the table, the one pound of water which occupied a liquid

volume of 0.0178 cu. ft. expanded 218 times to a steam volume of 3.88 cu. ft. If this experiment is repeated many times with increasing pressures, the expansion from liquid to vapor and the heat of vaporization will be observed to decrease to zero at the critical pressure, 3,206 lb. per square inch absolute. Also, the temperature required for vaporization will have increased to the critical temperature, 705° F.



*Figs. 1 & 2 (LEFT AND RIGHT, RESPECTIVELY)—THERMAL PROPERTIES OF STEAM*

In the first experiment, if the remaining liquid water were dispersed as small drops throughout the steam space before vaporization was complete, the steam would be called wet. Conversely, if all liquid water is converted to vapor, the steam is said to be dry. These conditions are represented by the quality, with dry steam indicated by 100 per cent. The quality cannot exceed 100 per cent, since further heating of dry steam will cause the temperature to rise above the saturation temperature, whereupon the steam is said to be superheated. The amount of this temperature rise is reported as the number of degrees of superheat.

PROPERTIES OF STEAM*

*Data obtained from J. H. Keenan and F. G. Keyes, *Thermodynamic Properties of Steam*, 1st. ed., 1936, New York.

†Standard atmospheric pressure, 14.696 lb. per square inch absolute, and 29.992 in. of mercury, or approximately 15 and 30, respectively.

## SUPERHEATER

A superheater is a vapor-heating apparatus, most commonly used to increase the temperature of steam above its normal boiling point. A high-temperature superheated steam is required for economy in the performance of steam engines and turbines, the steam consumption being reduced about 1 per cent for each 10° F. of superheat. The upper limit of temperature is determined by the heat-resistance properties of the machines and materials rather than the advantages of improved performance. In the period from 1905 to 1950 the highest superheat steam temperature was increased from 550 to 1,050° F., 950° F. being widely used in large power plants after 1938.

The apparatus is constructed of steel tubing forming a heating surface for the steam that flows within it. Saturated steam from the boiler enters the tubing at one end and is heated to the desired outlet temperature by heat applied to the outside surface. Compared with the boiler heating surface, the superheater tubing surface area will vary from about one-half, for moderate temperatures, to twice that of the boiler for high steam temperature.

**Types.** Although the superheater may be of the separately fired type, that is, an independent furnace containing the superheater only and connected to a boiler, the large majority are built into the steam generator. These integral superheaters are of two general classes: radiant and convection. Other names, such as interpass, interdeck, overdeck, intertube, and interbank, are used to describe the position of the superheater with respect to the principal boiler heating surface. One square foot of the surface of the radiant-type superheater, which is located to receive radiant heat from the combustion zone of the steam-generator furnace, will transfer from two to three times as much heat as that for the convection type. The convection superheater, located in the higher-temperature regions of the boiler gas passages, depends upon convection heat or the heat obtained from the flow of hot gases passing over the tube surface.

**Controls.** Since the steam pressure is usually the maximum permissible, superheater controls are provided to maintain the desired temperature (within —10° F.) for the operating range of steaming rates of a particular steam generator. It is characteristic of superheater performance that the steam temperature from the radiant type will decrease as the steaming rate or load increases, whereas that for the convection type increases. This behavior is used in one method of control, in which both types installed in series form a combined superheater that limits the amount of temperature variation. A gas by-pass or damper-controlled system is most often used. It diverts a fraction of the hot gases around a convection-type superheater to lower the steam temperature. Other methods include the differential control of firing rates where permitted, as with multiple burners in the furnace; twin furnaces or separately fired superheaters; and the attemperator or desuperheater control, in which the superheated steam is cooled by contact or liquid water spray.

## STEAM GENERATOR

A steam generator includes equipment or apparatus for producing water vapor, or steam, from liquid water. Thus, the boiler is a steam generator. However, the term usually denotes a boiler with one or all of the following associated equipment: superheater, economizer, air preheater, steam reheater, and such auxiliaries as are necessary for satisfactory operation of the unit. Generation of the steam required to produce power is a major industry, considering that the use of steam is predominant for railroad and marine power plants, and represents about two-thirds of the electrical energy produced by utility and industrial plants of the United States. Development of the steam generator since the middle 1920's

has resulted in increased steam capacity, pressure, temperature, and economy, as a result of improved materials and methods and the effective use of heat-recovery apparatus. Sustained commercial operation has been obtained with single units at over 800,000 lb. of steam an hour, 1,250 lb. per square inch pressure, 950° F. temperature, and an average 85 per cent over-all efficiency.

The steam generator is designed or modified to meet the economic requirements of every installation. This is particularly true for the largest central station power plants for which steam generators are built to order. Some of the more important factors that must be considered are the type of fuel, whether solid, liquid, or gas; the firing methods and physical characteristics, particularly of solid fuels; steam pressure and temperature; suitability of feed water; maximum continuous and peak steaming capacities; available space for installation; monetary value of increased efficiency; and required reliability of operation. H. A. J.

## STEAM ACCUMULATOR

A steam accumulator is an apparatus for storing heat energy in steam when supply exceeds demand, rendering it available for later use. It is, in effect, a steam flywheel, It is connected between two steam systems, one at higher pressure than the other, to store up heat from the higher pressure system and deliver it to the lower pressure system to supply peak loads. This arrangement permits the higher-pressure system to operate at constant pressure and load, a condition that is always best for boilers.

**Capacity.** Most accumulators are insulated steel tanks, welded or riveted, from 6 or 7 ft. to 15 or 16 ft. in diameter and from 15 to 60 ft. in length, with water capacity from 200 to 15,000 cu. ft. They are usually about nine-tenths full of water. The capacity in steam storage depends on the supply and discharge pressures and temperatures, which determine the heat drop. In one installation, a 16 by 55-ft. accumulator had a storage capacity of 45,000 lb. of steam between 90 and 15 lb. per sq. in. pressure.

**Theory.** Steam from boiler or boilers at high pressure is fed into the water, which condenses the steam by direct contact and absorbs heat from it. Then, if there is a demand for steam at the lower pressure, the pressure in the accumulator is lowered and the heat already absorbed in the water will cause 20 to 40 per cent of the water to evaporate into steam at the lower pressure. This steam is withdrawn to meet the low-pressure peak demand. This process lowers the temperature of the water in the tank, which can then condense more high-pressure steam. Automatic control valves on the steam-admission and steam-withdrawing pipe lines adjust the flows of steam, to proportion the required steam flows from boiler and accumulator to the steam-using equipment.

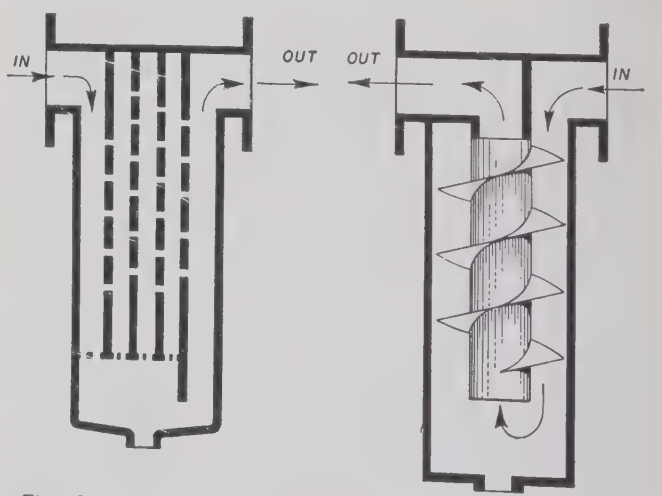
For example, if the pressure in a tank of water or in a steam boiler is 415 lb. per sq. in. and the pressure is decreased to 325 lb. per sq. in., then 1.7 lb. of steam will be released from each cubic foot of the water. If the original pressure were 150 lb. per sq. in. and if it were decreased to 75 lb. per sq. in., each cubic foot of water would produce 3.7 lb. of steam. The amount of steam released per cubic foot of water depends on the average density of the water in pounds per cubic foot (the density varies with pressure and temperature) and also on the difference in heat between the upper and lower pressure and temperature limits.

**Applications.** From 1918 to 1928, the steam accumulator was developed and applied extensively in Europe by the Ruths Accumulator Company, Inc. In 1928 there were 317 installations by that company in Europe and 16 in the United States. The accumulator principle, however, had been used earlier in Europe by C. H. Smoot. Rateau accumulators were also installed in the United States, principally in connection with gas works. By 1928, the Kiesselbach constant-pressure accumulator had also been developed. In this apparatus, heat in steam is stored in water, but hot water is delivered by the accumulator instead of steam, the pressure in the accumulator always remaining essentially constant.

Engineers in the United States have not applied the steam accumulator extensively. When it was first developed, boilers and firing equipment were relatively inflexible in serving fluctuating loads and could attain maximum efficiency only at a very short, high range of output. Since about 1930, however, boilers and firing equipment have been developed that can maintain satisfactory fuel economy over the ranges of steam demand which occur in most industrial processes. Pulverized-coal firing, new types of stokers, and wide-range oil and gas burners have made this improvement possible. Automatic combustion controls, which have also been brought to a high degree of perfection, help to maintain good fuel economy over wide ranges of boiler output. For these reasons and many others, the need originally met by the steam accumulator is now generally met by the boiler itself; or, in exceptional cases, the boiler may be especially designed to supply its own accumulator effect.

## STEAM SEPARATOR

A steam separator is a device for removing droplets of water from steam flowing in a pipe, so that steam alone will reach the consuming apparatus. The droplets of water may be in the steam when it enters the pipe but, even if the steam is dry, some condensation will occur. This is because it gives up some of its heat to warm the pipe; and, at the same time, even if the pipe is insulated, a small but appreciable heat loss will occur through the insulation, since it is uneconomical to attempt perfect insulation.



*Figs. 3 & 4* (LEFT AND RIGHT, RESPECTIVELY)—FORMS OF STEAM SEPARATORS.

Fig. 3: *Baffle type;* Fig. 4: *Centrifugal type*

The water of condensation, termed condensate, formed by the water droplets carried in the steam, prevents the steam from transmitting its heat most efficiently in the steam-consuming apparatus. Also, if in some way water were to accumulate in a pocket in the steam line and be forced along

at high velocity, it would form a water hammer, striking valves, pipe fittings, and other equipment with sufficient force to break them.

To dry the steam, it is customary to use separators just ahead of the steam-consuming apparatus. These remove the droplets, or masses of water, and allow the dried steam to pass on. One form of separator, as in Fig. 3, gives a sudden change in direction to the steam. The heavier particles of water try to go straight ahead, but strike the baffles and flow down to a sump at the bottom of the separator. Another form of separator (Fig. 4) imparts a whirling motion to the steam, and throws the moisture particles away from the steam flow, so that they collect on the separator sides and fall to a sump or collection chamber at the bottom. In both instances, the water space at the separator bottom is drained through a steam trap, which allows the water to flow out, but not steam.

In one form of separator, the baffles shown in Fig. 3 are replaced by a fine-mesh screen. Other types use a porous stone to absorb the moisture in the steam, letting it drip into the sump, while still another type directs the steam flow through a felt pad which absorbs the moisture. Gridiron plates are also used in some instances to collect the moisture. The most commonly used types, however, are those which utilize a change of direction, plus baffles of some kind, or those which employ whirling action, or a combination of the two.

## STEAM TRAPS

Steam traps are automatic valves used to allow draining of condensate, and sometimes air, from closed steam spaces at the rate at which the condensate forms. Condensate is the water formed when steam in a closed space gives up heat to some other substance surrounding, or enclosed in, the steam space—as in an ordinary steam radiator, a heating coil, or a jacket on a process kettle. Condensate must be properly drained as formed, so that the steam can continue to flow fast enough to supply the required amount of heat. The steam trap is only a controller; it does not drain condensate, but merely recognizes the arrival of steam or condensate. It closes to prevent waste of steam, and opens to allow the steam pressure to push the condensate through for further disposal. Traps are of these fundamental types: mechanically operated (bucket or float); thermostatically operated; labyrinth or orifice type.

The mechanically operated trap depends for operation on filling of a bucket with condensate, as in the open-top bucket trap, to furnish power for opening the valve; or on the buoyancy of a float. Some depend on the difference in weight between condensate and steam, as in tilting traps, in which the condensate accumulation tilts the trap body around a pivot and opens the valve. Some float trap mechanisms are relays, operating a separate steam valve to admit steam and force out the condensate.

Thermostatic traps operate on the principle that a tube, or bellows, when in contact with condensate, holds the valve open and the steam forces the condensate out through the valve. However, as hot condensate and steam reach the tube or bellows, it expands, closing the valve. In one type, an expanding liquid in a jacket outside the tube provides the force for closing the valve.

The labyrinth type employs several expansion chambers or orifices, through which steam expands with increase in volume, closing the valve, whereas condensate flows through at constant volume. In the impulse trap, two orifices, a chamber between, and a small passage through the valve, are all proportioned so that, as condensate increases, pressure builds up under the valve, which lifts and discharges condensate, but closes when steam arrives.

Several types of pumping traps, lift traps, and boiler feed return traps employ various combinations of the above fundamental principles. C. R. E.

## STEAM CALORIMETER

A steam calorimeter is a device used for the determination of the quality of wet steam. Wet steam is a mechanical mixture of small drops of liquid water and gaseous water vapor. The proportion of gaseous water vapor in the mixture may vary and is expressed in terms of quality, the extreme limits being 0 per cent quality (all liquid) and 100 per cent quality (all gaseous). Between these limits, and at a given pressure, the temperature is the same for all qualities, so that simultaneous measurements of pressure and temperature, alone, are not sufficient to determine either the quality of the steam or the values of other properties such as specific volume, entropy, or enthalpy. The steam calorimeter, however, furnishes a means of determining the quality of a mixture and, from this, the values of all other properties. It is, therefore, a most important instrument in the testing of engines or other equipment using nonsuperheated steam.

**Operation.** All calorimeters require that steam be drawn from the test source at a low constant rate, usually of the order of 75 lb. per hr. This sample is then subjected to either a drying or superheating process, and then discarded at a pressure slightly above atmospheric. Separating calorimeters dry the steam sample, while throttling and electric calorimeters cause the steam sample at discharge to be slightly superheated.

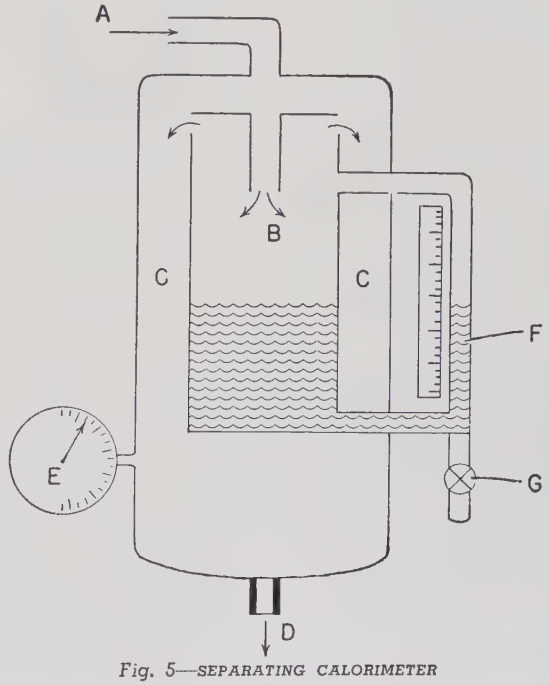


*Fig. 5—SEPARATING CALORIMETER*

*Separating Calorimeter.* Fig. 5 shows a cross section of a separating calorimeter. Steam entering at *A* flows into chamber *B* at high velocity. The inertia of the dense liquid droplets causes them to impinge on the sides of the chamber and to collect in a little pool, as shown. The much less dense vapor, however, reverses its direction and passes through an annular space around the inlet nozzle, and then into the jacket space *C*. The dried steam sample then escapes to the atmosphere through the calibrated outlet orifice *D*.

The quality of the steam entering chamber $B$ may be calculated from the expression:

$$x = \frac{W}{w + W} = \textit{Quality (in per cent)},$$

where $W$ equals the rate of flow of dry steam through nozzle $D$, and $w$ equals the rate at which liquid water collects in chamber $B$. Nozzle $D$ is calibrated in terms of readings of pressure gauge $E$. The water level glass $F$ is fitted with a scale calibrated in pounds and has a drain $G$. The entire exterior of the device is highly polished to minimize heat loss by radiation. Orifices of various sizes may be used for the discharge $D$, the size being selected so that the rate of flow $W$ is sufficiently large to make unnecessary the correction of $W$ for radiation losses. The rate of accumulation $w$ of water in chamber $B$ is determined by timing of the level change, while the rate of steam discharge, $W$, is computed from the pressure gauge reading and from the calibration equation for the discharge orifice.

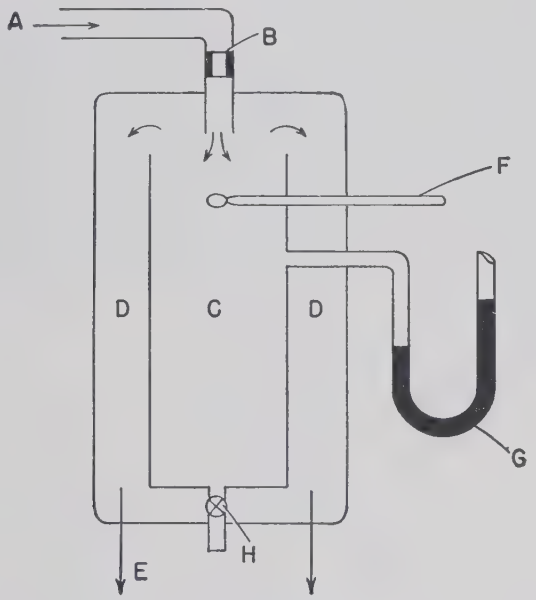

*Fig. 6—THROTTLING CALORIMETER*

*Throttling Calorimeter.* Fig. 6 shows the cross section of a throttling calorimeter. Steam enters the device at $A$ and passes through orifice $B$ into chamber $C$, and then through jacket $D$ to atmospheric discharge $E$. The enthalpy of the steam at $C$ is the same as that at $A$, but the pressure at $C$ is practically atmospheric. If the quality of the steam at $A$ is not too low, the steam at $C$ will be superheated, in which case simultaneous measurements of pressure and temperature in chamber $C$ will determine the thermodynamic state of the steam there. The quality of the steam at $A$ is determined by equating the enthalpy at $A$ to that at $C$. The enthalpy at $C$ can be evaluated directly since the amount of superheat has been measured. The exterior surface of this type of calorimeter is plated and polished to minimize the rate of heat loss by radiation. Also, the orifice $B$ is replaceable in various sizes. The size of orifice selected should be such as to insure a flow rate sufficiently high to keep heat losses from the jacket negligibly small as compared to the total enthalpy of all steam flowing through chamber $C$. Other parts of this calorimeter are: thermometer $F$, pressure manometer $G$, and drain valve $H$.

*Electric Calorimeter.* The electric superheating calorimeter resembles the other types in outward appearance. Inside, this type includes an electrically-heated channel. In operation, steam enters the heating section from an orifice so that the pressure in the heating section is atmospheric. The heating units are supplied with power sufficient to cause the steam to be superheated at the outlet. Measurements required include the temperature and pressure of the steam at outlet, the power used by the resistance, and the pressure of the steam before the metering orifice. The calculation for obtaining the initial enthalpy of the steam is based on a heat balance in which the heat added electrically is equated to the change in enthalpy required for drying and superheating the steam to its final condition.

**Use.** The throttling calorimeter is the most widely used device for evaluating quality. This is logical since it is the simplest of the three to operate and also because its narrow range of utility (qualities of 96 to 100 per cent) coincides with the range of steam qualities normally encountered.

*Error in Use.* The source of most error in the determination of steam quality is in the quality of the steam sample entering the calorimeter not representing the average quality of all the steam passing the sampling point. If the direction of flow of the steam is horizontal at the sampling point, the water droplets may fall to the bottom of the pipe, and if the direction of steam flow is vertically downward, the water droplets may cling to the walls and flow downward in small streams. Therefore, it is standard practice to locate the sampling point in a comparatively long vertical pipe in which the steam is flowing upwards. A standard sampling tube is also used in an effort to make certain that the steam sample represents the average quality to be found along any radius of the pipe at the sampling point. Specifications for sampling tubes may be found in the test codes which apply.

E. D. H.

## STEAM ENGINES

Steam engines are reciprocating piston prime movers which convert the heat and pressure energies of steam into mechanical work. Externally generated steam is piped to the engine valve chest (steam chest). The valve admits a charge of steam to a cylinder at the proper position of a piston. The pressure of the steam on the piston forces the piston to move and to produce mechanical work thereby.

**History.** The modern steam engine, in its multiplicity of forms, is an aggregate of inventions. The ancients recognized the potential energy of water when turned into steam by the application of heat. The first record of an approach to the useful employment of this energy appears in *Pneumatica,* by Heron of Alexandria, who lived about the second century, B.C. Heron sketched and described devices such as "a fountain which is made to flow by the action of the sun's rays." In his contrivance, a spherical vessel was mounted over a closed tank, with a pipe from the bottom of the tank to the top of the sphere. A second pipe, in the form of a siphon, led from the bottom of the sphere to a basin. The tank and sphere were partially filled with water. The sun's rays heated the water in the sphere to form steam, which forced water from the sphere through the siphon to the basin. At night the sphere cooled, the steam condensed, and water was drawn up into the sphere from the tank by the partial vacuum so produced. No mention was made of the necessary valve in the siphon pipe for such a filling action to occur. This device was the forerunner of the steam pump and steam engine.

Not until the sixteenth century do writings appear that further hint at the knowledge of the properties of steam and of the advantages of its application to perform work. Jacob

Besson, in 1569, and Agostino Ramelli, in 1588, wrote of the properties of steam, and of machines and mechanisms designed to utilize those properties. Leonardo da Vinci described a steam gun, in which the steam was generated in the gun chamber by permitting water to fall on a heated surface. The sudden expansion of the water into steam would serve to eject a ball from the chamber.

*Early Engines.* In 1601, Giovanni Battista della Porta described a water-raising device that made use of the pressure of steam to cause a water outflow from a chamber, and also of the vacuum created by condensation of the steam to cause an inflow of water. Della Porta is also credited with the first separation of the forcing vessel, or engine, from the steam generator, or boiler. About 1628, Edward Somerset, Marquis of Worcester, invented the first large-scale application of the steam engine. His machine was designed to raise water. In operation, it was essentially the same as Della Porta's engine with an external steam boiler, suitable piping, and valves.

At the end of the seventeenth century, English mines had become so deep that their drainage became a major problem. The development of the steam engine was given added impetus by this need. Thomas Savery, in 1698, patented the first engine that was actually employed for this work. To some extent, it was also used to supply towns with water, so that Savery is credited with the first machine to use the power of heat for general utility. His engine was similar in principle to Somerset's. It was modified by others to improve its performance, but its large size and operational difficulties prevented its widespread application. Up to this time, the engines used the steam directly in the water. Christian Huyghens, in 1680, had proposed a gunpowder engine using a piston. Denys Papin, in 1690, used the piston in a steam engine but did not perfect the invention as a continuous source of power.

Thomas Newcomen, in 1705, patented a steam engine consisting of a steam cylinder containing a piston similar to that of Papin's, and driving a separate pump (*See* Fig. 7).

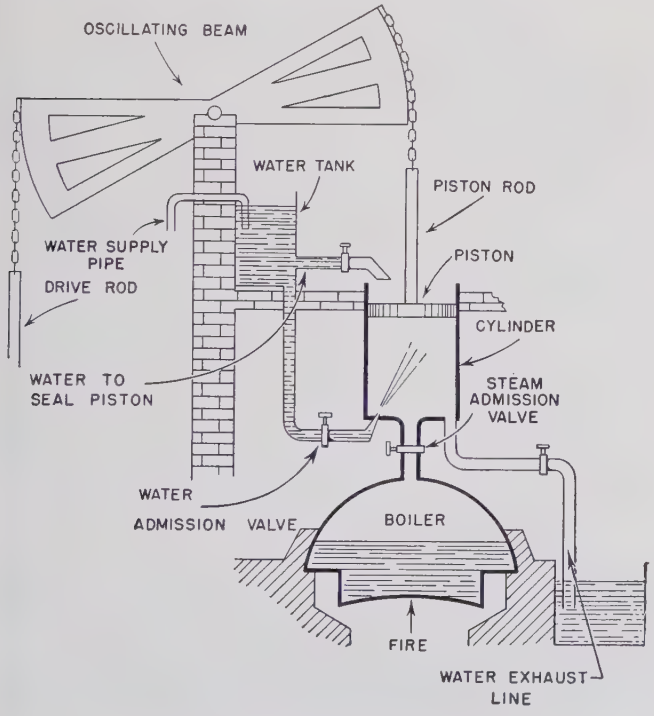

*Fig. 7—THE NEWCOMEN STEAM ENGINE*

Steam was admitted to a cylinder to raise the piston. A jet of water was then sprayed into the cylinder to condense the steam and to create a vacuum. Atmospheric pressure then forced the piston downward. The piston motion was transferred to a separate pump by an oscillating beam. This engine, with modifications of the mechanism, was adopted extensively in all British mining districts and was also used in mills and water-supply systems.

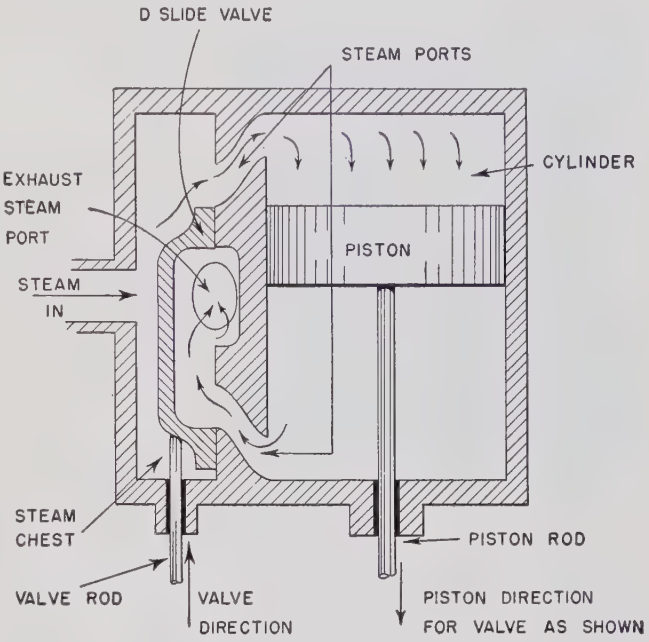

*Fig. 8—BASIC PRINCIPLES OF THE MODERN, D-VALVE, DOUBLE-ACTING STEAM ENGINE*

*Watt's Contributions.* James Watt applied scientific reasoning and experimentation to the engines of Newcomen to develop means to increase their effectiveness and efficiency. The introduction of water into the cylinder of the Newcomen engine cooled the cylinder and walls to such an extent that some of the energy of the next charge of steam was used to reheat the walls without performing useful work. Watt, in 1764, devised the external condenser, together with other improvements. A decade later, he produced the first engine of the modern type. His achievements also included the double-acting steam cylinder, in which steam acted alternately on both sides of the piston; the noncondensing engine, which used no condenser but exhausted the steam to the atmosphere; and the double-cylinder or compound engine, in which steam was admitted to one cylinder. In this cylinder, only part of the energy of the steam was used. The steam was then passed to the other cylinder for further utilization of the energy.

Developments from the time of Watt have been in refinements of the Watt engine. The basic principles (*See* Fig. 8) and mechanisms have not changed.

## CLASSIFICATION

Steam engines are designated according to speed, cycle, mechanical features such as valves and cylinder arrangement, use, and power rating.

**By Speed.** Because of the large masses of the reciprocating parts, the speeds of the engines are limited. High-speed engines operate in the range of from 300 to 500 revolutions per minute, moderate-speed from 100 to 200 r.p.m., and slow-speed from 60 to 90 r.p.m.

**By Steam Cycle.** The energy of the steam may be utilized in the cylinder in one of two basic cycles. Nonexpansion engines (*See* Fig. 9) admit steam at line pressure to the cylinder at the top of the piston stroke. The full steam pressure is maintained on the piston to the bottom of the stroke. Such engines are relatively inefficient, since the energy of expansion of the steam is not used. The work output per piston stroke is a maximum in this cycle. Small engines for intermittent operation, where economy is not important, use this cycle.

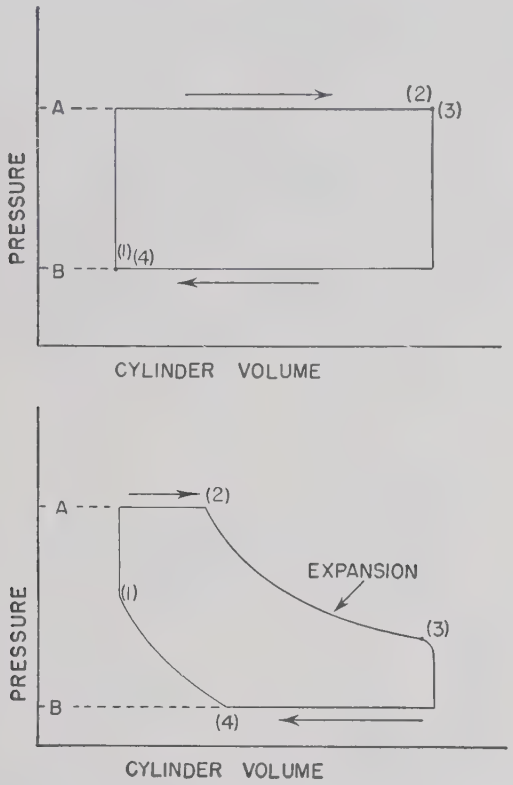

*Fig. 9—STEAM CYCLE DIAGRAMS: (TOP) NON-EXPANSION ENGINE CYCLE; (BOTTOM) EXPANSION ENGINE CYCLE*

*(A) Steam pressure; (B) Exhaust pressure; (1) Inlet valve opens; (2) Inlet valve closes (cutoff); (3) Exhaust valve opens (release); (4) Exhaust valve closes. (Arrows indicate direction of piston movement.)*

The expansion engine (*See* Fig. 9) is used for greater economy or efficiency. The steam supply to the cylinder is cut off when the piston has traveled approximately one-fourth to one-third of its stroke. The trapped steam then expands in the cylinder, and this energy is utilized to drive the piston the remainder of the stroke. The steam is usually released at a pressure somewhat higher than the discharge pressure. This method reduces excessive cooling of the cylinder walls due to the drop in temperature on expansion and also reduces the over-all size of the engine.

In condensing engines the steam is exhausted to an external condenser to condense the steam for final removal from the circuit in the form of water. With this feature the exhaust pressure may be less than atmospheric to effect a gain in the expansion energy release. Noncondensing engines exhaust directly to the atmosphere.

**By Valves.** The steam-engine valve controls the admission and rejection of steam to the cylinder. In the slide-valve engine both operations are performed by the same valve. The D valve, or piston valve, actuated from an eccentric on the engine crank, oscillates in the steam chest to uncover ports in the cylinder walls. The same ports are used for admission or exhaust of the steam. The colder exhaust steam cools the region around the ports and the hot entering steam reheats the wall with a consequent loss of energy of the steam.

In 1908, Johann Strumpf invented and patented the uniflow engine (*See* Fig. 10). A single steam valve in the cylinder head admits steam to the cylinder. Exhaust takes place at ports in the middle of the cylinder when the piston uncovers these ports. The thermal performance of the engine is better than that of the slide-valve type, since the working parts are kept at essentially the same temperature and initial condensation is reduced.

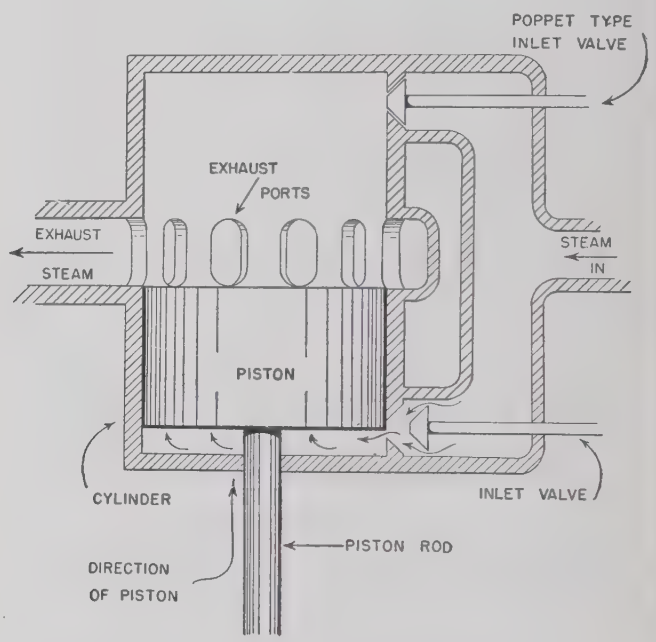

*Fig. 10—DOUBLE-ACTING UNIFLOW ENGINE*

**By Cylinder Arrangement.** To reduce the temperature difference between the inlet and exhaust steam in any one cylinder and to reduce the single-cylinder size, compound or multiple-expansion engines are used. Steam enters one cylinder, where some of the energy is removed; the steam then passes to a second cylinder, in which the steam is further expanded. All cylinders drive a common crank. Quadruple-expansion engines (four cylinders) have been built.

**By Use.** Stationary engines are used to drive generators, pumps, or other mechanisms. Steam engines for stationary applications of over 500 horsepower have been largely superseded by the steam turbine with its higher rotation speeds, smaller size, and greater efficiency.

The steam-line throttle-valve opening may be positioned by hand for variable-speed steam-engine operation. The engine may also be reversed by suitable mechanisms on the valve linkage. These features are necessary for locomotive and ship operation.

A quadruple-expansion marine steam engine of 20,000 hp. was built in 1900. Until 1920 the steam engine was the most common type of prime mover in marine service. Since then, the steam turbine and diesel engine have largely displaced the steam engine in marine applications. However, during World War II, triple-expansion steam engines of 2,500 hp. were installed in the emergency Liberty ships. *See also* EN-

**STEATOPYGIA** [sti'ətopai'jiə], an anatomical characteristic found in its most extreme form as a racial trait of the Bushman-Hottentot. It consists of an excessive accumulation of fat localized largely in the buttocks, making them distinctly protuberant. Prehistoric figurines found in Europe displaying this peculiarity have suggested to some scholars the possibility that the Bushman stock once inhabited southern Europe. H. L. Sh.

**STEDMAN, EDMUND CLARENCE** (1833-1908), American poet, critic, and essayist, was born Oct. 8, 1833, in Hartford, Conn. Expelled from Yale in 1852, he became a journalist and was war correspondent for the *New York World* in 1861. From 1869 to 1900 Stedman was a member of the New York Stock Exchange, doing literary work in his spare time. Representative of his verse are his first volume, *Poems Lyrical and Idyllic* (1860), *Alice of Monmouth* (1864), and *The Blameless Prince* (1869), which contained his best-known poem, *Pan in Wall Street.* His chief anthologies are *An American Anthology* (1900); and *A Library of American Literature,* which appeared in 11 volumes between 1887 and 1890, and which he edited with Ellen M. Hutchinson. His leading critical works are *The Victorian Poets* (1875); *The Poets of America* (1885); and *The Nature and Elements of Poetry* (1892). He was the foremost American critic in an age that admired the genteel tradition. He died in New York on Jan. 18, 1908. A. La.

**STEEL.** *See* ENGINEERING MATERIALS; IRON AND STEEL.

**STEELE, SIR RICHARD** (1672-1729), British essayist and playwright, was born probably on March 12, 1672, in Dublin, Ireland. Steele began his schooling in 1684 at Charterhouse, where he met Joseph Addison, whom he followed to Oxford in 1689. Not waiting for a degree, Steele entered the army in 1694, rose to a captaincy by 1700, and left the army about 1705.

Steele's literary career began with the publication of *The Christian Hero* (1701), written to prove "that no principles but those of religion are sufficient to make a great man." Turning to drama, he wrote *The Funeral, or Grief à-la-Mode* (1701), *The Lying Lover, or the Ladies' Friendship* (1703), and *The Tender Husband; or, the Accomplished Fools* (1705). Having become co-manager of the theatre in Drury Lane in 1714, he produced his best example of the sentimental comedy, *The Conscious Lovers,* in 1722. Though Colley Cibber's *Love's Last Shift* (1696) pioneered in sentimental comedy, Steele, in his efforts "to chasten wit, and moralize the stage," distinctly contributed to the reformation of manners by painting vice in its true colors and depicting virtuous characters worthy of emulation.

In a sense anticipated by John Dunton and Daniel Defoe, Steele, appointed Gazetteer (1707), entered the field of the periodical essay with *The Tatler* (1709-1711), under the editorial pseudonym of Isaac Bickerstaff, Esq., and was joined by Addison in the eighteenth number of the tri-weekly publication. *The Tatler* was followed by *The Spectator* (1711-1712), published six days weekly, and *The Guardian* (1713). Later periodicals started by Steele never achieved the success of his first two ventures. In the periodical essays, Steele and Addison preached the genial gospel of good sense, good taste, and good manners to a cultivated few and to a middle-class group of readers who frequented the coffee houses in London and were rapidly gaining economic and political significance. Steele, not so learned as his friend Addison,

*SIR RICHARD STEELE*

COURTESY OF THE NEW YORK PUBLIC LIBRARY

with whom he later quarreled, was a man of varied tastes and broad sympathies. He attacked duelling, cruelty to animals, and the stupidity and cruelty of schoolmasters; he preached child welfare and praised domestic felicity; he argued for female education and delineated superbly the characters of the Spectator's Club. His essays on virtue in distress were suggestive to the sentimental novelists who followed him. Mention should also be made of his love letters to his wife, "Dear Prue," which are among the finest in English. Predeceased by his wife, Steele died at Carmarthen, Wales, on Sept. 1, 1729. H. Dr.

**STEELE, WILBUR DANIEL** (1886- ), American author, was born in Greensboro, N. C., Mar. 17, 1886. He was educated at the University of Denver, where his father was professor of Biblical literature, and after his graduation in 1907, studied art at the Museum of Fine Arts in Boston, Mass. From 1908 to 1909 he attended the Académie Julian in Paris, and in the following year he studied at the Art Students League in New York. Settling in Provincetown, Mass., in 1910, he gradually abandoned his career as a painter to pursue his interest in writing, and his first success in this field was with the publication of the story *A White Horse Winner* in the *Atlantic Monthly* in 1912. During World War I he was a naval correspondent. He has traveled and lived in the West Indies, Bermuda, North Africa, France, and England.

His first novel, *Storm,* was published in 1914 and was followed by six other full-length novels: *Isles of the Blest* (1924), *Taboo* (1925), *Meat* (1928), *Sound of Rowlocks* (1938), *That Girl from Memphis* (1945), and *Diamond Wedding* (1950). He has also written some one-act plays, collected in *The Terrible Woman* (1925). In collaboration with his wife, Norma Mitchell, he wrote the full-length plays *Post Road* (1934), which had a successful run on the New York stage, and *Penny* (1937); and with Anthony Brown he wrote the play *How Beautiful with Shoes* (1935), adapted from his story of the same name. Steele is, how-

ever, best known as a short-story writer. He has been five times a winner of the O. Henry Memorial prizes: in 1919 he was awarded second prize for the story *For They Know Not What They Do;* in 1921 he received a special award for maintaining the highest level of merit for three years among American short-story writers; in 1925 he tied with Julian Street for first honors with the story *The Man Who Saw Through Heaven;* and in 1926 and 1931 he again took first prize with the stories *Bubbles* and *Can't Cross Jordan by Myself.* In addition he won the fourth *Harpers Magazine* short-story contest with his story *When Hell Froze.* His short stories have been collected in *Land's End* (1918), *The Shame Dance* (1923), *Urkey Island* (1926), *The Man Who Saw Through Heaven* (1927), *Tower of Sand* (1929), and *The Best Stories of Wilbur Daniel Steele* (1946). His stories, usually laid in New England or South Carolina, reveal a bent for the horrifying and the terrible, pursued with rare ingenuity and distinction. C. W. D.

**STEELHEAD.** *See* Rainbow Trout or Steelhead.

**STEELTON,** a borough in Dauphin Co., in south central Pennsylvania, situated on the Susquehanna River, 3 mi. southeast of Harrisburg. Freight facilities are provided by the Steelton & Highspire, the Pennsylvania, and the Reading railroads. Steel and cigars are the chief manufactures. Steelton, formerly known as Baldwin, was incorporated in 1880. Pop. 1950, 12,574.

**STEEN, JAN HAVIKSZ** [ste'n] (1626-1679), Dutch genre painter, was born at Leyden in 1626. He studied at Utrecht under Nicolas Knupfer, at The Hague under Jan van Goyen, and at Haarlem under Adriaen van Ostade. He entered the painters' guild in Leyden in 1648. He is known to have managed a brewery in Delft from 1654 to 1660; he lived in Haarlem between 1661 and 1669; and he ran a tavern in Leyden from 1669 until his death. Steen revealed in his paintings a superb sense of humor and an awareness of the anecdotal and whimsical in human relations. Focused upon lower middle-class family life, most of the five hundred odd paintings ascribed to him present scenes of common occurrence in the family living-room, the kitchen, or the town tavern. Occasional biblical, mythological and historical subjects he almost invariably interpreted as local, current events. His deft compositional arrangement and coloration did not consistently match his descriptive ability, but at its best his tonal scheme is excellent, usually featuring warm yellow and red costumes contrasted with blue and enlivened with touches of reflected highlights. He died at Leyden, Feb. 3, 1679. R. A. K.

**STEEPLECHASING,** the racing of horses over a course beset with fences, walls, brooks, hedges, and other obstacles that a horseman might encounter riding cross-country. The sport originated in Ireland in the eighteenth century and is an outgrowth of foxhunting. During the course of a season's pursuit of the fox across the banks, walls, and ditches of the Emerald Isle, it was quite natural that the bolder horsemen should drift into arguments about the speeds of their respective mounts. These arguments frequently evolved into challenges and match races across country to a prominent landmark, usually a church steeple.

**Steeplechasing Abroad.** The first steeplechase of which an authentic record survives was run in 1752. Another account tells of a race run in 1792 which appears to be the first steeplechase in which more than two riders competed. The first organized steeplechase, however, was not run until 1830, and its success did much to establish the popularity of this form of horse racing.

The Grand National, which for more than a hundred years has been the most famous of all steeplechases, was first run at Aintree, near Liverpool, on Feb. 29, 1836. In 1839, sponsorship of the race was taken over by a company headed by the Earl of Derby, Lord Sefton, and others, and the first race run under these auspices, known as the Grand Liverpool Steeplechase, was run on Feb. 24, 1839. At present the race at Aintree is four miles, 856 yards in length, with thirty jumps, some of spruce, others of fir, and many of them in combination with ditches and brooks. The jumps vary in height from four feet six inches to five feet two inches. The Grand National offers the largest purse of any steeplechase in the world, the value to the winner usually approximating $40,000. Because the stake is so high and the title so coveted, the Grand National attracts a large field (66 in 1929) of the finest-bred and fastest horses trained for steeplechasing. The large field and the fast pace at which the race is run cause many falls and provide the spectators with an exciting and spectacular race.

From the American point of view the most important Grand National was that of 1938, which was won by Battleship, a horse owned by Mrs. Marion du Pont Scott of Montpelier, Va. Battleship's success was remarkable for several reasons. Standing merely 15 hands 2 in., he was one of the smallest horses ever to win the Grand National. He was the second American-bred horse to win, the first being Rubio in 1908, a horse bred at the Rancho del Paso in California and shipped to England as a yearling. Battleship was the first stallion to win since Grudon in 1901. The only other American-owned horses that have won the Grand National are Sergeant Murphy in 1923 owned by Stephen Sanford, Jack Horner in 1926 owned by C. Schwartz, and Kellsboro Jack in 1933 owned by Mrs. F. Ambrose Clark.

Steeplechasing in England and Ireland is under the control of the National Hunts Committee which assigns dates for the various meetings, draws up rules for conducting races, and regulates owners, trainers, and jockeys. The committee is a more important organization in the sport of racing in the British Isles than any similar organization is in America because in England almost the entire winter racing season is devoted to steeplechasing. From the end of the Taunton meeting in November to the Lincolnshire Handicap on April 1, except for a few minor meetings in Ireland, all racing is over jumps. It follows, therefore, that the steeplechaser gets a much larger share of the racing pound in England than of the racing dollar in the United States, where steeplechases are sandwiched in between flat races during the summer season. Because British steeplechase horses have such high earning powers, the horses competing in England are usually superior to those seen in America, and the numbers considerably greater. The caliber of the horses that appear in the paddock before the running of the Grand National is comparable with that of the well-bred horses that go to the post for the major handicaps on the flat in America. By the same token, more attention is paid to breeding steeplechasers in England and particularly in Ireland, a country which has produced the largest number of Grand National winners.

During a typical season there were fifty-four meetings run under National Hunt rules, of which nineteen were in Ireland. Next to the Liverpool meeting at Aintree, which includes the Grand National and is held in late March, the most important meeting is the National Hunt meeting held

earlier in March at Cheltenham. The principal feature is the Cheltenham Gold Cup at three miles and two furlongs. Although the Cheltenham Gold Cup is highly prized, the race is usually worth considerably less in purse value than the Grand National.

In addition to steeplechases held under National Hunt rules there are point-to-point meetings which are held under the jurisdiction of the Masters of Hounds Point-to-Point Committee. These are organized by the different hunt clubs of Great Britain and are held over courses within the territory hunted by each pack, usually over a piece of natural country with the fences altered, if necessary, to provide proper obstacles over which to race. Point-to-point meetings are also held by various army regiments, although since England abolished its cavalry units there have been fewer of these. In 1934 there were 186 point-to-point meetings held between February 17 and May 5, with from three to six races at each meeting. Point-to-point races are confined to horses which are the bona fide property of the persons in whose names they are entered and horses which are certified as genuine hunters by the Master of a hunt recognized by the Masters of Foxhounds Association and have been regularly and fairly hunted during the current hunting season. These meetings, which provide some of the finest amateur sport in the world and are very popular, serve also as a proving ground for young horses that might afterwards go on to compete in the major steeplechases under National Hunt rules.

Practically all the obstacles found in British steeplechase courses are brush fences, which are either natural hedges or artificial jumps made of spruce, fir, or some similar material. The lower part of a fence is thick and solid, but the upper part is thinner so that when a horse hits a fence he will usually be slowed up without falling. Another type of obstacle is the hurdle fences, a modification of the wooden sheep hurdles frequently seen in the English countryside. These are low in height—about three feet—and are designed for horses of considerable speed that are only moderate jumpers. On some of the courses in Ireland, such as Punchestown, there are also stone walls and banks, but these are exceptional. Almost all courses are provided with a water jump consisting of a small fence on the take-off side and a stretch of water eight feet or more in breadth on the other side.

Steeplechasing is also popular in the British dominions of New Zealand and Australia, in India, and in continental Europe—in Germany, Hungary, Belgium, and particularly in France and Italy, where most of the courses and conditions of racing are much like those in England.

INTERNATIONAL NEWS PHOTO

**Steeplechasing in the United States and Canada.** Steeplechasing was introduced in North America in 1838 with a hurdle race for horses hunted with the Montreal Hounds. The race was run under the patronage of the Governor General, the Earl of Durham, son of the first earl, who, as Lord Darlington and Master of the Raby pack, was perhaps the greatest M.F.H. of his day. In 1842 the Toronto garrison organized the first cross-country event in that section. The oldest steeplechase still in existence in North America is the Woodbine Steeplechase Handicap, a race of 2½ mi., held under the auspices of the Toronto Jockey Club and run for the first time in 1882, the winner being Mr. J. P. Dawes's Rose.

Steeplechasing was brought to the United States by Canadians in 1865. The first steeplechase was held at Paterson, N. J., on June 27 over twenty-seven jumps at a distance of three miles. The first three places were taken by Canadian horses, and in November of the same year another steeplechase was held at Lincoln, Mass., which the Canadians also won. Harry Worcester Smith in his chapter on steeplechasing in the United States in *Racing at Home and Abroad* states that the first steeplechasing at Newport, R. I., was not instituted until 1877. A column in the periodical *Turf, Field, and Farm* for Sept. 8, 1866, reveals that August 30 of that year marks the beginning of the cross-country sport at Newport.

The first steeplechase to be held at a major race track

was run at Jerome Park near New York City in October 1869 and was won by Col. McDaniels' Oysterman Jr. The Pimlico track at Baltimore, Md., followed with a race on Oct. 28, 1873, and thereafter, tracks like Rockaway and Saratoga, N. Y., Churchill Downs at Louisville, Ky., and the New Orleans Fair Grounds followed with events which established steeplechasing as a regular attraction.

Steeplechasing at the major tracks and at the Hunt Race Meetings in the United States is governed by the National Steeplechase and Hunt Association which formulates rules for the conduct of the sport and maintains an office in New York City. Some of the principal steeplechase events and the years in which they were inaugurated are:

| | |
|---|---|
| Battleship Steeplechase Handicap—Pimlico (Maryland) | 1938 |
| Beverwyck Steeplechase Handicap—Saratoga (New York) | 1897 |
| Brook Steeplechase Handicap—Belmont Park (New York) | 1905 |
| Charles L. Appleton Steeplechase—Belmont Park | 1922 |
| Chevy Chase Steeplechase Handicap—Laurel Park (Maryland) | 1911 |
| Corinthian Steeplechase Handicap—Belmont Park | 1902 |
| Glendale Steeplechase Handicap—Aqueduct (New York) | 1907 |
| Grand National Steeplechase—Belmont Park | 1899 |
| International Steeplechase Handicap—Belmont Park | 1895 |
| Indian River Steeplechase Handicap—Delaware Park (Delaware) | 1938 |
| Manly Steeplechase Handicap—Pimlico | 1916 |
| Meadow Brook Steeplechase Handicap—Belmont Park | 1916 |
| North American Steeplechase Handicap—Saratoga | 1904 |
| Saratoga Steeplechase Handicap—Saratoga | 1906 |
| Shillelah Steeplechase—Saratoga | 1902 |
| Temple Gwathmey Memorial Steeplechase—Belmont | 1924 |

Of these the Grand National Steeplechase at Belmont Park usually has the largest purse.

Total purse distribution at the major tracks in a typical year was $793,480, which, when added to the $58,545 distributed at the Hunt Race Meetings makes a total exceeding $850,000. This was still small, however, compared to the total purse distribution for flat racing at the major tracks in the same year—$48,497,544. During that year there were 244 races over jumps, 258 owners, and 426 horses. Principal meetings on the basis of purses distributed were Belmont Park, Aqueduct, Pimlico, and Saratoga in that order. By far the most successful breeder of steeplechasers was Mrs. Marion du Pont Scott, whose stallions Battleship and Annapolis, both sons of Man o' War, have been particularly consistent in siring jumpers.

In addition to the races held at major race tracks, there are a number of race meetings held annually under the auspices of some of the hunt clubs, which are also under the jurisdiction of the National Steeplechase and Hunt Committee. The courses are usually located in the districts hunted by the foxhound packs and are laid over the natural countryside, which is usually hilly and rolling in contrast to the courses at racetracks. An exception is the United Hunts meeting which is held at Belmont Park on two days each autumn under the auspices of the United Hunts Racing Association for the hunts in the New York area. Profits from this meeting are large, and since the United Hunts is a nonprofit organization a considerable proportion of the revenue is generously donated to increase purses at the smaller meetings in less populous areas. Of the $58,545 distributed by the fourteen hunt meetings in a typical year, $32,000 was donated to eleven meetings by United Hunts. Other important steeplechase meetings are the Rolling Rock Meeting at Ligonier, Pa., those at Middleburg and Montpelier in Virginia, and at Rose Tree near Philadelphia, Pa.

Steeplechase courses at the major race tracks are very much like those of the English tracks under jurisdiction of the National Hunts Committee, with both brush and hurdle courses. The hunt-meeting courses are usually regulation brush, but occasionally hurdle courses are utilized. Another type of course, found only in the United States, is the timber course modelled after the post-and-rail fences found in the American countryside. The races over brush at hunt meetings are from two to three miles, and over timber, from three to four miles.

The most famous of all races at the hunt meetings is the Maryland Hunt Cup held by the Green Spring Valley Hunt over a four-mile course in the Worthington Valley near Glyndon, Md. It includes twenty timber fences, some of them nearly five feet in height, and is considered by many experts, some of whom have ridden in the Liverpool Grand National, to be the most difficult course in the world. This meeting has several other unique features; namely, the Hunt Cup is the only race run at the meeting; it is for amateur riders only; no purse is involved; no admission is charged; and there is no grandstand. Steeplechase enthusiasts come from all over the country on the last Saturday in April every year, and as many as fifteen to twenty thousand people have gathered on the hillsides along the course to see the running. A number of horses that have won the Maryland have done well in the Liverpool Grand National, notably Billy Barton, who won in 1926 and later ran second in the National in spite of a shoe twisted during the running of the race. Although the Maryland Hunt Cup was inaugurated in 1894 and run annually thereafter, it was not until 1939 that the cup, which is retained by the owner of a horse that wins three times, was won outright when Blockade, by Man o' War, turned in his third consecutive triumph. The cup was retained again by Winton and his rider-owner Stuart Janney, Jr., who won in 1942 and came back to win again in 1946 and 1947. A. M.-S.

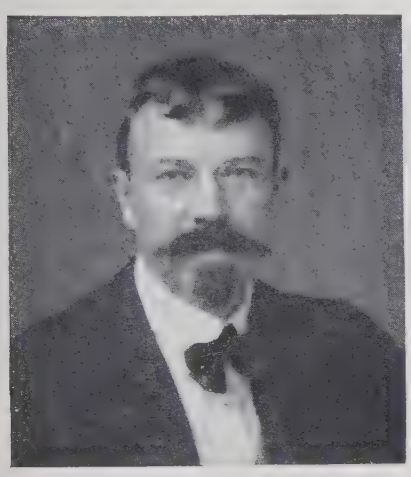
**STEFAN-BOLTZMANN LAW.** *See* HEAT AND THERMODYNAMICS (*Radiation*).

**STEFANSSON, VILHJALMUR** [stɛ'fɑnssɒn] (1879- ), Arctic explorer, was born of Icelandic parents in Arnes, Manitoba, Nov. 3, 1879. Educated at the University of Iowa and Harvard University, he went to Iceland in 1905 with a Harvard archaeological expedition. In 1906 he went on an ethnological expedition to the Eskimos at the mouth of the Mackenzie River and north Alaska, and between 1908 and 1912 he was a member of the longest Arctic expedition on record. Exploring the north of Canada and Alaska, this expedition studied the Eskimos and made investigations in the geographic sciences. From 1913 to 1918 he commanded the Canadian Arctic Expedition, which discovered the islands of Borden, Brock, Meighen, and Loughheed. He visited the Macdonnell Ranges of Central Australia in 1924, and from 1932 to 1945 he was adviser on northern operations for Pan American Airways. He has been Arctic consultant at Dartmouth College since 1947. In 1952 the Canadian Government named an Arctic island Stefansson Island in his honor. Author of many books, he also edited the U. S. Navy's *Encyclopedia Arctica*. S. Van V.

**STEFFENS, JOSEPH LINCOLN** [stɛ'fənz] (1866-1936), American journalist, was born in San Francisco, Apr. 6, 1866. Graduating from the University of California in 1889, he traveled in Europe and studied at the Universities of Berlin, Heidelberg, Leipzig, and Paris. Upon his return to the United States he took up newspaper work in New York City, serving as a reporter on the *Evening Post* from 1892 to 1897 and as city editor of the *Commercial Advertiser* from 1897 to 1902. He entered the magazine field in

1902 and for four years was managing editor of *McClure's Magazine.* In 1906 he and a number of associates purchased the *American Magazine,* but he resigned from that enterprise the following year and in 1910 joined the editorial board of *Everybody's Magazine.*

More important than Steffens' editorial work were the "muckraking" articles he wrote for *McClure's* and other crusading periodicals. The first decade of the century brought a flood of writing from such journalists as Ida Tarbell, Ray Stannard Baker, and David Graham Phillips, who, like Steffens, relentlessly exposed the political and economic corruption of American life and did much to build up the public sentiment necessary to achieve the reforms of the progressive movement. Steffens wrote two series of articles on corruption in city and state government, published in



JOSEPH LINCOLN STEFFENS

BROWN BROTHERS

book form as *The Shame of the Cities* and *The Struggle for Self-Government,* both of which created a sensation. Not content with revealing the facts, he strove to work out a theory of political corruption, finally concluding that it was an inevitable outgrowth of America's highly competitive economic system.

Steffens became increasingly interested in the labor problem and in 1911 intervened in the trial of two labor leaders, the McNamara brothers, who were accused of dynamiting the Los Angeles *Times* building. He was equally concerned with the comparative merits of reform and revolution as techniques of social progress. During the years 1914 to 1916 he made two trips to Mexico to observe the progress of the revolution in that country, and in 1917 to 1918 he made two trips to Russia, the second as a member of the Bullitt mission. He was favorably impressed by the Communist achievements. Subsequently he was present at the Paris Peace Conference in 1919 and made extensive lecture tours in the United States, speaking on labor questions and on his Mexican and Russian observations. During the 1920's Steffens felt that expanding American capitalism was pointing an evolutionary way to a future of abundance. With the coming of the depression of the 1930's, however, he became convinced that revolution was the only way to make "all reforms" possible and that "Communism has to come." His *Autobiography* (1931) became an American classic because of its significant picture of three decades of reform and revolution, its provocative ideas, and its vigorous style. During the last ten years of his life, from 1927 to 1936, he wrote weekly columns for various California journals, including *The Carmelite, Controversy,* and *Pacific Weekly;* these were collected in book form under the title *Lincoln Steffens Speaking.* He died at Carmel, Calif., Aug. 9, 1936. **STEIN, GERTRUDE** [stai'n] (1874-1946), American author, was born Feb. 3, 1874, in Allegheny, Pa. Her early life was spent in Europe and in California. She studied psychology with William James at Radcliffe, and later brain anatomy at Johns Hopkins University. In 1903, with a companion, Alice B. Toklas, she settled in France, where she remained until her death, except for a visit to the United States in 1934. In Paris she was the focus of the most advanced group of painters and writers, becoming the friend and patron of Picasso and Matisse, and exerting strong influence upon such American writers as Sherwood Anderson and Ernest Hemingway. The basis of her extraordinary influence lay in her experiments with language. Believing that "the business of art" is to live in "the complete actual present," she sought to achieve this effect in her writing by the use of partly repetitive statements, each representing some accretion of meaning, so that experience could be presented as it actually impresses itself upon consciousness. This aspect of her style was related to her experiments in automatic writing at Radcliffe. It represented a conscious abandonment of the rhythm and structure of literary prose in favor of the rhythm and structure of ordinary speech. Her writings in fiction included *Three Lives* (1909) and *Lucy Church Amiably* (1930). *Tender Buttons* (1914) was a volume of poetry in which she put into practice her theory that poetry is "really loving the name of anything," i.e., expressing vividly the actual qualities of things. Two autobiographical works were entitled *The Autobiography of Alice B. Toklas* (1933) and *Everybody's Autobiography* (1937). Her literary theories were set down in *How to Write* (1931) and *Lectures in America* (1935). In 1934 her opera *Four Saints in Three Acts* (musical score by Virgil Thomson) was successfully performed in America. She died at Neuilly on July 27, 1946. A posthumous novel, *Things as They Are,* was published in a limited edition in 1950. F. B. T.

**STEIN, BARON HEINRICH FRIEDRICH KARL VOM UND ZUM** [shtai'n] (1757-1831), German statesman, was born near the town of Nassau, Oct. 26, 1757. After studying law at the University of Göttingen, he entered the Prussian governmental service in 1780. He held several minor posts in the government before coming minister of mines in 1796. In this capacity he helped to develop the coal resources of the Ruhr Valley by improving the inland transportation facilities in Germany. He had the Ruhr canal system constructed and did much to improve road and river travel. Stein continued to hold office in the government but became widely known for his advocacy of changes and reforms in its administration. After Napoleon's crushing defeat of the Prussians at Jena in October 1806, a governmental change was in order and Stein was appointed prime minister in October 1807. He at once issued the Edict of Emancipation, which abolished serfdom in Prussia. He also did much to promote land reform and weaken the monopolistic hold that certain classes had on various professions and occupations. Stein reorganized the cabinet and instituted local self-government in the municipalities. His career as prime minister, auspicious as it was, was brief. One of his letters indirectly attacking Napoleon and professing hope for the liberation of Germany fell into the hands of the French. Threatened by Napoleon, Stein was forced to

resign and fled to Austria little more than fourteen months after he had taken office. In 1812 he went to Russia where he was an adviser to Tsar Alexander I during the Napoleonic invasion. After Napoleon's defeat, the Russians made Stein administrator of various recaptured territories. The erstwhile Prussian premier continued to work for the complete liberation of the German states and the establishment of a unified nation. His plans for a united Germany were defeated by Metternich and others at the Congress of Vienna in 1815, and Stein went into virtual retirement, during which he devoted himself to the study of history. Stein's practical nature and great energy were excellent complements to his social and political views. His study of the English enlightenment movement and the ideas of the French Physiocrats led him to believe firmly in humanitarian and governmental improvement. He was profoundly influenced by the first reforms of the French Revolution but deplored the violence with which these changes were effected. Stein died at Kappenberg, Westfalia, June 29, 1831. R. H. L.

**STEINBECK, JOHN ERNST** [stai'nbɛk] (1902- ), American novelist and short-story writer, was born at Salinas, Calif., on Feb. 27, 1902. He attended Stanford University at intervals between 1919 and 1925, worked at various jobs, and came to know intimately the farmers, migratory workers, and *paisanos* of whom he has chiefly written. Steinbeck's first novel, *Cup of Gold* (1929), based on the career of the pirate, Sir Henry Morgan, contained the romantic element that has ever since been discernible in his naturalism. Other manifestations of his romantic and sentimental tendencies can be seen in *To a God Unknown* (1933), concerned with pagan fertility-worship and the life force in nature; in *The Grapes of Wrath* (1939), his most popular and generally considered his best work, concerned with the migration and the later fate in California of Oklahoma sharecroppers and tenant-farmers who were driven from their land by the depression and the drought of the 1930's; and in his sympathy with strong, simple, natural men in *Of Mice and Men* (1937), *Cannery Row* (1946), *The Wayward Bus* (1947), and most of his other works.

These idealistic and emotional elements in Steinbeck's work connect him with the romantic naturalism of Emerson and Whitman, while scientific naturalism may be seen in comparatively pure form in the collections of short stories, *Pastures of Heaven* (1932), *Saint Katy the Virgin* (1936), *The Red Pony* (1937), and *The Long Valley* (1938), which contain some of the finest things the author has done. Steinbeck reached the high point of his fame as the chief proletarian novelist of the 1930's, a writer whose naturalistic objectivity of presentation was mingled with a great tenderness for the submerged and inarticulate masses, one of whose spokesmen he became. With the ebbing of the proletarian reform spirit of the 1930's, his work, although widely published and read, has seemed to many to lose certainty and direction. H. H. W.

**STEINBOK** or **STEENBOK** [stai'nbɒk; sti'nbɒk], a small antelope of the genus *Raphicerus* of southern and east central Africa. It is reddish or buff, white on the belly and legs, and measures about 22 in. high at the shoulders. Bucks and does have spikelike horns which are 3 to 5 in. long. Very speedy, they may crouch close to the ground until almost stepped upon before taking flight. Normally a resident of dry grassy plains, steinboks sometimes live in open forest. *See also* ANTELOPE. V. H. C.

**STEINDORFF, GEORG** [shtai'ndɔrf] (1861-1951), German Egyptologist, was born in Dessau, Germany, on Nov. 12, 1861. He studied from 1881 to 1884 at the universities of Berlin and Göttingen, and received his doctoral degree at Göttingen in 1884. He became the Assistant Curator of the Berlin Museum in 1885, and Professor of Egyptology at Leipzig in 1893. As a refugee from Nazism, he came to the United States in 1939, becoming a citizen in 1944. Steindorff's numerous contributions to Egyptology concern language, art, archaeology, history, religion, and travel, and they range from extremely technical investigations to highly successful popularizations. Steindorff's greatest scientific accomplishment is his *Koptische Grammatik* (1894), of which a third edition was completed; several generations of Coptic scholars have been brought up on this work. Steindorff's most widely read book is probably Baedeker's *Egypt and the Sudan,* of which he was editor and to which he contributed. His illustrated book on Egyptian art, *Die Kunst der Ägypter* (1928), is a good example of his ability to do sound and useful work for a wide public, while one of his most readable and interesting books, on a semipopular plane, is *When Egypt Ruled the East* (1942), written jointly with Professor Keith C. Seele. He later produced the *Catalogue of the Egyptian Sculpture in the Walters Art Gallery* (1946), a handsome and definitive publication of a rich collection that had hitherto been unknown to the scholarly world. Steindorff died in North Hollywood, Calif., on Aug. 28, 1951. C. H. Go.

**STEINMETZ, CHARLES PROTEUS** [stai'nmɛts; shtai'nmɛts] (1865-1923), German-American electrical engineer, was born a hunchback in Breslau, Germany, on Apr. 3, 1865. He studied at the University of Breslau and later attended the Polytechnic Institute in Zürich and wrote articles on astronomy. Forced to leave Germany because of a socialistic editorial that he wrote for a Breslau newspaper, he emigrated to America in 1889. He found employment as an electrical draftsman in Yonkers, N. Y., for Rudolf Eickemeyer, a hat manufacturer who was also an inventor and greatly interested in electricity. Steinmetz's genius soon became apparent. In 1892, at a meeting of the American Institute of Electrical Engineers, he gave a talk in which he elucidated the exact law of hysteresis. His findings showed that, within certain limits, the energy loss due to cyclic magnetization of a piece of iron or steel (hysteresis loss) is proportional to the 1.6th power of the maximum flux density attained in the iron. This knowledge made it possible to calculate in advance the losses in power resulting from this effect and placed the design of transformers and alternating-current motors and generators on a much firmer theoretical basis.

In 1893, Steinmetz became an engineer for the General Electric Co. in Schenectady, N. Y. He was a tireless worker, and as a result of his discoveries more than 200 patents were obtained by the General Electric Co., among them an aluminum lightning arrester to protect high-tension transmission lines, the magnetite arc lamp, and numerous improvements on generators and motors. He investigated the phenomenon of lightning, was interested in the wireless, and did much to establish alternating-current theory. In his later years Steinmetz helped to disprove the existence of the ether and had high praise for Einstein's relativity theory. He was elected president of the American Institute of Electrical Engineers in 1901. One year later he was appointed professor of electrical engineering at Union College, a position which he undertook in addition to his work with General Electric. He was the author of a number of books, including *Radi-*

*ation, Light and Illumination* (1909), *Engineering Mathematics* (1910), and works on electric discharges, relativity and space, and other subjects.

In his book *America and the New Epoch* (1916), Steinmetz expressed the view that private ownership would eventually yield to government ownership under private management. In 1922, he ran for state engineer on the Socialist ticket but was defeated. Steinmetz died in Schenectady on Oct. 26, 1923. I. B.

**STEINTHAL, HEYMANN** [shtai'ntɑl] (1823-1899), German linguist, was born May 16, 1823, at Gröbzig, in Anhalt. He studied philology and philosophy in Berlin from 1843 onward, became *Privatdozent* in that city in 1850, studied Chinese in Paris from 1852 to 1855, and in 1863 was nominated extraordinary professor at the University of Berlin. He died in Breslau on Mar. 14, 1899.

Steinthal combined some theories of Wilhelm von Humboldt and J. F. Herbart into a system of his own. Anthropology, he said, investigates the group of phenomena which lie between the physiological and psychological phenomena; ethnology investigates the spiritual life of nonhistorical peoples; and linguistics, the rules of parallel development within the various linguistic groups. Man, in contrast to animals, has produced culture and especially science. The latter originated out of a stage of higher morality and contributed to the development of a higher culture, especially to the concept of humanity. Progress, he felt, occurs slowly and cannot be accelerated artificially by revolution. The evolutionistic anthropological school of Adolf Bastian considered Steinthal's theories, as well as those of Moritz Lazarus and Theodor Waitz, as congenial; while the cultural-cyclical school of Wilhelm Schmidt rejected them.

Steinthal is, after Wilhelm von Humboldt, the most important representative of the Romantic school of linguistics. He stressed the role of the individual in the linguistic process and that of the nation as a whole in the shaping of its own particular language. The origin of language he saw in the progressive identification of sensations and impulses with the movements of the body and of the vocal chords. Devoting much effort to works of linguistic theory and philosophy, Steinthal followed the speculative idealistic trend of the Romantic period, and as respect for his ideas revived in the twentieth century, his work largely inspired the so-called neo-Romantic school of linguists, constituted mainly by E. Cassirer, W. Porzig, and Leo Weisgerber.

Among Steinthal's most important publications are *Die Sprachwissenschaft W. v. Humboldts und die hegelsche Philosophie* (1848), *Die Classification der Sprachen dargestellt als die Entwicklung der Sprachidee* (1850), *Der Ursprung der Sprache im Zusammenhange mit den letzten Fragen alles Wissens* (1851), *Die Entwicklung der Schrift* (1852), *Grammatik, Logik, Psychologie, ihre Prinzipien und ihr Verhältnis zu einander* (1855), *Charakteristik der hauptsächlichsten Typen des Sprachbaus* (1860), and *Geschichte der Sprachwissenschaft bei den Griechen und Römern* (1863). G. B. and P. H.

**STELE** or **STELA** [sti'li, sti'lə], a free-standing or, by extension, an engaged vertical tablet, which may be inscribed or decorated, and which is used for civic, religious, or commemorative purposes. In Egyptian tombs a vertical panel in the chamber wall, sometimes including a portrait of the deceased with hieroglyphic descriptions, is often called a "false door" because it resembles a domestic doorway; this stele may have represented an exit for passage of the spirit.

Greek gravestones, carved in low or medium relief, were often made in the form of a stele, with a figure representing the deceased or a group showing the deceased taking leave of family or friends. These were crowned with a pediment or anthemion. In Chinese tombs and temples, inscribed stelae mounted on the backs of turtles have a dragon figure across the top. L. R.

In the Western Hemisphere stelae are restricted to stone columns or monuments which were erected in prehistoric times in the Mayan area. For the most part they date from c. 300 to 1000 B.C. Some of these stelae are undecorated, although they may once have borne painted inscriptions or decorations. Those of greatest interest have hieroglyphic carvings in relief. These stelae glyphs have been translated, in part, and represent commemorative dates in the Mayan time-counting system, plus additional material of perhaps a historical or mythical nature. G. R. W.

**STELLAR MAGNITUDE.** Magnitude, in astronomy, indicates the brightness of a star or other celestial object. It does not refer to actual size. Early astronomers divided naked-eye stars into six magnitude classes. About twenty of the brightest stars were in magnitude 1, and the faintest stars visible under good conditions were in magnitude 6. Modern astronomers use the same system, somewhat revised. Fractional magnitudes are used; the very bright stars are assigned negative magnitudes. Telescopes can reach to magnitudes beyond 21. Thus, the fainter the star, the larger the positive value of magnitude.

The ratio of brightness between two stars differing by just one magnitude is the light ratio. This is approximately the number 2.512, the logarithm of which is 0.4. If the difference of two magnitudes is $m—n$, the light of two stars $l_n$ and $l_m$, and the ratio of apparent brightness $\frac{l_n}{l_m}$, the following relation holds:

$$\frac{l_n}{l_m} = (2.512)^{m-n},$$

which may be simplified to:

$$\log \frac{l_n}{l_m} = 0.4(m-n),$$

either form being useful in working magnitude problems. Thus, a difference of 3.0 magnitudes gives a light ratio of 15.85, and a difference of 5.0 magnitudes a light ratio of 100.0. Since there is a difference of 5 magnitudes between magnitudes 1 and 6, a star of magnitude 1.0 is 100 times as bright as one of magnitude 6.0.

There are several ways of using magnitude. The magnitude of an object as seen in the heavens is the apparent visual magnitude (apparent in contrast to absolute, and visual in contrast to photographic). The same system applied to photographic images on ordinary plates gives the photographic magnitude. The visual- and photo-magnitude scales agree for stars of class Ao and visual magnitude 6.0. But blue stars are brighter photographically than visually on ordinary photo plates, whereas yellow and red stars are dimmer. The difference between the photo and the visual magnitude is the star's color index:

color index = photo mag. — visual mag.

When photographs are made with color-sensitive film and filters giving color-correct results, the photo-visual magni-

tude is obtained. Apparent magnitudes of stars range from —1.58 (visual) for Sirius to + 21 or more (photo magnitude) for faint stars photographed with the largest telescopes. On this standard scale, the full moon is of magnitude —12.5, and the sun —26.7, while Venus may reach —4.4. Aldebaran's magnitude is +1.06, and that of Polaris is +2.12.

The apparent magnitude depends upon the object's own or intrinsic brightness and its distance, for, if the brightness itself is constant, the greater distance causes it to become fainter. Consequently, it is desirable to utilize the term absolute magnitude, which is the apparent magnitude of a star removed to a distance of 32.6 light years (10 parsecs), where the parallax is 0″.1. The range of absolute magnitude goes from —5 to +19.5 or more. The sun's absolute magnitude is +4.85. The absolute magnitude may be visual, photographic, or radiometric. The relation of the parallax, $p$, the observed apparent magnitude, $m$, and the absolute magnitude, $M$, is given by:

$$M = m + 5 + 5 \log p''$$

Inasmuch as many stars would far outshine the sun if at the same distance, it is important to know a star's intrinsic luminosity compared to the sun's; this is given by:

log of luminos. of star = 0.4 (4.85 — abs. mag. of star).

A radiometric magnitude is one determined with the thermocouple, a heat-measuring device sensitive to all radiations. The heat index of a star is obtained by the formula:

heat index = visual mag. — radio. mag.

**STELLARTON** [stɛ′lərtən], a town in Pictou Co., Nova Scotia, Canada, situated on the west bank of the East River of Pictou Harbour, about 75 mi. northeast of Halifax, on Provincial Highway 4. It is served by the Canadian National Railways. The town was incorporated in 1889. Coal mining, begun in 1798, is its chief occupation. Approximately 400,000 tons per year are produced. Pop. 1951, 5,575. D. F. P.

**STEM.** *See* Plant Anatomy.

**STENCILING.** *See* Printing and Graphic Arts (*Graphic Arts*).

**STENDHAL (MARIE HENRI BEYLE)** [stãⁿ′da′l, be′l] (1783-1842), French novelist and critic, was born on Jan. 23, 1783, at Grenoble, of an upper-middle-class family. As a child he made excellent progress in mathematics at the Ecole Centrale, in Grenoble. At the age of sixteen, he left Grenoble for Paris, intending to enter the Ecole Polytechnique and study mathematics. Once in Paris, however, he joined the army of Napoleon, attaining in 1801, in Italy, the rank of second lieutenant. While his military experience was brief, his impressions of Italy were responsible for his lifelong Italophilia. In 1805 he followed the actress Mélanie Guilbert to Marseille, where he became a clerk in a grocery store. His passion for Mélanie cooled and he returned to Paris in 1806. There, aided by his influential cousin, Pierre Daru, he was appointed a commissar in the Napoleonic armies. He served the emperor from 1806 to 1814, being one of the survivors of the retreat from Moscow. After the fall of Napoleon, he went to Milan, where, between 1814 and 1821, he lived a life devoted to love and political intrigue. He made his literary debut in 1814, publishing, under the pseudonym of Louis Alexandre César Bombet, *Vie de Haydn, de Mozart, et de Métastase,* in which he plagiarized an Italian writer. He continued with *Histoire de la peinture en Italie* (1817) and *Rome, Naples, et Florence* (1817). He was suspected as a *carbonaro* by the Austrian police in Milan and, fearing imprisonment, he returned to Paris, where he published in rapid succession: *De l'amour* (1822), a treatise on love, partly pseudo-scientific and partly anecdotal; *Vie de Rossini* (1824); and *Racine et Shakespeare* (1825), a plea for "romanticism" against "classicism." His first novel, *Armance* (1827), though weak, already suggests the interest of the author in the psychological self-analysis of his characters. After *Promenades dans Rome* (1829), there appeared, in 1830, the first of his two masterpieces, *Le Rouge et le Noir,* a novel in which the author reveals his extraordinary skill in the analytical and dynamic treatment of human behaviour.

STENDHAL
(MARIE HENRI BEYLE)

CULVER SERVICE

In 1830 Metternich refused to accept Stendhal as a French consul at Trieste, but in 1831 Stendhal became consul at Civitavecchia, a post he held to the end of his life. After his *Mémoires d'un touriste* (1838), Stendhal published *La Chartreuse de Parme* (1839), his second masterpiece, an absorbing novel in which character analysis, passionate affirmation of life, and intricate political intrigue blend in one of the finest works in fictional art. While on a visit to Paris Stendhal suffered an attack of apoplexy and died, Mar. 23, 1842.

With the gradual increase of Stendhal's reputation there began the posthumous publications of his unpublished manuscripts. Important among them are *Vie de Henri Brulard* (1890) and *Souvenirs d'égotisme* (1892), autobiographical sketches remarkable for their revelation of Stendhal's complex personality; *Lucien Leuwen* (1855), an unfinished novel, exposing some of the political evils existing during the reign of Louis Philippe; *Vie de Napoléon* (1876) and *Mémoires sur Napoléon* (1854); and *Chroniques Italiennes* (1929).

Stendhal's chief contribution to literature is his development of the analytical novel, in which his characters constantly indulge in pitiless psychological soliloquies in their passionate desire to understand their own actions and the reactions of the world around them. But his drily trenchant style, modeled after the *idéologues* of the eighteenth century and the "civil code," was repellent to his romantically effusive contemporaries. Only Balzac sensed his greatness. Stendhal's prophecy that he would be appreciated in 1880 or later came true. He is now considered one of the greatest French novelists. *See also* Rouge et le Noir, Le. M. Br.

**STENOGRAPHY.** *See* Shorthand.

**STENTOR,** a genus of Protozoa in the class Ciliata, so-called because of its trumpet-shaped body which is com-

pletely covered with cilia of uniform size. Species are found in fresh water as free-swimming or sessile (attached) organisms. Their bodies are highly contractile because of the well-developed internal fibrils (myonemes). They are comparatively large, 0.3 to 3 mm. long, and can be seen with the naked eye by a trained observer. Some are colorless whereas others are yellow, brown, rose, blue, or blue-green. The blue color is due to a pigment called stentorin. *Stentor coeruleus, S. polymorphus, S. mulleri,* and *S. amethystinus* have symbiotic algae, *Zoochlorella,* living within their bodies. R. F. N.

**STEPHANSSON, STEPHAN G.** [stɛ'fɑnssɒn] (1853-1927), Icelandic-Canadian poet-farmer, was born at Kirkjuhóll, Skagafjördur, Oct. 3, 1853, and came to the United States in 1873, finally settling in Alberta, Canada, in 1889. Stephansson had read the Icelandic sagas and the Eddas as a boy and had had no other schooling; yet he became one of the greatest poets of Iceland in his day and is considered by some the greatest poet in Canada. He made his debut in 1898. His collected poems, *Andvökur* ("Wakeful Nights"), were published in six volumes from 1909 to 1939; the title reveals his working hours. A realist, Stephansson was anticlerical and anticapitalistic, a great individualist, and an ardent lover of nature; visions of the natural beauty of America and Iceland rise from the pages of his poems. His poetry is intellectual, lyrical, and rich in Norse symbolism. He died Aug. 10, 1927, on his Alberta farm. S. E.

**STEPHEN, ST.** (died c. A.D. 35), the first Christian martyr, is known from the account of him in the sixth, seventh, and eighth chapters of the *Acts of the Apostles.* Of Jewish extraction but Greek culture, one of the first seven deacons chosen by the apostles, he was an especially gifted preacher and did "great wonders and signs among the people." Brought to trial before the Sanhedrin, Stephen so eloquently defended his preaching and so roundly condemned certain Jews that his enraged judges immediately cast him out of the city and stoned him. "Falling on his knees, he cried out with a loud voice, saying 'Lord, do not lay this sin against them.' " Stephen's feast day is December 26. W. C.

**STEPHEN I, ST.** (c.200-257), pope, was a Roman. His pontificate (254-257), while not disturbed by civil persecution, was a time of great internal strife. In the struggle about the rebaptism of those baptized by heretics, Stephen, acting explicitly as successor of St. Peter, ordered that in accord with the tradition of the Roman Church such persons should not be rebaptized, baptism by heretics being held valid. On this issue he broke with the North Africans under Cyprian as well as with some churches of Asia Minor. Although he died at the beginning of the Valerian persecution, Stephen was not a martyr. E. A. R.

**STEPHEN III** (c.690-757), pope, succeeded Stephen II in 752. Inasmuch as Stephen II died without being consecrated, a few days after his election to the papacy, some writers omit him from the list of popes and give the title Stephen II to his successor.

During the pontificate of Stephen III the Papal States were founded, an event of importance in world history. Stephen was forced by his difficulties with the Lombards to cross the Alps—the first time a pope made the journey—to ask aid of Pepin the Short, Frankish king by the grace of Pope St. Zachary. In 754 Pepin promised to make the pope a temporal ruler, and, in 756, after a successful military expedition against the Lombards, Pepin presented to Stephen the states he had won from the Lombards, laying the keys to their cities on the tomb of St. Peter. Stephen died April 26, 757. E. A. R.

**STEPHEN** (c. 1097-1154), King of England, third son of Stephen Henry, Count of Blois and Chartres, and his wife, Adela, daughter of William I, was born in Normandy about 1097. He was brought up and educated by his uncle, Henry I of England. After the death of Henry's son, William, in 1120, Stephen was regarded as the logical heir to the throne, but in 1125 he swore, with the lay barons, to acknowledge Henry's daughter, the widowed Empress Matilda, as heir of England and Normandy. However, on Henry's death in 1135, Stephen claimed the throne and, sailing for England, was chosen king by the Londoners and crowned at Westminster, Dec. 25, 1135. In 1136 he bought off the king of the Scots, David I, who had invaded Northumberland, issued two charters of liberties, and crushed a rebellion of the barons. The following year he made a truce in Normandy with Matilda's second husband, Geoffrey of Anjou, and repelled a second Scottish invasion.

In 1138 the barons, alienated by Stephen's extravagance and use of foreign mercenaries, rose in revolt, and in the same year the clergy turned against the king after he had arrested and dealt harshly with the bishops of Salisbury, Lincoln, and Ely. After permitting Matilda to join her half-brother, Robert, Earl of Gloucester, at Bristol in 1139, Stephen lost the western shires to the empress. At the Battle of Lincoln in 1141 he was defeated and captured by Gloucester, and for six months Matilda reigned as sovereign. Her harsh rule, however, soon turned the tide against her, and in November 1141 Stephen was released and again declared king. Until 1148, when Matilda withdrew from England, Stephen was engaged in a constant struggle against the empress and her supporters, and was unable to prevent the conquest of Normandy by Geoffrey of Anjou in 1141. He also had again incurred the displeasure of the Church and in 1152 was unable to secure papal sanction for the coronation of his son Eustace as his successor. When Matilda's son Henry, Duke of Normandy (afterwards Henry II), invaded England in 1153, Stephen, disheartened by the long struggle and the death of his wife, Matilda of Boulogne, and their son Eustace, signed a treaty at Wallingford (1153) acknowledging Henry as heir to the throne. He died at Dover, Oct. 25, 1154. C. W. D.

**STEPHEN** (Hung. István), the name of five kings of Hungary, the two most important of whom were as follows.

**Stephen I** (c. 975-1038), known as Saint Stephen, first king of the Árpád Dynasty, was the son of Géza, Duke of Hungary. He married Gisela of Bavaria in 996 and the following year, on the death of his father, succeeded to the ducal authority. A convert to Christianity, Stephen defeated a pagan rebellion under Kopány in 998 and received papal recognition in 1000. In 1001 he was crowned apostolic king with a crown sent by Pope Sylvester II. Stephen's reign was marked by a series of struggles against the heathen nobles and by his attempts to impose Christian reforms on the Magyars. He founded several bishoprics and monasteries and divided his kingdom into forty-five counties, becoming the first organizer of political life in Hungary. In 1030 Stephen successfully repulsed an invasion by the emperor Conrad II. He died in 1038 and was canonized in 1038.

**Stephen V** (1239-1272) was the eldest son of Béla IV. As crown prince, he forced his father to divide the kingdom and to share the royal authority with him. Invading Bulgaria in 1268, Stephen established himself as king of the

Bulgarians. He succeeded his father to the throne of Hungary in 1270, and in 1271 repelled an invasion of the kingdom by Ottokar II of Bohemia. He died suddenly in 1272.
C. W. D.

**STEPHEN, SIR LESLIE** (1832-1904), English biographer, philosopher, and man of letters, was born in London, Nov. 28, 1832. A precocious child, he was educated at home and at Eton, and attended King's College, London, and Trinity Hall, Cambridge. After being ordained in order to hold academic positions, he rejected the historical evidences of Christianity in 1862 and in 1870 relinquished orders, justifying his course in *An Agnostic's Apology* (1876). As a professional writer he contributed to many periodicals, wrote numerous lives for the "English Men of Letters" series, edited the *Cornhill Magazine* (1871-1882), and crowned his biographical activities by editing the *Dictionary of National Biography* (1882-1891). His essays were collected as three series of *Hours in a Library* (1874, 1876, 1879) and as two series of *Studies of a Biographer* (1899, 1902). He did distinguished work in historical economics and political philosophy in *A History of English Thought in the Eighteenth Century* (1876) and *The English Utilitarians* (1900). His personal attitudes are expressed in *A Science of Ethics* (1882). Virginia Woolf, the novelist, was his younger daughter. Stephen died in London, Feb. 22, 1904.
W. C. He.

**STEPHEN NEMANYA** [nɛ'mɑnyɑ] (*Serb.* Stevan Nemanja), the name of a series of rulers of Serbia, the Nemanyan Dynasty, which extended from 1168 to 1371. The house was founded by Stephen Nemanya (1114-1200), the Serbian grand zupan (chief), who ruled from 1168 to 1196 and was the first to bring a measure of unity to the Serbs as a means of resisting Turkish territorial encroachments. In 1196 he resigned his rule and joined his oldest son (St. Saba) at the monastery he had founded on Mt. Athos, where he died four years later. He was succeeded by another son, who was crowned by papal authority in 1217 as Stephen Nemanya I (d. c. 1228).

The most famous of the line was Stephen Urosh IV, Nemanya IX, known as Stephen Dushan or Dušan (c. 1308-1355). In 1331 he rebelled against and imprisoned his father, Stephen Urosh III, Nemanya VIII (d. 1334), who is accounted a saint by the Serbian church although he has never been canonized. A great warrior and statesman, Stephen Dushan attempted to form a Serbo-Greek empire on the Balkan Peninsula in order to prevent Turkish invasion of the then disorganized Byzantine Empire. Toward this end he took Albania, Epirus, Thessaly, and all of Macedonia but Salonika. Crowned king of Serbia in 1335, in 1345 he was proclaimed emperor of the Serbs, Greeks, Bulgars, and Albanians. Between 1349 and 1354 he had the parliament draw up the Code of Dushan, which was used as the foundation of later Serbian legislation. In 1350 he took Bosnia. Preparing to lay siege to Constantinople, he died suddenly under suspicious circumstances on Dec. 20, 1355.

Stephen Urosh V, Nemanya X (1336-1371), was the son of Stephen Dushan and the last of the line. After Dushan's death, the provincial rulers revolted and the Turks took advantage of this disorganization to enter his lands. His army was defeated by the Turks on the Maritsa River, and two months later, in November 1371, Stephen died.
R. T.

**STEPHENS, JAMES** (1882-1950), Irish author and a leading member of the Irish Academy of Letters, was born in Dublin, Feb. 2, 1882. He is described by Frank Swinnerton in *The Georgian Scene* as small and slight with "the face of one who dwells . . . in a world mocked and twisted by fairies." Emerging from a poverty-hounded youth, he became a contributor to *Sinn Fein* and a protégé of George Russell several years before publishing his first book, *Insurrections* (1909), a volume of verse. He was co-founder (1911) of *The Irish Review,* wherein appeared his first novel, a reflection of Dublin tenement life issued in book form in 1912 as *The Charwoman's Daughter* (American title, *Mary, Mary*). He won the 1912 Polignac Prize with *The Crock of Gold,* a prose fantasy, and the Tailltean Gold Medal with *Deirdre* (1923), a romance. After a sojourn in Paris from about 1912 to 1916, he returned to Dublin to serve as registrar of the National Gallery of Ireland until 1925, when he began a series of annual lecture tours in America. Subsequently, though a vigorous Nationalist, he lived largely in suburban

*JAMES STEPHENS*

BROWN BROTHERS

London, where he had married in 1917, maintaining his fabulous reputation as a conversationalist and occasionally doing radio broadcasts.

At times a derivative versifier, though subtle as a critic and suggestive of affinities with Synge and Gissing, Stephens perhaps achieved his greatest originality and poetic effectiveness in the following works: *The Crock of Gold; Here Are Ladies* (1913), a compound of story, essay, and verse; *The Demi-Gods* (1914), a wildly beautiful tale of tinkers and of angels masquerading as mortals; *Etched in Moonlight* (1928), a collection of short stories; and certain incomparable lyrics, most of which can be found in *Collected Poems* (1926) and *Kings and the Moon* (1938). However, Stephens' reshaping of Fenian tradition in *Irish Fairy Tales* (1920) and of matter from the ancient Ulster story-cycle in *Deirdre* and *In the Land of Youth* (1924), a volume containing two tales, each of novelette length, put to use a pace, a naturalness, and a magical quality rarely found in English prose. Perhaps the secret of Stephens' art lies partly in his early recognition of writing as "a way of being"; his caprice, which often is less real than apparent; his humor, frequently ironic, but nourished by an essentially religious concept of joy; and his vitality, to which a remark in *The Demi-Gods* gives the key: "There was no old age in that man's mind." Stephens died in London on Dec. 26, 1950.
G. B. S.

**STEPHENS, JOHN** (fl. c.1615), English satirist and a member of a politically prominent Gloucester family. From 1611 forward he practiced law in London without evidently achieving unusual success. His contribution to literature is his *Satyrical Essayes, Characters, and Others* (1615), a volume

of short character sketches containing historically interesting details, especially in portraits with a background of law. He joined with Joseph Hall, Sir Thomas Overbury, and John Earle in effecting the nationalization of the Theophrastan character in England, but in contrast with most character-writers, he showed an ability to discern traits which set individuals apart from types. *See also* CHARACTER. M. L. MacL.

**STEPHENSON, GEORGE** (1781-1848), English inventor and pioneer in railroading, was born in Wylam, near Newcastle, on June 9, 1781. In 1795 he became assistant fireman to his father, a miner at Dewley colliery, and in his spare time he repaired watches and clocks, his mechanical ability earning for him the position of enginewright at the Killingworth mine in 1812. Stephenson had made a study of the steam engine of James Watt, and in 1813 he received

GEORGE STEPHENSON

FROM AN ENGRAVING BY W. G. JACKMAN

COURTESY OF THE NEW YORK PUBLIC LIBRARY

financial backing to construct a steam locomotive. On July 25, 1814, this locomotive, named the *Blücher,* made a successful trial run. In 1815 Stephenson patented the steam blast, a device to increase the draft in the boiler, and invented a safety lamp for miners at about the same time that Sir Humphrey Davy invented his safety lamp; for years there was controversy as to who had prior claim to this invention.

Stephenson supervised the construction of an 8-mi. railway for the Hetton colliery, begun in 1819 and completed in 1822, and in 1823 he founded a locomotive factory in Newcastle. In 1825, for the Stockton and Darlington Railway, Stephenson built a locomotive weighing eight tons and having a top speed of 16 m.p.h. He next served as construction engineer to the Liverpool and Manchester Railway, overcoming formidable natural obstacles in building the roadbed. The sponsors of this railway declared an open competition to choose a locomotive, with a prize of £500, which Stephenson won at Rainfall in 1829 with his engine the *Rocket,* covering 12 mi. in 53 minutes. The railway was opened one year later. Stephenson was consulted in the planning of numerous railways in the years that followed and served as chief engineer for the Manchester to Leeds, Birmingham to Derby, Derby to Leeds, Normanton to York, Sheffield to Rotherham, and other railways. He also helped build railways in Belgium and Spain. He recognized the necessity for tunnels and embankments to avoid steep grades and advocated the use of malleable iron instead of cast-iron rails. He founded the Institute of Mechanical Engineers and became its president in 1847. Stephenson died on Aug. 12, 1848, at Tapton House, near Chesterfield. I. B.

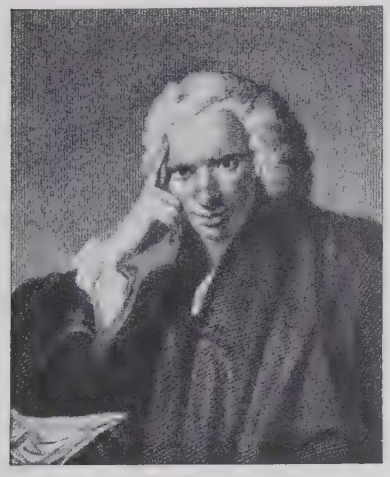
**STERLING,** a city and the county seat of Logan Co., Colo., on the South Platte River, 115 mi. northeast of Denver, at an altitude of 3,947 ft. above sea level. Sterling is an important railroad junction and the main distributing point for a wide agricultural, dairying, and stock-raising district. Manufacturing centers around the large beet-sugar refinery of the Great Western Sugar Company. The valley of the South Platte at this point was first settled in 1872, and the town site was platted in 1881. Incorporated in 1883, the growth of the town as a trading center was rapid, largely owing to the exceptional productivity of the surrounding area. Pop. 1950, 7,534. C. W. D.

**STERLING,** a city in Whiteside Co., in northwestern Illinois, situated on Rock River, 110 mi. west of Chicago. It is served by the Chicago and North Western and the Chicago, Burlington & Quincy railroads. Builders' hardware and steel products constitute the chief manufactures. The surrounding region is agricultural. To the northeast is White Pines Forest State Park. Sterling was incorporated in 1857. Pop. 1950, 12,817.

**STERN, OTTO** [shtɛ′rn; stɜ′rn] (1888- ), German-American physicist, was born in Sohrau, Germany, Feb. 17, 1888. He was educated in Germany, obtaining his Ph.D. degree at Breslau in 1912. He was *privatdozent* at the Technische Hochschule, Zürich, in 1913 and 1914; and at Frankfurt from 1914 to 1921. In 1921 and 1922 he was professor of physics at Rostock, and from 1923 to 1933 he was professor at Hamburg. He came to the United States in 1933 as research professor of physics at the Carnegie Institute of Technology. Stern is most noted for his highly significant measurements of the magnetic properties of individual atoms. In 1921, with Walter Gerlach, he performed the classical experiment on atomic magnetic moments which became one of the experimental foundations of modern quantum theory. In 1933 he refined his experimental technique so that he was able to measure the magnetic moment of atomic nuclei. He was awarded the 1943 Nobel Prize in physics. L. N. R.

**STERNE, LAURENCE** (1713-1768), English novelist, was born at Clonmel, Ireland, Nov. 24, 1713. His father, an improvident army ensign, after dragging his family through various barracks in Ireland, left ten-year-old Laurence at school in Yorkshire, near influential relatives who in 1733 helped him enter Jesus College, Cambridge. The Church was an inevitable career for the great-grandson of an archbishop and nephew of an archdeacon. Ordained priest in 1738, Sterne shortly became vicar of Sutton and prebendary of York Cathedral. In 1741 he married Elizabeth Lumley. Her income increased his security, and their daughter Lydia became his chief joy, but his wife's emotional instability and his own indiscreet flirtations severely strained his marriage. Always frail, he was frequently prostrated by hemorrhages, which began when he was at Cambridge. He quarreled simultaneously with his mother, who pestered him insatiably for money, and with his uncle, the archdeacon. In 1758 his wife became temporarily insane.

During these troubled years Sterne's solace was a group of eccentric companions, the "Demoniacs." Their leader was Hall-Stevenson, and the scene of their mild escapades was his Skelton Castle, with its library of curious and indecent lore. There, especially from Burton and Rabelais, Sterne acquired much of the odd learning which crams his books. Fortunately all his models were not esoteric; they included Montaigne, Shakespeare, Cervantes, Locke, and Swift. Sterne's way of life, his pamphleteering, and his dramatic and unorthodox sermons had already molded his



*LAURENCE STERNE*

COURTESY OF THE NEW YORK PUBLIC LIBRARY

style and brought him a local reputation before he journeyed to London in December 1759, with the first two volumes of *Tristram Shandy*.

The wit, humor, and audacity of this work and of Sterne's conversation captivated London. Dr. Johnson dismissed him as a fad; Horace Walpole denounced him; Bishop Warburton, after befriending him, turned against him; Garrick remained staunch. Within a year Sterne published four more volumes of his novel, then spent 1762-1764 with his family in southern France, vainly seeking health. A year in England, two more volumes of *Tristram Shandy,* and he was back in France and wandering through Italy, still racked with coughing, still determinedly cheerful. His wife and daughter, who had refused to return to England since first landing in France, again let him go home alone. In 1767 he finished the ninth and last volume of *Tristram Shandy*. Now fast dying of consumption, he became sentimentally infatuated with Mrs. Draper (the Eliza of the *Journal* published after his death); but she rejoined her husband in India, and soon thereafter Sterne permanently but amicably separated from his wife. Early in 1768 he hurried to London to publish *A Sentimental Journey,* and there, assured of its success but lonely among friends, he died on March 18.

**Personality and Literary Style.** Sterne's life both helps and hinders understanding his work, most of which is semi-autobiographical. He draws on his travels in France for *A Sentimental Journey,* and is always breaking into *Tristram Shandy* with reminiscence and interjection; in fact, his own personality gives unity to a deceptively chaotic book. But Sterne's self-portrait as Yorick is selective, what he wanted to be and to be thought—sometimes better, often worse than he was. His mercurial temperament, his devil-may-care recklessness he deliberately accentuates; his illness and share of genuine tragedy he ignores or turns into comedy. He once wrote, "The world has imagined, because I wrote *Tristram Shandy,* that I was myself more Shandean than I really ever was." By "Shandean" he meant an attitude of constant attack on melancholy, and on religious and moral austerity; enthusiastic support of joy, sentiment, and the natural goodness of man. Sterne always appeals from the head to the heart, and not all these appeals are mawkish. Sometimes he smirks lewdly; but basically he pleads for tolerance of frailty, and his best comedy is of the highest order, since he understands human nature. Not only is irony tempered with affection; his sentimentality is often ironic self-satire. His wit lies as much in precision of phrase as in ambiguity and innuendo. While his tricks, anticlimaxes, and digressions are frequently tiresome, he is a master of surprise and drama; his writing is so sharply visualized that events described seem to happen in reality.

Of his two masterpieces, *A Sentimental Journey* is slighter, more carefully contrived. Its prose ranks with the most felicitous prose in English. Sterne travels in the character of Yorick, not to see places but to meet people. He delights in subtle distinctions and revealing peculiarities, sketching brilliantly in few strokes; his only full-length portrait is that of his servant, La Fleur. But Sterne's virtuosity requires the larger, less-finished canvas of *Tristram Shandy,* crowded with minor figures such as La Fever, Widow Wadman, Doctor Slop, and Corporal Trim, in their way as entertaining as Walter Shandy and Uncle Toby.

Though his caricature and pathetic comedy influenced such novelists as Dickens, Sterne is inimitable. He seemed outside the main tradition of the novel until James Joyce and others developed the stream-of-consciousness technique, which has changed our perspective and made us more aware of Sterne's brilliant and subtle, if seldom profound, psychological penetration. *See also* SENTIMENTAL JOURNEY, A; TRISTRAM SHANDY.

W. B. C. W.

**STERNE, MAURICE** [stɜ′rn] (1878- ), Russian-American painter, was born July 13, 1878, in Russia. Removing to the United States in 1889, he studied at Cooper Union in 1892 and at the National Academy of Design from 1894 to 1899. By 1903 he was an instructor in etching at the National Academy, and by 1904, he had qualified for its traveling scholarship in Europe. Remaining four years abroad, Sterne toured many art centers and started work as a sculptor. He visited Egypt in 1911 and Burma and Java in 1912, returning to the United States in 1915. During this period, between travels, he held many exhibitions. In 1929 his *Monument to Early Settlers* was unveiled at Worcester, Mass., and four years later he had a one-man show at New York's Museum of Modern Art. In the 1930's Sterne again lived in Europe and later did murals for the United States Department of Justice. These prompted Royal Cortissoz, the critic, to say that Sterne "mixed brain-stuff with his colors," while Thomas Craven has said, ". . . his approach to art is that of one who has the sympathetic and sensitive but penetrating understanding of a great humanist."

J. Me.

**STESICHORUS** [stəsɪ′kɔrəs] (c. 632-553 B.C.), Greek lyric poet, was born at Locri in southern Italy. Living at a time slightly later than Alcman's, he was approximately a contemporary of Alcaeus and Sappho. Although his career is chiefly associated with Himera in Sicily, he probably also spent some years in the Peloponnesos. He is said to have reached his eightieth year.

His real name was Tisias; the nickname Stesichorus (Chorus Marshaler) is derived from his poetic activity. The combined Dorian and Ionian heritage of his adopted home, Himera, enabled him to emancipate Dorian choral song and

make it Panhellenic. This important writer's works, later edited in twenty-six books, have been so poorly preserved that our loss must be regarded as staggering. His poems were chiefly large-scale festival hymns, narrative in character and drawing freely on epic poetry for material. They include *Funeral Games for Pelias, Oresteia, Helen,* and the *Sack of Ilium.* Stesichorus remodeled many of the myths upon which he drew, and gave them a form which influenced Attic tragedy and pictorial art of all kinds. His use of the Daphnis story and his *Rhadine* and *Calyce* establish him as the remote ancestor of the pastoral and the romantic novel. Quintilian justly called him a lyric Homer who bore the weight of epic on his lyre. C. M. D.

**STETHOSCOPE.** *See* LAËNNEC, RENÉ THÉOPHILE HYACINTHE.

**STETTIN.** *See* SZCZECIN OR STETTIN.

**STETTINIUS, EDWARD REILLY, JR.** (1900-1949), American financier and statesman, was born in Chicago, Ill., Oct. 22, 1900. He was educated at Pomfret School and at the University of Virginia. He left college in 1924 to join the General Motors Corporation, of which he was made a vice-president in 1931. He joined the United States Steel Corporation in 1934, becoming chairman of the board in 1938. In 1939 Stettinius was made head of the national War Resources Board. In 1940 he resigned from private business and served for a year as an adviser to the Council of National Defense, then as lend-lease administrator. In 1943 he was appointed Under-Secretary of State and a year later succeeded Cordell Hull as Secretary. As Secretary, he attended the Yalta Conference in February, and headed the American delegation to the San Francisco Conference of the United Nations in April 1945. He resigned as Secretary in June of that year but continued for another year as permanent delegate to the United Nations. He died at Greenwich, Conn., Oct. 31, 1949. C. W. D.

**STEUBEN, BARON FRIEDRICH WILHELM LUDOLF GERHARD AUGUSTIN VON** [styu′bən; shtɔi′bən] (1730-1794), German-American general, was born Nov. 15, 1730, in Magdeburg, Prussia. Tutoring by his father, a Prussian captain, and intermittent schooling at Neisse and under the Jesuits at Breslau prepared Steuben for the career he began as a Prussian lance corporal in 1746. Although further trained in the military classes of Frederick the Great during the Seven Years' War (1756-1763), he was only a captain when discharged in 1763. After leaving Prussia, he served as grand marshal at the court of Prince Hohenzollern-Hechingen, where he was knighted in 1769. However, subsequent financial difficulties, visits to Paris, and meetings with Benjamin Franklin inspired him to volunteer for American service with remuneration contingent upon the winning of independence. Von Steuben sailed for America in 1777, presented himself to Congress, and in February 1778 reported to General George Washington at Valley Forge. When Congress appointed him inspector general that year, with a major general's commission dated May 5, he had already inaugurated unified drill regulations for the Continental Army and expedited its reorganization. At Monmouth and throughout the 1779 and 1780 campaigns, he was Washington's tactical adviser. At West Point he systematized Howe's fortification procedures and light infantry operations. He also commanded the Yorktown forces that received General Charles Cornwallis' first offer of capitulation and, at the war's end, assisted in demobilization.

Von Steuben was discharged from the Army in 1784 and became a naturalized American citizen. Membership on the first Board of Regents of the University of the State of New York, presidency of the Society of the Cincinnati, a gold-hilted sword, special thanks from Congress, and rich but unsalable land grants were among the honors he received. However, not until 1790 did Congress grant him an annual pension to recompense him for brilliantly transforming Washington's ragged armies into effective, well-disciplined troops. He died at Steuben, Oneida Co., N. Y., on Nov. 28, 1794. M. C. C.

**STEUBENVILLE** [styu′bənvɪl], a city in eastern Ohio, the county seat of Jefferson Co., situated on the Ohio River, on the Ohio-West Virginia boundary, about 50 mi. southeast of Canton and 23 mi. north of Wheeling, W. Va. Steubenville is built on a plain surrounded by high hills with rich oil, gas, and clay deposits. Shaft and strip mining of these minerals is a leading activity in the region. The city was the site of Fort Steuben, built during the Revolutionary War and named for Baron Friedrich Wilhelm von Steuben. The community was settled in 1797 and incorporated in 1854. During the Civil War it was an important post on the Underground Railroad. Edwin M. Stanton, Secretary of War under Lincoln, made his home in Steubenville, which developed early in the nineteenth century as an industrial center. The community was one of the first to employ steam for manufacturing purposes. Transportation for the city is furnished by river craft and the Pennsylvania and Wheeling and Lake Erie railroads. Steel production is the predominant industry. Pottery, nitrous products, paper, and wood products are other manufactures. Pop. 1950, 35,872.

**STEVENS, JOHN** (1749-1838), American engineer, was born in New York City in 1749. He studied law and was admitted to the New York bar in 1771. From 1777 to 1782 he was treasurer of New Jersey. However, he is best known for his improvements of the motive power and machinery of steamboats. In order to protect his inventions, he presented a petition which was used as the basis of the first United States patent law in 1790. He applied for some of the earliest patents—for a multitubular boiler and for a method of screw propulsion for steamboats. In 1808 Stevens built the engine for the *Phoenix,* which, as the first ocean-going steamboat, he sailed from New York to Philadelphia. Proposing bridges across the Hudson and East rivers and a tunnel under the Hudson, he was ridiculed as a dreamer. At the request of a joint army and navy board, he wrote with his son Edwin Augustus Stevens (1795-1868) a report on armed steamboats as a means of coastal defense.

Also interested in railroads, Stevens, on Feb. 6, 1815, received the first railroad charter in the United States for a line across New Jersey between the Delaware and Raritan rivers, although it was not until 1830 that he formed the Camden and Amboy Railroad and Transportation Company and not until 1832 that the first train was run. He also bought much land in Hoboken, around the site of the ferry landing, and was active in the development of the city. Stevens died in Hoboken on Mar. 6, 1838. S. M. M.

**STEVENS, ROBERT LIVINGSTON** (1787-1856), American engineer, was born in New York City on Oct. 18, 1787, the second son of John Stevens. He was trained by his father in mathematics and mechanics, proved an exceptionally able student, and at seventeen helped his father build the first twin-screw steamboat. In 1841, Robert Stevens and

his brother, Edwin Augustus Stevens (1795-1868), designed for the United States Government the so-called *Stevens Battery,* an armor-plated vessel capable of withstanding the 64-lb. shot, the heaviest then in use.

The two brothers managed their father's Camden and Amboy Railroad and Transportation Company, which later became part of the Pennsylvania Railroad. In 1830 Robert Stevens went to England to procure equipment for their railroad, and, dissatisfied with the size of the English rails, designed the rail which has since become the universal standard. He also invented the hooked spike that holds the rails in place and made improvements in the current roadbed. His engine, the *John Bull,* made its first short trip on Nov. 12, 1831, although the line was not in operation until 1832. Stevens died on Apr. 20, 1856. *See also* STEVENS INSTITUTE OF TECHNOLOGY. S. M. M.

**STEVENS, THADDEUS** (1792-1868), American lawyer and congressman, was born at Danville, Vt., Apr. 4, 1792. He was graduated from Dartmouth College in 1814, and while teaching in a school at York, Pa., began to read law. He practiced at Gettysburg, Pa., for fifteen years, and became a prominent lawyer. His intense hatred of slavery led him to defend many runaway slaves without charge.

As a leader of the Anti-Masonic Party, Stevens was elected to the Pennsylvania House of Representatives in 1833, and served three terms (1833-1835, 1838-1839, 1841-1842). He won fame for his efforts to extend the free-school system over the entire state. He retired temporarily from politics in 1842 and returned to the practice of law at Lancaster, Pa., but was elected to Congress on the Whig ticket in 1848. He was vigorous in his opposition to the Fugitive Slave Law of 1850. His term ended in 1853, but he was re-elected in 1858 and, as one of the leaders of the Republican radicals, was known for his fierce speeches against slavery and was in favor of protective tariffs. He was prominent in organizing the Republican Party in Pennsylvania.

In 1861, Stevens became chairman of the House Ways and Means Committee, and though he gave President Abraham Lincoln full support in carrying out necessary financial measures during the Civil War, his views on the conduct of the war did not coincide with the President's. He was harsh and vindictive toward the South, and in 1864 spoke of exterminating the "rebels" and recolonizing the South. During Reconstruction, Stevens wanted the South to be under a severe military government, and he has often been held responsible for accentuating reconstruction problems.

Stevens was a leader in the Congressional struggle with President Andrew Johnson, and was chairman of the group that drafted the impeachment, although he was not active in the trial because of ill health. He died in Washington, D. C., on Aug. 11, 1868, after having requested burial in a cemetery in Lancaster, Pa. because it was open to Negroes. R. F.

**STEVENS INSTITUTE OF TECHNOLOGY,** an accredited, nondenominational, privately controlled technological school for men. The main campus covers 30 acres in Hoboken, N. J., and the summer engineering camp occupies a 345-acre tract at Johnsonburg, N. J. The institute, founded under a bequest left by Edwin A. Stevens in 1868, was incorporated in 1870, and first instruction was given the following year. Graduate courses were introduced in 1930, and the Graduate School was formally organized in 1938.

The only degrees offered are the M.E. and the M.S. All freshmen are required to attend the six-week summer camp. In the library are the collection of the Stevens family papers and the Taylor collection on industrial management.

Some dormitory facilities are provided. Fraternity houses provide living accommodations for their members. Scholarships, student loans, and work opportunities are available. Many students earn part or all of their expenses. *For statistics see* COLLEGES AND UNIVERSITIES. J. R. To.

**STEVENSON, ADLAI EWING** (1900- ), American lawyer and political leader, was born in Los Angeles, Calif., Feb. 5, 1900. His grandfather, of the same name (1835-1914), was Vice-President of the United States for the second Cleveland administration. The younger Stevenson attended public schools in Bloomington, Ill., where his family lived, Choate School and Princeton University, from which he graduated in 1922. After a year at Harvard Law School, he worked for the Bloomington Daily *Pantagraph* and then studied law at Northwestern University Law School. He was admitted to the Illinois bar in 1926 and, except for a brief period in Washington as a counsel for government agencies, practiced law in Chicago until Secretary of the Navy Frank Knox brought him to Washington in 1941 as his special assistant. In 1943 he headed a mission to Italy to plan occupation policies. He served as special assistant at the San Francisco Conference on World Organization in 1945 and, later that year, served as United States representative to the Preparatory Commission for the United Nations in London. At the first session of the United Nations General Assembly in 1946, he was senior adviser to the United States delegation and continued as a delegate until after the 1947 session.

In 1948 he was selected as the Democratic candidate for governor of Illinois and was elected by the largest margin in the state's history. As governor, Stevenson succeeded in eliminating much of the waste and political laxity that had existed in the state government, initiated improvements in state welfare and education, and launched an extensive highway reconstruction program. In 1952, in spite of his efforts to discourage a draft for the Presidency, the Democratic Convention nominated Stevenson on the third ballot. Running against the Republican nominee, Dwight D. Eisenhower, Stevenson conducted a vigorous campaign in which he displayed an ability to set forth issues in a stimulating and forthright manner and acquired national standing as a political leader of intellect and integrity. In the Republican landslide which marked the election, Stevenson won only 89 of the 531 electoral votes, although he received 27,312,217 popular votes as against 33,938,825 for General Eisenhower. In 1953 Stevenson made a six-month good-will tour around the world. W. Jo.

**STEVENSON, ROBERT LOUIS BALFOUR** (1850-1894), Scottish author, was born in Edinburgh, Nov. 13, 1850, of a family of eminent engineers. Stevenson, whose early schooling was broken by periods of illness, began to write at an early age. In 1868, following trips to Germany and Italy with his mother, he began to study his father's profession of civil engineering at the University of Edinburgh and in 1871 won the medal of the Scottish Society of Arts for a paper entitled *A New Form of Intermittent Lights for Lighthouses.* In this same year, because of his health, he gave up engineering and began the study of law. He was admitted to the bar in 1875, but never practiced.

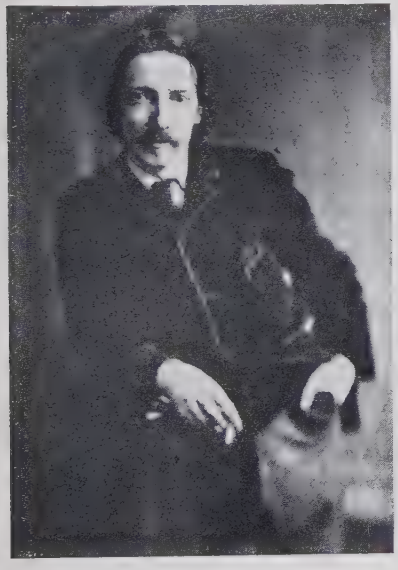
In 1873 Stevenson had met Sidney Colvin and other literary men. He began to contribute essays to magazines and then went on the wanderings in Scotland, France, and Germany which gave him the material for his first books, *An In-*

*land Voyage* (1878) and *Travels with a Donkey* (1879).

Stevenson fell in love with the American Mrs. Osbourne in France in 1876. She and her fourteen-year old son returned to their home in California in 1878, and, hearing of her sickness, Stevenson followed by steerage and immigrant train in 1879. Mrs. Osbourne's divorce enabled them to marry in May 1880, and that autumn they returned to Scotland. His health failing again, he spent the next two winters in Davos, and in the autumn of 1882 moved to the south of France, where he lived until in 1884 his health forced him to return to England. *Virginibus Puerisque* was published in 1881. In 1882 came *Familiar Studies of Men and Books* and in 1883 both *The Silverado Squatters* and the most famous of his boys' books, *Treasure Island,* which had earlier appeared in a magazine as *The Sea-Cook.*

With *Treasure Island,* a story of pirates and buried treasure, Stevenson's popularity began. It was enhanced by *A Child's Garden of Verses* (1885), *The Strange Case of Dr. Jekyll and Mr. Hyde* (1886), his most famous short story, *Kidnapped* (1886), one of his best longer stories, and *The Black Arrow* (1888).

In August 1887, after the death of his father, Stevenson left England and Europe for good. After some time spent at Saranac Lake under the care of a physician, he went to San Francisco and from there sailed to the Marquesas Islands. In Honolulu he finished *The Master of Ballantrae,* which had been begun at Saranac. About Christmas, 1889,



ROBERT LOUIS STEVENSON

Stevenson and his family landed at Samoa for a six-week stay, before going on to Sydney. The last four years of his life he spent in Vailima, on Samoa, where he became known as Tusitala by the natives, in whose affairs he took a great interest. *David Balfour,* a sequel to *Kidnapped,* was published in 1893. *The Ebb Tide* (1894) was the last of his books that he saw through the press. He was writing *The Weir of Hermiston,* which promised to be a more mature work than his earlier stories, when on Dec. 3, 1894, he died of an apopletic stroke and was buried by the natives on a hill overlooking the ocean.

Robert Louis Stevenson was romantic by temperament, in his adventurous life, and in all of his writing. His stories are of buccaneers, warring highlanders, knights and archers, swordplay, kidnappings, and escapes. In his essays he preached facing the bright face of danger, living life to the full, spending health like a spendthrift instead of hoarding it like a miser. Stevenson himself, his restlessness and vivacity accentuated by a tubercular feverishness, was tall, thin, dark-haired, brilliantly dark-eyed, something of a poseur in dress and manners. His personality attracted many who found his romanticism charming and admired the courage he showed through his lifelong ill health. It offended others, like Henry Adams, who visited him in Samoa in 1890 and thought him unclean in person and second-rate in talent.

Through imitating the style of other writers, playing "the sedulous ape," as he described it, Stevenson early attained great skill and dexterity in writing. All of his writing is marked by a surface perfection that is sometimes more noteworthy than its content. Stevenson wrote to entertain. He did not in his fiction attempt character creation or concern himself with social or ethical problems. The ideas he used were simple, often trite. Though he admired the sophisticated George Meredith, he wrote romances of adventure after the manner of Scott, Cooper, and Dumas, and decried the realistic approach adopted by the more serious novelists of the period. In *A Humble Remonstrance* (1884) he stated his belief that narrative is the most important element in fiction and that "the novel, which is a work of art, exists not by its resemblance to life . . . but by its immeasurable difference from life."

While acknowledging their excellence as almost perfectly written adventure tales dealing principally with childhood and youth, critics point accurately to an immaturity in Stevenson's fictional works. The same comparative immaturity is obvious in his optimistic, high-spirited essays, which are rhetorical and didactic, seldom profound. Though *Aes Triplex, Virginibus Puerisque,* and *Pulvis et Umbra* are better known, his delightful *The Lantern Bearers* shows Stevenson at his best as an essayist. J. P. Wo.

**STEVENS POINT,** a city in central Wisconsin, the county seat of Portage Co., on the Wisconsin River, in rolling agricultural country, about 120 mi. northwest of Milwaukee. George Stevens established a trading post with the Potawatomie Indians on the site in 1868. The town was surveyed in 1839 and incorporated in 1858. Stevens Point has the mayor-alderman form of government. The Central State Teachers College is located in Stevens Point, which has transportation facilities furnished by the Green Bay and Western and the Minneapolis, St. Paul & Sault Ste. Marie railroads. Local industries produce fishing tackle, automobiles, furniture, toys, and gas engines. Agricultural products of the region are potatoes, cheese, and butter. Pop. 1950, 16,564.

**STEWART, HOUSE OF.** *See* STUART (STEWART or STEUART), HOUSE OF.

**STEWART, ROBERT.** *See* CASTLEREAGH, ROBERT STEWART, VISCOUNT (MARQUIS OF LONDONDERRY).

**STEYR** or **STEIER** [shtai′r, shtai′ər], a city in north central Austria, in the province of Upper Austria, located at the junction of the Steyr and Enns rivers, about 20 mi. southeast of Linz in a rolling, wooded region. A manufacturing and tourist center, the city is dominated by the tenth-century Steyr Castle. The Stadt-Platz, the main town square, contains a number of seventeenth-century houses, a Renaissance courtyard bounded by three-storied arcades, and the Rathaus, which contains a great council chamber and dates from 1765. The Parish Church was built between 1443 and 1522, and the sacristan's house, south of the church, is noted as the place where Anton Bruckner completed his last compositions between 1886 and 1894. The manufacture of weap-

ons has been an important industry since the twelfth century. Steyr is the center of the Austrian iron industry. Other manufactures besides iron and steel goods include motor vehicles, bicycles, and leather goods. Pop. 1951, 36,818.
E. Ma.

**STIBINE.** *See* ANTIMONY.

**STIBNITE** [stɪ′bnait], antimony trisulphide, $Sb_2S_3$, an ore of antimony. It occurs in prismatic orthorhombic crystals which are vertically striated. The color and streak of stibnite are both lead gray. This mineral occurs in low-temperature hydrothermal veins. It is practically the sole ore of antimony in China, which, in normal times, produces more antimony than all the other countries combined. Iyo Province, Japan, has been the source of beautiful museum specimens of stibnite crystals. K. K. L.

**STICK INSECT,** the common name given to the members of the order Phasmida (sometimes considered a suborder of the Orthoptera). They have biting mouth parts; long antennae; long, slender legs; long, narrow bodies; and

COURTESY OF THE AMERICAN MUSEUM OF NATURAL HISTORY

*A stick insect of the family* Phasmidae, *native to the Trobriand Islands*

they may or may not be winged in the adult stage. Of the more than 2,000 known species, the vast majority occurs in the tropics, where the largest ones, some more than a foot in length, are found. As they rest on plants, they resemble dead twigs, and it is always a surprise to observe them as they begin to move. Some forms are parthenogenetic, no males having yet been discovered. Some are pests of hops; however, other plants may also be heavily attacked. *See also* LEAF INSECT.
C. H. Cu.

**STICKLEBACKS,** small fishes of the family Gasterosteidae, with isolated spines in front of the dorsal fin and a very slender caudal peduncle. Found in fresh and salt waters of temperate regions of the Northern Hemisphere, they are pugnacious and carnivorous, feeding upon small crustaceans and other invertebrates. They seldom exceed 4 in. in length. The three-spined stickleback, *Gasterosteus aculeatus,* is of circumpolar distribution and occurs on the Atlantic coast south of New Jersey. It also gets into fresh water in the Lake Ontario basin. The males build muff-shaped nests of plant materials that are fastened together by mucous threads secreted by their kidneys. After the eggs are deposited within the hollow center of the nest, the male guards them and the young. The brook stickleback, *Encalia inconstans,* is confined to fresh waters of North America. E. C. R.

**STIEGEL, HENRY WILLIAM** [sti′gəl; shti′gəl] (1729-1785), German-American glassmaker, sometimes called "Baron von Stiegel," was born near Cologne, Germany, May 13, 1729. He migrated to Pennsylvania in 1750 and went to work for John Jacob Huber, an ironmaster. Two years later he married his employer's daughter, Elizabeth, and in 1758 purchased Huber's furnace, which he rebuilt and named Elizabeth Furnace in honor of his wife. Stiegel became a prominent land owner and in 1762 founded the town of Manheim in Lancaster County, Pa. He began the construction of a glass factory in 1765, imported skilled workers from Europe, and started to manufacture glass and glass objects. Stiegel's glassware became famous and the individual pieces are now collector's items. However, Stiegel later went bankrupt. He died in Charming Forge, Pa., Jan. 10, 1785. A. W. Gr.

**STIEGLITZ, ALFRED** [sti′glɪts] (1864-1946), American photographer, was born in Hoboken, N. J., Jan. 1, 1864. He studied mechanical engineering, photochemistry, and photography in New York and in Germany until 1890, when he began writing, editing, and exhibiting his photographs. These masterpieces won prizes throughout the world and Stieglitz came to be regarded as the foremost photographic artist and theoretician in the United States. His writings were extensive, many appearing in *Camera Notes,* which he founded and edited from 1897 to 1903, and *Camera World,* which he edited and published from 1903. Stieglitz died on July 14, 1946. B. Su.

**STIGMATA** [stɪ′gmətə] (Gr. *στίγματα,* brand-marks), in a religious sense, the marks (wounds) of the Passion of Christ borne by many ecstatics on hands, feet, side, or brow, with corresponding intense sufferings. These sufferings, when occurring apart from the marks, are called invisible stigmata. The first known stigmatization is that of St. Francis of Assisi. In 1894, Imbert listed 321 stigmatics, including 62 saints or blessed. The fact of stigmatization is not disputed. Its supernatural character in certain cases is maintained by the Roman Catholic Church. The possibility of the phenomenon's being produced by natural causes is disputed.
N. J. T.

**STILICHO, FLAVIUS** [stɪ′lɪko] (c. 359-408), Roman general, was born about A.D. 359. He was a Vandal who entered the Roman army at an early age. Rising to a high military post under Emperor Theodosius, he was made Roman ambassador to Persia in 384. When Theodosius died in 395, he named Stilicho as the guardian of the young prince Honorius, who was to serve as emperor of the West. It was Stilicho who drove Alaric and the Visigoths from Greece in 396 and who defeated them again in 402 and 403 when they invaded Italy. Other triumphs were gained by Stilicho over the Ostrogoths in 405; at an earlier date he was successful in quelling a Moorish revolt in Africa. Honorius and Stilicho ultimately quarreled over the policy toward the Visigoths. Stilicho had hired them to campaign against the Eastern emperor, Arcadius, because this would keep them out of Italy and also weaken Arcadius. When Honorius accused him of treason, Stilicho might have initiated a revolt, but he refused. He was beheaded at Ravenna, Italy, Aug. 23, 408, by order of Honorius. T. B. J.

**STILL, WILLIAM GRANT** (1895- ), American Negro composer, was born at Woodville, Miss., May 11, 1895. A graduate of Oberlin Conservatory, he was twice awarded a Guggenheim Fellowship for creative work. He has used

the Negroid elements of jazz in developing his style, especially in *Lenox Avenue, A Deserted Plantation, Ebony Chronicle,* and the *Afro-American Symphony,* all works for symphony orchestra. Other works include the ballet *La Guiablesse,* Symphony in G Minor, and *Kaintuck,* for piano and orchestra. D. L. E.

**STILL LIFE,** that classification of painting in which inanimate objects furnish the principal subject matter, though they may be associated with persons or animals. Flowers, vegetables, fruit, meat, dead game, household utensils and *objets d'art* are the subjects most frequently used. Still life appeals to the observer in two ways: through association or experience with the objects in real life, and through purely pictorial or formal qualities. An emphasis on association is prominent in Dutch and Flemish work of the seventeenth century and continues generally until the late nineteenth century, when it is largely abandoned in favor of a greater interest in color, form, and design, without great regard for natural appearance.

Still life, as a separate art form, assumed importance in those periods in which its particular attractions were strong enough to inspire artists and furnish them a market for their work. Although examples are known from Hellenistic and Roman times, the modern development began with the Renaissance. The greatly expanded interest in the world and its contents, a familiar characteristic of that period, eventually led artists to an all-embracing desire to paint the objects and scenes of daily experience, and to an increased capacity for representing them. An interest in objects as such was particularly characteristic of the art of northern Europe, and by the early sixteenth century it had, at times, elevated them to a position of almost major importance in figure painting, especially portraiture. The seventeenth century, however, first saw the production of unmixed still life on a large scale. The schools of Holland and Flanders were especially noteworthy, producing such masters as Jan Weenix, Frans Snyders, Jan de Heem, and Willem Kalf, who, in a finely detailed technique, reflected a native delight in the materials of ordinary existence. From this time on, the taste of the growing middle class maintained a steady market for pictures of this type, and some of the pictures reached a level of extraordinary excellence, as in the work of Jean-Baptiste Siméon Chardin (1699-1779), who combined associative pleasure with exquisite formal harmony.

The advent of the progressive modernism of the late nineteenth century produced a greater concern for matters of style and form in painting. One result of this tendency was that still life in the hands of Paul Cézanne, and later on, the Cubists, became a complex study of line, color, shape, and volume in which natural objects as a pleasing factor in ordinary experience largely disappeared. J. C. S.

**STILLWATER,** a city in southeastern Minnesota, the county seat of Washington Co., situated on the St. Croix River, on the Wisconsin border, 16 mi. northeast of St. Paul, in a fertile area of dairying and diversified farming. Founded about 1839, Stillwater was made the county seat in 1840; it was incorporated as a town in 1844 and as a city in 1854. Stillwater's government is the mayor-council-manic type. About the middle of the nineteenth century Stillwater was a bustling, "wide open" logging town. A striking geologic feature is the exposed layer of Jordan sandstone that lies along the river at Stillwater. The Minnesota State Prison is in the city. Transportation is afforded by river craft and the Chicago and North Western, the Northern Pacific, and the Chicago, Milwaukee, St. Paul and Pacific railroads. Lumber, clothing, men's shoes, binding twine, flour, road machinery, and tractors are among the products produced by local industries. Pop. 1950, 7,674.

**STILLWATER,** a city in north central Oklahoma, the county seat of Payne Co., located 75 mi. northeast of Oklahoma City. It is served by the Atchison, Topeka and Santa Fe Railroad. The city is an important distribution point for livestock, dairy products, poultry and small grains. The little industry that exists in Stillwater is confined to the processing of farm products. Stillwater is the seat of Oklahoma Agricultural and Mechanical College. The city was founded by settlers from Kansas in 1889. Pop. 1950, 20,238.

**STILT,** any one of several wading birds in the genera *Himantopus* and *Cladorhynchus,* allied to the avocets, which are found in temperate and tropical regions throughout most of the world. They are characterized by having extravagantly long legs, usually colored red, and their plumage is various combinations of black, white, gray, and rufous. Stilts inhabit sloughs and lagoons of fresh or brackish water, where there is abundance of aquatic vegetation, and feed upon minute forms of animal life. They are famous for the extraordinary vocal demonstrations with which they express solicitude for their eggs or young. The American or black-winged stilt, *Himantopus himantopus mexicanus,* which measures about 15 in., is a common species in the western United States and also appears in the Gulf States. H. G. De.

**STILWELL, JOSEPH WARREN** (1883-1946), American army officer, was born in Palatka, Fla., Mar. 19, 1883. He was graduated from West Point in 1904, and served with the American forces in France during World War I. After the war, he spent several years with American units in China. From 1935-1939 he served as military attache at Peiping, and in 1942 he returned to China, with the rank of lieutenant general and was placed in command of the 5th and 6th Chinese armies in Burma. Later that year Stilwell also received command of all United States forces in the China-India-Burma theatre of war. His outnumbered, inadequate troops were routed in Burma and forced to retreat; two years later Stilwell publicly criticized the British Admiral Lord Louis Mountbatten for failing to launch a full-scale offensive in Burma. Stilwell's uncompromising directness and his desire for efficiency led to his serious disagreements with Chiang Kai-shek; he was recalled to the United States in November 1944 and made commander, as a full general, of the United States Army Ground Forces. He was given command of the 10th army in the Pacific theatre of war in June 1945, but in September, after the war had ended, he was again assigned to the United States. He died in San Francisco, Calif., Oct. 12, 1946. In 1948 Stilwell's diaries and letters were published as *The Stilwell Papers.* R. W. Cr.

**STIMSON, HENRY LEWIS** (1867-1950), American statesman, was born in New York, N. Y., on Sept. 21, 1867. After attending Phillips Andover Academy, he studied at Yale, where he graduated in 1888. He was then graduated from Harvard Law School in 1890 and was admitted to the New York bar in 1891. Stimson practiced law privately in New York City until 1906, at which time he was appointed United States Attorney for the Southern District of New York by President Theodore Roosevelt. Defeated as Republican nominee for the governorship of New York in 1910, he was made secretary of war in 1911 by President William

H. Taft. Not in government service during President Woodrow Wilson's administration, Stimson helped Governor Alfred E. Smith reform the New York State Constitution in 1915. During World War I, he served as a colonel of field artillery in France. In 1927, he was appointed by President Calvin Coolidge to arbitrate a dispute concerning the presidency of Nicaragua.

From 1927 to 1929, Stimson was governor general of the Philippines, and in 1929 he became secretary of state under President Herbert Hoover, where he gained a reputation as

*HENRY LEWIS STIMSON*

CULVER SERVICE

an interventionist. He was chairman of the American delegation to the London Naval Conference in 1930, and after Japan invaded Manchuria in 1931 he fathered the "Stimson doctrine" of nonrecognition of territories and agreements acquired by acts of aggression. He was a strong advocate of the Kellogg Pact (1932), which outlawed war, and in the same year was in charge of the American delegation to the Geneva Disarmament Conference. Stimson believed in increasing income taxes for the wealthy and in universal military training; as secretary of state, he was the first in United States history to have a military aide. With the election of President Franklin D. Roosevelt in 1933, he resumed his private law practice, but supported Roosevelt's foreign policies. In 1937, he was elected president of the New York City Association of the Bar. Stimson advocated the discontinuance of supplies for Japan and was a supporter of Cordell Hull's proposed neutrality bill prior to World War II. At the outbreak of World War II (1939), Stimson proposed compulsory military training and a foreign policy whereby Great Britain could obtain American supplies and munitions. He was secretary of war under President Roosevelt from July 1940, to April 1945, when he retired. Stimson wrote *American Policy in Nicaragua* (1927), among other books, and was co-author of *On Active Service in Peace and War* (1948). He died in New York, Oct. 20, 1950. W. E. A.

**STING RAYS,** common name of the Dasyatidae, a family of rays which resemble skates. The whiplike tail is armed with a long spine or sting on the upper side. This sting, which may be up to 15 in. long in the larger species, is saw-toothed. It is used both as a defensive and offensive weapon. At times the ray circles its prey and, by constantly lashing its tail, strikes it with the sting until it is cut to pieces. Men are sometimes attacked and a surgical operation is occasionally required to remove the broken off spine. It causes horrible pain and in a few cases even death. Ancient writers long suspected and it is now proven that a poison is present. The venom is secreted by cells of glandular tissue which line a narrow groove on either side of the spine. Sting rays are found in most warm seas and enter fresh water. The larger ones may be 6 ft. across the disk and weigh about 60 lb. The northern sting ray, *Dasyatis centrura,* is found along the Atlantic coast from Maine to North Carolina and may reach a length of 12 ft. E. C. R.

**STINKBUG,** the common name given to any member of the family Pentatomidae, of the order Hemiptera. The majority are subtriangular or shield-shaped, being widest just behind the head. On their abdomen there are scent glands that give off an odor that is offensive to most animals. The family contains both predaceous and herbivorous forms, including some that will both suck the juices of plants or feed on other insects. The harlequin cabbage bug, *Murgantia histrionica,* is a pest of cruciferous plants. One of the most interesting of the predaceous species is the friendly perillus, *Perillus occulatus,* which feeds upon potato beetle

*A GREEN AND ORANGE STINKBUG OF THE FAMILY PENTATOMIDAE, AN INSECT WHICH EMITS A DISAGREEABLE ODOR*

COURTESY OF THE AMERICAN MUSEUM OF NATURAL HISTORY

larvae and has at times become so abundant as to render spraying unnecessary. Some of the tropical stinkbugs are an inch long and beautifully colored. C. H. Cu.

**STINKHORN,** a fungus, *Ithyphallus impudicus,* known for its putrid odor. It is found in open woods, in fields, and on lawns in late summer and early autumn. It grows about 3 to 5 in. tall and has a stem about 1 in. in diameter. It is not surmounted by a gilled cap, as the true mushroom is, but by a pitted, darkened cap in which the spores develop. The cap is covered by a mucouslike substance having a repulsive odor. Flies attracted by this penetrating smell carry the spores to other locations. J. C. Wis.

**STINKWOOD,** a large South African tree, *Ocotea bullata,* of the laurel family. Its hard, durable, ill-smelling wood is valued for shipbuilding. The name is sometimes applied to several other trees having malodorous wood, including *Nyssa sylvatica,* of the tupelo family, native to eastern North America, and stinkwood hackberry, *Celtis kraussiana,* a South African of the elm family, both of which produce useful timber; also Carolina buckthorn, *Rhamnus caroliniana,* an ornamental of the buckthorn family found in southeastern North America. J. C. Wis.

**STIRLING** [stɜ′rlɪŋ], a shire and its administrative burgh, located in central Scotland.

**The City.** The city of Stirling, situated on the Forth River, is a port and rail center, about 25 mi. northeast of Glasgow. The Romans had a station on the site, but the origin of the castle is unknown. Stirling's first known charter was granted by Alexander II in 1226, and the last governing charter was given by Charles I in 1641. For over five hundred years a royal residence and capital, the castle was the deathplace of Alexander I in 1124 and that of William the Lion in 1214, and it was the birthplace of James II in 1430, probably that of James IV in 1473, and that of James V in 1512. Monarchs crowned at the parish church were Mary Queen of Scots and her son, James VI. The castle is used as a barracks. However, the Chapel Royal is preserved, and on the walls in 1946 were uncovered the insignia of James VI, painted between 1600 and 1610. A staircase leads to the Douglas Room, kept as a museum, where James II stabbed Douglas in 1452. Stirling surrendered to the English in 1296, but Wallace recaptured it in 1297. Carpet weaving, wool spinning, cattle marketing, and the manufacture of rubber, confectionery, and farm implements comprise the principal industries. Pop. 1952, 26,824.

**The County.** Stirling County, known for its coal mines, has an area of 451 sq. mi. It is bounded by Perthshire on the north, Clackmannanshire and the Firth of Forth on the east, West Lothian and Lanarkshire on the south, Loch Lomond and Dumbartonshire on the west. It is a county of contrasts, from the wild highlands of the Fintry Hills, Gargunnock and Kilsyth Hills, the highest peak of which is Ben Lomond, with an elevation of 3,193 ft., to the lowlands with their well-developed coal measures. The eastern part of the county is flat and well cultivated. Coal, iron, limestone, and sandstone are abundant. Iron manufactures are the staple industry, and there are woolen and cotton mills, large chemical works, and distilleries. Falkirk, Kilsyth, and Grangemouth are important centers, in addition to the county town, and four rivers—the Forth, Avon, Endrick, and Carron—water the region. Stirlingshire unites with Clackmannanshire to return two members to Parliament. Pop. 1952, 188,239. A. W.

**STOAT,** the large weasel, *Mustela erminea,* of Europe. When in the summer pelage of brown, the animal is referred to as a stoat. On changing to white in winter, the animal becomes an ermine. The term "stoat" should be considered synonymous with weasel. *See also* WEASEL. W. J. Ha.

**STOCK, FREDERICK AUGUST** [stɒ'k] (1872-1942), German-American orchestral conductor, was born in Jülich, Germany, Nov. 11, 1872. He attended the Cologne Conservatory and from 1891 to 1895 was a violinist in the Cologne orchestra; in 1895 he became leader of the viola section in the Thomas Orchestra of Chicago and was appointed assistant conductor of this organization in 1901. In 1905, following Thomas' death, he became permanent conductor and retained this position until his death on Oct. 20, 1942, in Chicago. Stock was noted for his interpretation of modern German music and for the general excellence of his orchestra. He composed a symphony and other works but is distinguished in this field only for his technical mastery. E. L. F.

**STOCK.** *See* BANKING, INVESTMENT.

**STOCK,** a genus, *Mathiola,* of downy herbs or subshrubs of the mustard family, having oblong or narrow leaves and terminal clusters of mostly purplish flowers. There are about 500 species, mostly native to the Old World and Australia. Common stock, *M. incana,* native to the Mediterranean region, is an erect, branching, biennial or perennial herb, growing as high as 2½ ft.; it is cultivated ornamentally in many varietal forms for its autumn bloom. Ten-weeks stock, *M. i.* var. *annua,* a summer-blooming annual, is extensively grown for the florist trade. Grecian stock, *M. bicornis,* is valued for the fragrance of its small, purplish flowers, which open in the evening. J. C. Wis.

**STOCK, VIRGINIA,** *Malcomia maritima,* a plant of the mustard family, closely related to stock. It is an attractive hardy annual from the Mediterranean region, growing about 1 ft. high. The lilac, red, or white flowers are veined at the base of the petals. Plants will bloom all summer if successional sowings are made. J. C. Wis.

**STOCKBROKER.** *See* BANKING, INVESTMENT (*Organized Security Exchanges*); BANKING INSTITUTIONS.

**STOCK CONTROLS.** *See* INDUSTRIAL TECHNIQUES (*Industrial Controls*); MARKETING AND MERCHANDISING (*Merchandising*).

**STOCK EXCHANGE.** *See* BANKING, INVESTMENT; BANKING INSTITUTIONS.

**STOCKHOLM** [stɒ'khom; stɔ'khɔ'lm], the capital of Sweden and of the county, or *län,* of Stockholm, located in southeastern Sweden on the Baltic Sea.

**The City.** The largest city, port, and manufacturing center in Sweden, Stockholm is situated at 59° 20′ N. lat. and 18° 03′ E. long. at the outlet of Lake Mälar where it flows into the Baltic Sea. The surrounding country is broken into great rock blocks separated by two systems of geologic faults, which have cliffs on their margins and water-filled channels between the blocks. Today these channels serve as the port of Stockholm, notably the steamship port on Lilla Värtan, while the cliffs form considerable eminences within the city, such as the 150-ft. escarpment of Södermalm on the southern mainland. A glacial esker, a long, low, sinuous ridge, was deposited in ancient times upon this rock base and became an early route of communications, since it reached the shores at Saltsjön, the narrowest point, where crossing was possible. The region of Stockholm is heavily forested with many coniferous growths interspersed with extensive rock exposures. Stockholm's annual temperature ranges from 29° F. in January to 62° F. in July. The average annual rainfall is 20.7 in.

*Industries and Transportation.* Stockholm is the largest manufacturing city of Sweden and its largest importer, although it is exceeded in exports by Göteborg. Industries include mechanical and electrical machine works, shipyards, sawmills, rubber factories, motion pictures, and the manufacture of metals, paper, textiles, porcelain, and ironware. The city is well served by railways extending to all parts of Sweden and connecting via Denmark with the Continent and via Oslo with Norway. Shipping lines reach to Finland and the entire Baltic as well as many world ports. Airlines lead to all of Europe and South and North America. Pop. 1952, 761,727.

**Buildings and Educational Institutions.** Stockholm is a modern city and an outstanding example of carefully studied town planning, with many co-operative housing developments, broad avenues, and numerous parks. It is the seat of the Nobel Institute, and the annual Nobel Prize awards are made in Stockholm's Concert Hall.

Notable buildings in Stockholm form two groups: those built in the monumental style of previous centuries, and those erected during the rebirth of Swedish architecture in the twentieth century. The older buildings are confined

mostly to the islands of Staden and Riddarholmen, bounded by the Saltsjön to the east, Lake Mälar to the west, and the Söderström and Norrström, which connect these bodies of water. Here are located the Royal Palace (1754); St. Nicholas Cathedral, built in the mid-thirteenth century; the Riddarholmskyrkan, the Swedish Pantheon, which is the tomb of many Swedish kings and nobles; and the Börs or Exchange and the Arvfurstens palats, built in the 1770's and 1780's. The newer structures include the Royal Opera House (1898); the Swedish Parliament Building (1905); the Royal Dramatic Theatre (1908); the Stadshuset or Town Hall, Stockholm's most famous landmark, built by Ragnar Östberg in 1911; several new hospitals; the Stadium, built for the 1912 Olympic Games; and many modern office buildings and two modern churches, all contributing to Stockholm's contemporary look. To the east of Staden is the island of Djurgrden, which contains a natural park and an open-air museum called Skansen. Many museums and large sports centers can be found in Stockholm. Modern suburbs to the west of the city represent the newest ventures in city planning. The College of Science and Engineering, or Tekniska Högskolan (1914-1929), is the oldest institution of higher education in Stockholm. It was founded as The Technological Institute in 1825. Others include the Karolinska Institutet (1810); Stockholm University (1877); the Stockholm School of Economics (1909); and several other institutions.

*History.* Stockholm's founding date is given as 1252, but a fishing village was located on the site previous to that time. The city's development began with the building of a strong castle on the Norrström waterfront by Birger Jarl in 1252, to guard Lake Mälar against pirate raids, and shortly thereafter when the king moved his headquarters from Uppsala to Stockholm, giving the town political and commercial importance. Business in Stockholm at that time was in the hands of German merchants from Lübeck, who held a privileged position until 1471. During the Middle Ages, Stockholm remained the *Staden mellan broarna,* the town between the bridges, since it was confined to the islands of Staden and Riddarholmen, which are separated from the north shore, Norrmalm, and the south shore, Söderlmalm, by streams. With the advent of the Vasa Dynasty in 1523, the city became the center of government and the treasure of the realm was moved to Stockholm, which gained importance as the country grew, particularly under Gustavus Adolphus. During the reign of John III (1568-1592) the monumental style and rectangular street pattern of the Italian Renaissance were inaugurated to replace the Gothic architecture of the older city. The old castle of the Three Crowns was destroyed by fire in 1697 and replaced in 1754 by the present Renaissance structure. The power of Sweden diminished during the late seventeenth century and slowed its progress. By 1850 the modern era had begun in Sweden, and by 1900 the city grew from 93,000 to 300,000. Stockholm assumed industrial importance early in the nineteenth century.

**The County.** The rural district, county, or *län* of Stockholm includes a series of lakes and bays, which penetrate the interior of central Sweden, and covers an area of 3,041 sq. mi., of which 55 mi. are occupied by the capital, which is administered separately. Many of the most important Swedish industries are located in the area. Lake Mälar and the canal system provide inexpensive transportation for the mineral resources of the interior. Historically, the region is a center of political and social life, having within it many of the famous houses of the nobility. Pop. 1952, 371,598, excluding the city proper.

**STOCKHOLM BLOOD BATH** (Nov. 8-9, 1520), a massacre of Swedish nobles and patriots by Christian II of Denmark. Christian had invaded Sweden in 1520 to put down a Swedish revolt and regain the throne. The widow of Sten Sture the Younger, Christina Gyllenstierna, led the defense of Stockholm until further resistance was useless. After Christian promised amnesty to the Swedish leaders, the gates of the city were opened and Christian entered, eventually to be crowned king of Sweden. In the midst of the coronation celebration the King had many of the former rebels seized. Eighty-two were executed the first day and others later; their bodies were burned. The bodies of Sten Sture the Younger and his infant son were exhumed and also burned. Although the King assumed responsibility for the massacre, Gustav Trolle, the Archbishop of Uppsala, and Didrik Slaghaek were guilty of urging him to the act. When Christian left Stockholm in December 1520, he took with him several hostages. The massacre impelled the Swedes to revolt and eventually was the cause of the dissolution of the Union of Kalmar, binding Sweden, Norway, and Denmark. It also gained for Christian the epithet "the Cruel."

R. E. L.

**STOCKPILING.** *See* Industrial Production (*Raw Materials and Accessory Resources*).

**STOCKPORT,** a municipal, county, and parliamentary borough, partly in Lancashire, and partly in Cheshire, England, 160 mi. northwest of London, where the Tame and Goyt rivers join to form the Mersey. Situated in a coal mining district, it is an important industrial and railroad center. It was once a Roman military station. Stockport, enfranchised in 1832 and incorporated in 1835, was made a county borough in 1888. Industries include cotton bleaching, dyeing, and weaving and the manufacture of felt hats, motors, machine and electrical goods, and food products. The town returns two members to Parliament. Pop. 1952, 141,000.

A. W.

**STOCK SAVINGS BANKS.** *See* Banking Institutions.

**STOCKTON, FRANCIS RICHARD** (1834-1902), American novelist and short-story writer, was born Apr. 5, 1834, in Philadelphia. His family intended him for a career in medicine, but in 1852 he became a wood engraver, demonstrating his success by inventing a double graver in 1866. In 1867 he began contributing to the *Riverside Magazine for Young People,* and his stories were later collected in *Ting-a-Ling* (1870). With this encouragement, Stockton finally abandoned art for journalism and during 1872 and 1873 was associated with the Philadelphia *Post, Scribner's Monthly,* and *Hearth and Home.* His longest employment was as assistant editor of *St. Nicholas* from 1873 to 1881 under Mary Mapes Dodge, but after eight years his success with fiction enabled him to retire from journalism. He died in Washington, D. C., on Apr. 20, 1902.

Stockton is remembered primarily for a single short story, "The Lady or the Tiger" (1884), which at the time of its publication created a popular sensation; its novel conclusion, leaving a choice of endings to the reader, assures it a lasting, if minor, place in literature. Stockton's other short stories, filling twelve volumes, have been forgotten, but of his novels at least two are minor classics of humor: *Rudder Grange* (1879), a burlesque account of an expedition in a houseboat; and *The Casting Away of Mrs. Lecks and Mrs. Aleshine* (1886), a farcical story of adventures following a

shipwreck. A great wit and a born story-teller, Stockton was particularly skillful in inventing a ridiculous or grotesque situation and spinning a whimsical tale around it; he was a master of the implausible. W. P. R.

**STOCKTON,** a port city and the county seat of San Joaquin Co., in western California, situated at the head of the tidewater on the San Joaquin River, 49 mi. south of Sacramento. With the completion of Stockton's 88-mi. deep-water channel to San Francisco Bay in 1933, the city became the state's major inland port. Along the harbor are facilities for ocean-going vessels, grain elevators and conveyors, and warehouses. Much of the city's industry is dependent on the livestock and varied produce of the fertile San Joaquin Valley, whose crops include wine grapes, nuts, sweet cherries, asparagus, celery, and tomatoes.

A community was founded on the city's site in 1844. Because of its location on navigable waters for seagoing vessels, Stockton became an important supply point for the Mother Lode mining area, which opened up in the vicinity after 1848. In 1850 when California became a state, Stockton was incorporated and made the county seat. It continued as the trade center not only for the mine district, but also for the large farm population and lumber interests which moved into the valley. Stockton has the city-manager form of government. Located in the city are the College of the Pacific and Stockton Junior College. Sites of interest include the Civic Memorial Auditorium, the county court house, the Haggin Memorial Galleries, and the San Joaquin Pioneer Historical Museum.

In addition to the ocean steamers, the Atchison, Topeka and Santa Fe, the Southern Pacific, the Central California Traction, the Stockton Terminal and Eastern, the Tidewater Southern, and the Western Pacific railroads and the United Air Lines provide transportation. The city's chief industries produce wine, evaporated milk, processed foods, tools and dies, wooden crates and containers, farm implements, and feeds. There are large wholesale houses, shipyards, canneries, and grain elevators. Pop. 1950, 70,853. S. D. M.

**STOCKTON-ON-TEES,** a municipal and parliamentary borough and port in Durham, England, on the Tees River, 5 mi. from its mouth on the North Sea and 236 mi. northwest of London. Situated in a coal and iron region, it is an important port and industrial and farm-market town. Stockton grew up around the manor of the bishops of Durham, to whom the town belonged. The borough's records date back to 1283. In the fifteenth century it was held by a bishop's bailiff; in 1652 the castle was dismantled; and during Oliver Cromwell's time a representative in Parliament was allowed. The discovery of coal broke the hold of the barons and bishops over the district. In September 1825, service was inaugurated on the first railroad passenger train from Stockton to Darlington. The chief industrial establishments are shipbuilding yards, iron foundries, boiler works, and agricultural markets. Pop. 1952, 73,820. A. W.

**STOICISM** [sto′ɪsɪzəm]. Founded by Zeno of Citium a little before 300 B.C. in Athens, Stoicism, along with Epicureanism, ushered in the new Hellenistic age in philosophy, and it was destined to become the most influential school until supplanted by Neo-Platonism, the final formation of Greek philosophy in the third century of the Christian Era.

After Zeno's suicide (c. 260 B.C.) Cleanthes, the poet, presided over the school from 264 to 232 but he was not able to answer the opponents of Stoicism and to advance his cause. Chrysippus, succeeding him from 232 to 206, reorganized and reinvigorated the movement.

Our information concerning the next two centuries is far from complete. Panaetius of Rhodes (c. 180-110 B.C.) organized Stoicism in Rome, and Posidonius (c. 130-c. 50 B.C.), emphasizing religious speculation, seems to have influenced Philo of Alexandria. The works of Cicero (106-43 B.C.), who was not a Stoic, today furnish a most important source of information on the Stoic theories; and still extant are the works of the great Stoics, Epictetus (A.D. 50-130) and Marcus Aurelius (A.D. 121-180).

The Stoics divided philosophy into three areas: logic, physics, and ethics. Under the heading of logic they made a minute investigation of grammar, but their more fundamental concern was to defend the possibility of truth. Rejecting the sophistical conclusions of pre-Socratic philosophy, and yet not admitting the supersensuous realities of Plato, they thought that another attempt should be made to base truth on sense experience. This attempt requires the existence in the mind of an impression infallibly distinguishable from every false impression, a mental image that attests its own accuracy—an assumption constantly attacked by the Academicians and Skeptics.

The Stoic epistemology was dictated by the Stoic materialistic physics, which held that everything real is a body occupying space, and that, since qualities are real, they, too, are bodies. From this it follows that two bodies can occupy the same space. Obviously, then, bodies are not aggregates of impenetrable atoms moved by impact; rather, as Heraclitus suggested, the world is a dynamic continuum. According to a biological analogy, which was proposed, the particular things of the world are governed in their emergence and development by the inherent power of seeds—sparks, as it were—of the divine reason.

The underlying substance of the world, this divine reason, is an intelligent fire that directs all events. Nothing occurs by chance; everything is governed by Fate. Accordingly, in the religious practice of divination, while the entrails of the victim are not the cause of tomorrow's victory, their condition is consonant only with a world in which this army will be victorious tomorrow. By Fate, universal history goes its determined way: a gradual increase of fire will entirely consume the present order, and a new world will be born to run its course as an exact duplicate of all previous worlds.

Fatalism, however, is not destructive of morality, either theoretically or practically. Theoretically, morality is based not on an uncaused free will, but on voluntary action. A man is responsible for the act he wills. Whether or not he could have willed differently is an idle question. The Stoics exemplified morality in their conduct, and, as time went on, they emphasized it more and more in their writings. The *summum bonum,* according to the Stoics, is rational action, a life according to nature, not bestial nature as in Cynicism, but a life of virtue; to desire the impossible is irrational; and, therefore, we should concern ourselves only with what is in our power—not wealth, pleasure, or reputation, but our inward reaction to the circumstances of life. G. H. Cl.

**STOKE-ON-TRENT,** a city in Staffordshire, England, a county and parliamentary borough, and a railroad center on the Trent River, about 30 mi. south of Manchester and 135 mi. northwest of London, in the famous pottery district known as the Potteries. Stoke-on-Trent was municipally federated with Hanley, Burslem, Longton, Fenton, and Tunstall in 1910, and in 1925 the merged communities were made a city. Stoke was first incorporated in 1874, but

Hanley is mentioned in the Domesday Book. Arnold Bennett, who was born near Hanley, made the "Five Towns" as he called the communities, known over the world through his novels. Josiah Wedgwood, Josiah Spode, Herbert Minton, and W. J. Copeland are names famed in connection with the local pottery industry. The North Staffordshire Technical College has the Solon Library on ceramics, one of the finest in the world. The coal mines and coarse clay pits in the region furnish the basis for the famed potteries. The finer clays used are imported. In addition to porcelain and earthenware, manufactures are aluminum, brick, tile, sanitary ware, electrical porcelain fittings, and tires. The city returns three members to Parliament. Pop. 1952, 272,300. A. W.

**STOKES, SIR GEORGE GABRIEL** (1819-1903), British mathematician and physicist, was born Aug. 13, 1819, in Skreen, County Sligo, Ireland. He entered Pembroke College, Cambridge, and became a fellow in 1841. He remained at Cambridge all his life, being appointed Lucasian Professor of Mathematics in 1849. Two papers by Stokes, dated 1845 and 1850, presented the theory of motion through viscous fluids. He formulated the classic equation for the terminal or steady velocity of a small sphere, such as a raindrop, falling in a viscous medium, such as air. By the year 1849, Stokes had also published papers discussing Newton's rings and the diffraction, interference, and polarization of light. In 1852 Stokes established the fact that the wave length of fluorescent light is always longer than that of the radiation being absorbed by the fluorescing material. He himself utilized the word "fluorescence" because of his observations of the phenomenon in fluorite.

Among Stokes's contributions to science are studies relating to convergence in infinite series, a theorem in vector analysis that bears his name. He also discovered that a reflected ray of light suffers a change of phase of one-half wave length.

Stokes was secretary to the Royal Society from 1854 to 1885 and served as its president for the five-year period commencing in 1885. From 1887 to 1891 he was a representative of Cambridge University in the House of Commons. He became a baronet in 1889. He also received many scientific honors. The stoke, a unit of viscosity, is named for him. Stokes died at Cambridge on Feb. 1, 1903. I. B.

**STOKOWSKI, LEOPOLD** [stɔkɔ'fski] (1882- ), English-American orchestral conductor, was born in London, Apr. 18, 1882, of a Polish father and an Irish mother. After studying composition and organ in London, he became organist and choirmaster at St. Bartholomew's in New York, and from 1909 to 1912 he was conductor of the Cincinnati Symphony Orchestra. From 1912 to 1936 he conducted the Philadelphia Orchestra, which in his hands became one of the great orchestras of the world. Since 1936 he has conducted such orchestras as the NBC Symphony Orchestra, the New York City Symphony, the Hollywood Bowl Symphony, and the New York Philharmonic. He has also appeared in several motion pictures. W. Li.

**STOMACH,** a hollow, muscular, and secretory digestive organ, connected with the esophagus at one end, and with the duodenum at the other. It forms the most dilated portion of the alimentary tract and is situated in the upper left part of the abdomen.

**Anatomy.** The size, shape, and position of the stomach show considerable variations, depending on body-build, posture, and tonus. The normal stomach is often J-shaped and has a capacity of from 1,000 to 1,500 cc. The upper outline is concave and is known as the lesser curvature; the lower outline is convex, about three times longer than the lesser curvature, and is known as the greater curvature. The stomach is usually divided into three parts: pars cardiaca, or fundus; pars media, or the body; and pars pylorica, or antrum. The cardiac sphincter is located at the juncture of the stomach and the esophagus; the pyloric sphincter guards the entrance to the duodenum. The entrance to the stomach is kept open by a small air bubble. The walls consist of four coats.

The innermost coat of the stomach is a mucous membrane. It contains numerous glands, of which the fundic glands secrete pepsinogen, renninogen, and hydrochloric acid, or its precursor. The pyloric glands secrete mucigen and proenzymes for pepsin and rennin. The second coat, known as submucosa, consists of loose fibers of connective and elastic tissue, containing nerves and blood and lymph vessels. The third coat is muscular, with three layers of muscles, of which the outer are longitudinal, the middle, circular, and the inner, oblique. The fourth coat is known as the serosa and consists of the peritoneum which closely covers the entire stomach, except at the curvatures where the peritoneum is reflected to the lesser and greater omenta.

The high level of secretory and motor activity of the stomach requires an abundant blood supply. The stomach is amply supplied with blood from the celiac axis. The main drainage of the venous blood is into the portal vein. Innervation of the stomach plays an important role in its functional disorders. The nerve supply of the stomach comes exclusively from the autonomic nervous system, of which the parasympathetic division is represented by the vagus nerve, and the sympathetic by branches from the celiac plexus.

**Physiology.** The stomach has a secretory and a motor function. The fundus serves largely as a reservoir for the ingested food, softening and saturating it with gastric juice. There is little peristalsis in this section. When the food enters the stomach, it is saturated with salivary secretion, and the diastatic action of this secretion continues for a while in the fundus, until it is checked by the acidity of the gastric juice. Psychic factors are of considerable importance in the secretion of the gastric juice, and it is well known that shock and grief may inhibit or suppress this secretion.

Gastric juice contains from 0.4 to 0.5 hydrochloric acid, and also chlorides of sodium and potassium, nitrogenous elements, and phosphates. The mucin in the juice protects the gastric mucosa from injury. The gastric juice also has antiseptic value. Its digestive function consists in softening the cellulose fibers and in starting the digestion of proteins, converting them to peptones. Normal gastric secretion also has a definite relation to normal blood formation and is of importance in calcium and iron metabolism.

The motor function of the stomach consists of active peristaltic waves in the antrum which churn and macerate the food, preparatory to its ejection, in small portions, into the duodenum.

**Pathology.** The stomach is subject to several functional and organic disorders. Among them are dysfunctions of gastric secretion, such as hypoacidity and hyperacidity; gastritis; peptic ulcer; and carcinoma. *See also* Dyspepsia; Gastritis; Peptic Ulcer; Surgery; Tumors. B. Van R.

**STOMATITIS.** *See* Foot-and-Mouth Disease.

**STONE, HARLAN FISKE** (1872-1946), American jurist and educator, was born at Chesterfield, N. H., Oct. 11, 1872. He was educated at Amherst College, where he grad-

uated in 1894, and at Columbia University Law School, where he received his LL.B. in 1898. He was admitted to the New York bar in the same year. In 1899 he returned to Columbia as a lecturer on law, and in 1902 was appointed professor, retaining the post until 1905; from 1910 until 1923 he was dean of the Columbia School of Law. In 1924, President Calvin Coolidge appointed Stone United States Attorney General and, in 1925, an associate justice of the United States Supreme Court. In 1941, in succession to Charles E. Hughes, President Franklin D. Roosevelt appointed him Chief Justice. Among Stone's books is *Law and Its Administration* (1915); his wide knowledge of his subject and the precision with which he used this knowledge earned the respect of his contemporaries. Stone died in Washington, D. C., Apr. 22, 1946. R. T.

**STONE, LUCY** (1818-1893), American reformer and women's rights leader, was born on a farm near West Brookfield, Mass., Aug. 13, 1818. Refused a college education by her father, she studied at home, taught school, and then worked her way through Oberlin College from which she graduated in 1847. She at once began lecturing, particularly in the interests of the anti-slavery movement and women's rights. She participated in the first national Women's Rights convention in 1850. In 1855 she was married to Henry Brown Blackwell (1824-1909), but kept her maiden name. In 1858, while living in New Jersey, she allowed her household goods to be sold for taxes and then published a protest pamphlet on "taxation without representation." Active in the movement for woman suffrage and equal rights, she devoted much of her time to lecturing in their interest. She helped found the *Woman's Journal* in 1870 and two years later she and her husband assumed its joint editorship, which they retained for the remainder of their lives. She died in Dorchester, Mass., Oct. 18, 1893. T. R. H.

**STONE AGES.** *See* Archaeology (*Prehistoric Archaeology*).

**STONE BORER,** the popular name for bivalve mollusks which bore into stone. They belong to three different genera; the date shells, *Lithodomus,* the piddocks, *Pholas,* and *Saxicava. Lithodomus* is found in Florida, the West Indies, and Europe. When young it attaches itself by byssuses but later on bores into the stone, forming a hole to fit its shell. *Saxicava* is nearly cosmopolitan in distribution. It is very common north of Cape Cod, burrowing in limestone. *Pholas,* with an elongated and very convex shell, is found in all seas. Some species, as *P. costata,* reaching 6 in. in length, are used for food. *See also* Piddock. V. L. L.

**STONECHAT,** a small bird (5 in.) of the thrush family, *Saxicola torquata,* which, in many forms, inhabits the Old World from the British Isles to Japan and south to India and the Cape of Good Hope. It is allied to the wheatears and the true redstarts. The male is mainly chestnut pink below and dark brown above, with a black head and white markings on the neck and wings; the head and neck of the female are brown like the back. The stonechat, so called because of the similarity of its alarm note to the clicking together of two pebbles, lives in open, bushy country. It feeds chiefly upon insects and their larvae, and nests in low and preferably thorny shrubs. H. G. De.

**STONE, CLAY, AND GLASS INDUSTRIES.** An abundance of the necessary raw materials in most parts of the country has made the United States the world's foremost producer of stone, clay, and glass products.

**Evolution.** The stone, clay, and glass industries are one of the oldest major groups in the history of manufacturing. Their origin in many instances has been lost in antiquity. Products of glass were formed by Stone Age man from a volcanic ash known as obsidian. Obsidian is translucent in character, readily broken into sharp, elongated pieces which can be fashioned into objects of various kinds. More advanced cultures used obsidian in the manufacture of mirrors and jewelry. Products of stone and clay have similarly remote historical origins and have been found all over the world. Stone, clay, and glass products were identified as articles of commerce as early as the Bronze Age and continued to be an important phase of commercial and economic development in the history of mankind. More than many other industries, stone, clay, and glass manufactures resisted the introduction of modern manufacturing techniques and maintained for a relatively long period efficient but antiquated methods of manual production. For centuries there was little progress in the methods of manufacturing. The arts were passed down from generation to generation and often guarded with extreme jealousy by those well-versed in the production techniques. Almost every country in the world developed its own particular type of product, and such identifying names as Venetian glass, Dresden china and Bohemian ware are typical of the individual characteristics of stone, clay, and glass manufacturing. As a result, the volume of production remained small, and the output was limited largely to the needs of the communities where the products were sold. Until the 1870's, production methods had shown very little change, aside from certain refinements of existing techniques. In fact, not until the twentieth century did the stone, clay, and glass industries emerge from relative insignificance to major importance in manufacturing. There were greater and more important changes in the first quarter of the present century than in the thirty or forty preceding centuries.

**Development in the United States.** Although many of the basic techniques and processes of stone, clay, and glass manufacture were developed in Europe, it remained for the United States to introduce large-scale production and mechanization. Today this country is the undisputed leader in production. There are five basic reasons for its dominance. The first is the presence of large and favorably situated deposits of raw materials. These include materials principally derived from the earth in the form of stone, clay, sand, gypsum, and asbestos and, of lesser importance, barium, borax, feldspar, mica, silica, and talc. One or more of the foregoing can be found in almost any section of the country in sufficient quantities to make production possible. In the second place, there are adequate supplies of fuel and motive power. Perhaps one of the principal reasons for the slow development of the stone, clay, and glass industries in Europe has been the inadequacy of fuel. Large quantities of fuel are consumed in relation to the quantity of products produced. In the production of cement, for example, one-half ton of coal is consumed for every ton of cement produced. The United States is well supplied with coal and can supplement this fuel with oil and natural gas. Thirdly, there is an extensive domestic market, which was stimulated by a growing population and an excellent transportation system. Fourthly, the country has a large and sufficiently skilled labor force. Finally, the United States has led in the mechanization of production techniques. *See also* Engineering Materials; Glass. R. M.

**STONE CRAB,** a very thick-shelled true crab, *Menippe mercenaria,* occurring along the southeastern coasts of the United States and highly prized as an article of food. The stone crab of America lives in burrows just below low-tide line from North Carolina to Mexico and along the coast of Cuba. It attains a size of 5 in. across the back. Formerly found in abundance, this crab has been caught so extensively for food that it was threatened with extinction, and protective measures had to be taken. Since much of the choicest meat is contained in the larger claw, some fishermen have adopted the procedure of breaking off this claw and releasing the crab to grow a new one. In other parts of the world, decapod crustaceans belonging to different groups, notably the anomuran crabs related to the hermit crabs, are commonly referred to as stone crabs. F. A. C.

COURTESY OF THE U. S. FISH AND WILDLIFE SERVICE

*The stone crab,* Menippe mercenaria *of the family Xanthidae, is found in coastal waters of the southern United States.*

**STONECROP.** *See* SEDUM.

**STONE FLY,** the common name of members of the insect order Plecoptera. They have long antennae and a pair of short to long tail-like processes at the end of the abdomen. The wings have numerous cross veins; the front wings are narrow, with rather parallel sides; and the hind wings, which are about twice as wide, fold under the front ones when at rest. Many of the stone flies are very slender, and the wings may fold so as to cover the sides of the body. The nymphs are aquatic and most of them are predaceous upon other aquatic insects, crawling over stones, sand, and submerged branches in search of prey. A few kinds are herbivorous, feeding on aquatic plants. A large part of their diet consists of May flies, but stone flies in turn are an important fish food. They vary in size from less than ½ in. to over 1 in. C. H. Cu.

**STONEHAM** [sto′nəm], a town in northeastern Massachusetts, situated in Middlesex Co., 10 mi. north of Boston, of which it is a residential suburb. Founded in 1645, it was originally a part of Charlestown and for a while was called Charlestown End. In 1725 it was incorporated as a separate town. The town meeting administers the community. Within the town's limits is Spot Pond, a storage basin for the metropolitan water district, and more than 700 acres of the Middlesex Fells Reservation. The residents of Stoneham early developed small industries, such as shoemaking, in their own homes, and they were pioneers in the use of steam power and laborsaving machinery in shoemaking, including the heeling machine invented by John Hill in 1862. Shoes are a leading item of the factory output, which includes window shades, chemicals, drugs, upholstered furniture, and confectionery. The Boston and Maine Railroad supplies transportation. Pop. 1950, 13,229.

**STONEHENGE** [sto′nhɛnj], the most famous of prehistoric megalithic monuments. Stonehenge is situated on Salisbury Plain in southern England. At present visible are traces of an outer ditch, some outlying stones, an outer circle of trilithons, each consisting of two sarsen stone uprights with a lintel held in position by a tenon and mortise arrangement, an inner circle of monilithic bluestones from the Prescelly Hills of Wales, a U-shaped arrangement of five sarsen trilithons, and a similar setting of bluestone monoliths.

Excavation has revealed three concentric circles of holes in the chalk subsoil between the bank on the inner side of the ditch and the stone circles, an outer one noted by the early antiquary John Aubrey and two inner ones (Y & Z holes). It is evident that, like a cathedral, Stonehenge took shape over a long period of time. The first monument was a large earthwork (c. 1800 B.C.). About 150 years later large bluestone blocks, 40 tons or more in weight, were brought from Wales to construct two concentric circles of stones oriented so that the midsummer sun as it rose would shine upon a recumbent altarstone. The bluestones from Pembrokeshire, Wales, originally 82 of them, were probably dragged on sledges to the Welsh coast where boats carried them by sea and up the river Avon to the building site. A 70-ft.-wide, embanked avenue, first detected by air photography, approached the temple from the river, about 1½ mi. away. A third construction (c. 1500 B.C.) consisted of a circle of thirty uprights capped by stone lintels, surrounding a horseshoe of trilithons. The new stones were dragged from the Marlborough Downs 25 mi. away. A. H. Sw.

**STONE MOUNTAIN,** the name both of a dome-shaped granite mountain in De Kalb County, near Atlanta, Ga., and of an adjoining city with a population of 1,408. The mountain rises more than 650 ft. and covers an area of about 2 sq. mi. The northern slope rises as a sheer cliff for 300 ft. and then assumes a dome appearance with an almost naked rock surface, except for an occasional crevice with small trees and shrubs. The bulk which rises above the plain has been estimated to encompass seven and one-half billion cubic feet of granite. On the precipitous northern face of Stone Mountain, the Stone Mountain Memorial to the Confederacy is being carved. The plan calls for a huge relief of General Lee and other heroes followed by Confederate soldiers. The idea was conceived in 1916 by the sculptor Gutzon Borglum, who began to execute his design the following year. His design was 200 ft. high and 1,300 ft. long. In 1924 the head of Robert E. Lee was unveiled, but as a result of a disagreement between Borglum and members of the Stone Mountain Association, which was financing the project, Borglum was dismissed. In 1926 Henry Augustus Lukeman was engaged to complete the project. Lukeman destroyed Borglum's head of Lee, and executed one of his own. In 1929 Borglum was recalled, but the project has been suspended because of a lack of funds. P. H. N.

**STONE PLANTS,** also called stone-mimicry plants, a unique group of South African desert plants which closely

resemble the pebbles among which they grow. The small plant body is almost entirely hidden beneath the sandy or gravelly soil, the only part showing being one or two pairs of exceedingly fleshy leaves, which often assume the colors of nearby stones. Except when they bloom, they are scarcely distinguishable on the desert floor. The flowers, consisting of many narrow petals, often brightly colored and glistening in texture, are frequently larger than the rest of the plant. They belong to the same family as the fig-marigold, and include several distinct genera, among them *Mesembryanthemum,* most of which are in cultivation in the United States. They make interesting and satisfactory plants for indoor culture in a south window.

In these same genera, and in several others, are the windowed plants, which have a translucent membrane over the part of the leaf that is exposed. In the burning deserts of

COURTESY OF THE NEW YORK BOTANICAL GARDENS

*Stone plants of the South African desert*

South Africa, these plants grow completely submerged in the sand except for the tip of each windowed leaf. Through the "window" the sun's rays are filtered to the green tissues of the buried plant. A few windowed plants occur in other families. C. H. Wo.

**STONE ROLLER,** *Campostoma anomalum,* a small minnow, of the family Cyprinidae, adapted for life on the bottom of streams. Found in North America east of the Rocky Mountains, it is a unique minnow with a very long intestine coiled spirally about the air-bladder. An herbivorous form, it scrapes diatoms and other small material off stones, employing a cartilaginous pad on the inside of the lower lip as a scraper. Ordinarily it is a dull or brassy colored fish, but in early spring the males assume a bright orange nuptial coloration with a dark bar in the dorsal, anal, and caudal fins. Fairly large, sharp, breeding tubercles line the top of the head and back. The males gather in groups just above riffles and dig cup-shaped nests. Their tubercles help protect them from injury by the sand and gravel which they toss out of the nests by sideward motions of the head. The eyes of many stone rollers are destroyed when they are struck by the tubercles of a pugnacious neighbor. They reach a length of 6 to 8 in. and serve as natural forage for game fishes. E. C. R.

**STONEWORTS.** *See* ALGAE; PLANT SYSTEMATICS.

**STORAGE BATTERY, ELECTRICAL.** A storage battery is an electrochemical device capable of the following:

1. Accepting direct-current electrical energy (charging);
2. Retaining this energy in the form of chemical energy (charge retention);
3. Releasing its energy as direct-current electrical power on being connected to an external circuit (discharging); and
4. Repeatedly performing functions 1, 2 and 3 (cycling).

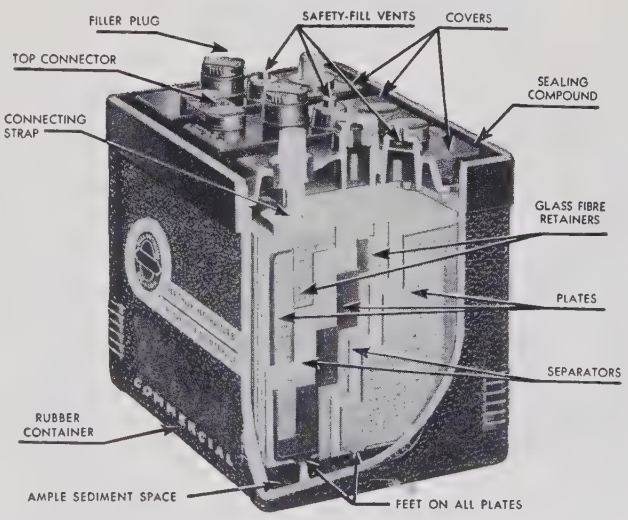
Storage batteries are also called secondary batteries, to distinguish them from primary batteries, which are not capable of Functions 1 and 4.

Storage batteries commonly used may be classified in either of two major categories: (a) lead-acid type; and (b) alkaline type.

## LEAD-ACID STORAGE BATTERIES

**Construction.** Lead-acid storage batteries are made up of one or more identical units called cells having a nominal potential of 2 volts each. Thus the ordinary 6-volt automobile battery has three cells connected in series.

*Plates.* Each cell consists essentially of electrodes of lead in two or more of its chemical forms in an acid electrolyte, or solution—usually dilute sulphuric acid. The electrodes are commonly referred to as positive plates and negative plates. These plates consist of a structural frame and electrical conductor called the grid, which is made of metallic lead alloy, and the active material of lead in other forms (chemical states), which fills the grid spaces and does the electro-chemical work required. The grid is cast from an alloy of lead, antimony (6 to 12 per cent in automotive practice), and minor fractional percentages of tin, bismuth, arsenic, and other elements. The active material in the positive plate is lead peroxide, $PbO_2$. Its physical form is that of a chocolate-brown, highly porous mass of self-bonded crystals that is readily permeated by the electrolyte. The negative-plate active material is a porous



COURTESY OF THE WILLARD STORAGE BATTERY CO.

*Cut-out view of one type of lead-acid storage battery, showing principal parts*

mass of finely divided self-bonded particles of metallic pure lead plus a minor portion of additives that have the function of maintaining the porosity of the negative active material as it goes through the process of being repeatedly charged and discharged during the life of the battery.

*Separators.* The plates are assembled by interleaving

alternate positive and negative plates together with separators that prevent their touching each other. These separators must be acid-resistant and readily permeable to electrolyte and electric current. This permeability must be of a microporous nature to prevent penetration by particles of active material that become loosened from the positive plate during the cycling life of the battery. Separators are usually flat on the side next to the negative plate and grooved or ribbed on the side bearing against the positive plate.

The most commonly used separator material is wood that has been chemically treated to remove much of the resin and acids. Certain kinds of cedar appear to have the best characteristics, closely followed by fir. Synthetic separators of microporous rubber are also widely used and are especially effective where the battery may encounter high climatic or charging-rate temperatures. Separators may be reinforced with an auxiliary sheet of porous material such as glass fiber or perforated rubber. This reinforcement is placed against the face of the positive plate and is an aid in restraining the shedding of active material during the life of the battery when the latter is subject to heavy cycling duty.

*ELECTROCHEMICAL ACTION IN A LEAD-ACID STORAGE BATTERY*

*(Spelling of "sulfate" and "sulfuric acid" is that preferred by the AABM.)*

COURTESY OF THE ASSOCIATION OF AMERICAN BATTERY MANUFACTURERS

**Chemistry of Cells.** The electrolyte (solution) of the lead-acid battery is usually dilute sulphuric acid ($H_2SO_4$), which will vary with the state of charge of the battery, being at a maximum when the battery is fully charged and at a minimum when it is completely discharged.

*Discharge Reactions.* The lead storage cell when fully charged consists of a lead (Pb) plate as the negative (cathode) terminal and a lead dioxide ($PbO_2$) plate as the positive (anode) terminal. Both plates are immersed in an electrolyte of sulphuric acid. During discharge, the active materials and electrolyte in the battery undergo a chemical change. The lead at the negative plate loses two electrons ($e$), whereas the lead dioxide at the positive plate gains two electrons. At the negative plate the reaction is:

$$Pb \rightarrow Pb^{++} + 2e$$
$$Pb^{++} + SO_4 \rightarrow PbSO_4 .$$

At the positive plate, the simultaneous reaction is:

$$PbO_2 + 2H^+ \rightarrow PbO + H_2O - 2e .$$

The lead monoxide (PbO) thus reacting with the sulphuric acids ($H_2SO_4$) produces the following result:

$$PbO + H_2SO_4 \rightarrow PbSO_4 + H_2O .$$

Thus, during the discharge both plates become covered with lead sulphate ($PbSO_4$). At the same time the specific gravity of the electrolyte is lowered because some of the sulphuric acid has been converted into water.

*Charge Reactions.* Upon charging, the original conditions of the battery are restored by passing through it a current in the direction opposite to that produced by the battery while it is in service; that is, the lead sulphate at the positive plate is restored to lead dioxide ($PbO_2$) and at the negative plate lead sulphate is restored to lead (Pb). Thus, at the negative plate the hydrogen ion gives up two electrons, resulting in the following reaction:

$$PbSO_4 + 2H^+ + 2e \rightarrow Pb + H_2SO_4 .$$

At the positive plate, the sulphate ion gives up two electrons and the reaction is:

$$PbSO_4 + SO_4^{=} - 2e \rightarrow Pb\,(SO_4)_2 .$$

Since plumbic sulphate $Pb\,(SO_4)_2$ is not stable in water, the final reaction is:

$$Pb(SO_4)_2 + 2H_2O \rightarrow PbO_2 + 2H_2SO_4 .$$

The charging reaction results in an increase in the specific gravity of the electrolyte. The cycle of charge and discharge may be repeated many times until some portion of the physical structure of the battery fails because of electrolysis of the metal or oxidation of the separator material. The majority of batteries have a specific gravity of about 1.280 when fully charged, but this may be varied between 1.225 in tropical climates and 1.300 in cold climates. The minimum specific gravity when the battery is discharged will vary between wide limits depending on the design of the battery. Generally speaking, a specific gravity of 1.150 indicates that the battery is discharged by 90 per cent or more.

*Efficiency.* The efficiency of a battery—that is, its ability to accept, store, and deliver energy—is markedly affected by change in temperature, as are most chemical and electrochemical reactions. Lowered temperature results in lowered efficiency. For example, an automobile battery is only 65 per cent as efficient at 32° F. as at 80° F., and only 40 per cent as efficient at 0° F. Increased viscosity in the engine oil as a result of cold weather adds to the load of starting in about the same ratio; thus 2½ times as much power is required at 0° F. as at 80° F.

The efficiency is also materially affected by the rate at which a battery is charged or discharged. It is most efficient when charged and discharged slowly. It is this characteristic which largely controls the design of a battery. If the unit is to be subject to low rates of charge and discharge over long periods, relatively few and compara-

tively thick plates may be used. If the requirements call for rapid charge and high rates of discharge as in engine starting, a large number of thin plates must be used. Hence, the plate surface governs the rate at which a lead-acid storage battery will perform its electrical and electrochemical functions.

### ALKALINE STORAGE BATTERIES

In alkaline batteries, the electrolyte is basic rather than an acid. The most familiar alkaline storage battery is the Edison cell type, often referred to as the nickel-iron-alkaline type of cell. Another alkaline battery is the nickel-cadmium type. The nickel-iron and the nickel-cadmium are more common in Europe.

The electrolyte is an aqueous solution of potassium and lithium hydroxide and does not at any stage cause a disintegration or solution of the active materials. Since only a relatively small quantity of the potassium and lithium hydroxides is absorbed by the higher nickel oxide electrode, the composition of the electrolyte does not vary appreciably throughout the cycle of charge and discharge. The conductivity and specific gravity of the electrolyte are therefore practically constant. The lithium hydroxide permits of greater utilization of the active materials in the higher nickel oxide electrode, and its use results in greater capacity and increased life. It is therefore an indispensable component of the electrolyte.

**Construction.** The active materials are packed in perforated nickeled-steel tubes or pockets to form the plates. The positive plate is usually in the form of a number of vertical tubes placed side by side. Flake nickel is tamped in alternate layers with the nickel hydrate in the positive tube to improve its electrical characteristics. The tubes are reinforced by eight encircling seamless-steel rings mounted at equally spaced intervals on the grid. The negative plate is similar except that finely divided oxide of iron is used as the active material and is contained in rectangular perforated pockets instead of tubes.

*Group Assembly.* The positive and negative plates are assembled into positive and negative groups. This is done by passing a connecting rod through holes at the top of the grids. Steel washers are used to obtain proper spacing, the middle spacer being the base of the pole piece. A lock washer and nut are drawn up tight at each end of the connecting rod, binding the plate group firmly together. All washers, nuts, connecting rods, and terminal posts, like the plates, are of nickeled steel.

*Element Assembly.* The plate groups are assembled into complete elements by intermeshing the plates. The negative group always contains one more plate than the positive, so that both outside plates are always negative. Insulation between the alternate positive and negative plates is accomplished by means of vertical hard rubber pins running their entire length. Rubber sheets insulate the outside negatives from the sides of the container, while the edges of the plates are insulated from the bottom and the other sides of the container by means of hard-rubber frames. These frames also serve the purpose of separating the grids and holding the plates in correct alignment, and are so designed as to permit free circulation of the electrolyte.

*Container.* Potassium hydroxide, the electrolyte, does not attack steel; and this fact is taken advantage of in the nickel-iron-alkaline cell in order to obtain the strength and durability of steel in the container as well as in the elements. The container, like the elements, is made of nickeled steel with all joints welded.

The cell cover, also of nickeled steel, is welded in place. Soft-rubber bushings, expanded by steel rings and hard-rubber screw washers, or gland caps, insulate the pole pieces where they project through the cover, and provide an airtight and liquid-tight packing. All cells are coated with a heavy insulating paint, after which a protective film of rosin petroleum jelly is applied to the cell tops. Connectors are secured by tightening down nuts and are removed by means of a small jack after loosening the nut.

*Battery Assembly.* Nickel-iron-alkaline cells are assembled into batteries in hardwood trays. Steel suspension bosses, previously spot-welded to the sides of the cell containers, fit into hard-rubber buttons recessed in the tray slats. This assembly supports each cell in place and insulates it from the tray and adjacent cells.

**Chemistry of Cells.** The active materials of storage cells do not store electricity as such but are so chemically and physically changed by applied electrical energy as to be capable of producing electrical energy through conversion to their former state.

*Charge Reactions.* The chemical changes that occur when the nickel-iron-alkaline cell is charged may be represented by chemical equations. The potassium hydroxide ($2KOH$) electrolyte ionizes into $2K^+$ and $2OH^-$. The chemical reactions resulting at the negative plate consisting of ferrous oxide ($FeO$) and at the positive plate consisting of nickel oxide ($NiO$) are respectively as follows:

$$FeO + H_2O + 2K^+ \rightarrow Fe + 2KOH + 2e$$

$$2KOH \xrightarrow{\text{ionizing}} 2K^+ + 2OH^-$$

$$NiO + 2OH^- + H_2O \rightarrow NiO_2 + 2H_2O - 2e.$$

*Discharge Reactions.* The chemical changes that occur when the cell is discharged, at the negative and positive plates, are, respectively, as follows:

$$Fe + 2OH^- \rightarrow FeO + H_2O - 2e$$

$$2KOH \xrightarrow{\text{ionizing}} 2K^+ + 2OH^-$$

$$NiO_2 + H_2O + 2K^+ \rightarrow NiO + 2KOH + 2e.$$

**Operating Characteristics.** The average discharge voltage per cell at the normal 5-hr. discharge rate is approximately 1.20 as compared with 2 volts for the lead-acid battery, so that more Edison cells than lead cells are needed to produce a battery of the same voltage. The relative over-all size of the batteries is approximately the same, however, and on an equivalent kilowatt-hour basis the Edison battery is lighter.

The state of charge of this type of cell must be determined by electrical test, i.e., by voltage under charge or discharge. The charge cannot be determined by hydrometer reading, since the electrolyte specific gravity does not vary with state of charge. *See also* ELECTROCHEMISTRY; ELECTROLYTES; MOTOR VEHICLES. L. E. W.

**STORAX** [sto′ræks], a balsam, semiliquid, grayish-brown in color, having a characteristic odor and taste, obtained from the trunk of *Liquidambar orientalis,* a native of Asia Minor, and known in commerce as Levant, or liquid, storax. It is used in the treatment of scabies and of other parasitic skin diseases. It is also used in perfumery, and as imbedding material in microscopy. A fragrant resin derived

from the storax tree, native to the Mediterranean region, was once much used for incense and perfume. *See also* LIQUIDAMBAR. J. A. Bo.

**STORK,** any one of a number of species of very large wading birds, allied to the herons, which form the family Ciconiidae. They are found in temperate and tropical regions throughout the world, excepting that of the oceanic islands. They are characterized by long legs, a long neck, and a long,

JOSEPH ADAMS FROM FREDERICK LEWIS

*MALAY STORKS*

heavy bill; their plumage may be mainly gray, metallic-glossed black, or black and white, but a few possess patches of brighter colors. Storks usually inhabit open plains or marshy ground, where they feed upon large insects, mollusks, amphibians, reptiles, and other forms of animal life. They build massive nests of sticks on cliffs, lofty trees, or even occupied houses. They are voiceless, but during the breeding season indulge in grotesque courtship dances, which are accompanied by loud noises made by clattering together the upper and lower halves of the bill. The white stork of the Old World, *Ciconia ciconia,* is conspicuous in many of the towns and has entered largely into popular proverbs, tales, and fables. The only stork occurring in the United States, *Mycteria americana,* known as the wood ibis, is locally common in the southern parts of the country from Florida to California. H. G. De.

**STORM, THEODOR** [shtɔ'rm] (1817-1888), German poet and writer of prose fiction, was born at Husum, in Schleswig-Holstein, on Sept. 14, 1817, of a well-established, middle-class family. He attended the universities of Kiel and Berlin and began his literary career in 1843 when with Tycho and Theodor Mommsen he published *Liederbuch dreier Freunde,* which contains his earliest poetry. In 1843 Storm established a law practice in Husum, and in his leisure time he began to write short tales. During the struggle between the Danes and the German element for control of Schleswig-Holstein, Storm, who was outspoken in the German cause, lived in Germany from 1853 to 1864. Upon the incorporation of Schleswig-Holstein into Prussia, he returned to Husum and to a position of prominence in the local government. His wife, Konstanze Esmarch, died in 1865, leaving him with seven children, and shortly afterward he married Dorothea Jensen, a childhood sweetheart. During the last part of his life he carried on an active correspondence with Edward Mörike, Paul von Heyse, and other prominent writers of his day. In 1880 he retired from public life to the nearby town of Hademarschen, and there he died on July 4, 1888.

Storm's stories (*Novellen*) usually express a somber, reflective mood and bear evidence of the author's lyric gifts. They are filled with descriptions of the coast and moorland of his native province, to which he always remained closely attached, and with memories of the old city of Husum. In the genre of the *Novelle,* Storm strove toward perfection of form, and his work shows a clear development from beginning to end. The perennially popular *Immensee* (1852) and the later *St. Jürgen* (1867) are representative of his early sentimental stories, in which a note of resignation is usually a prominent feature. In the next period he showed more variety, as in *Viola Tricolor* (1873) a psychological study of a second marriage, *Pole Poppenspäler* (1874), a charming children's story, and *Psyche* (1875), a sunny tale of a young artist's love. Finally Storm turned to more realistic, historical tales, written for the most part in the slightly archaic style of old chronicles; among these are *Aquis Submersus* (1877), *Eekenhof* (1878), *Zur Chronik von Grieshuus* (1884), and, the culmination of all Storm's stories, *Der Schimmelreiter* (1888). Storm's reputation as a lyric poet was established by the publication in 1852 of a book of verse in the Romantic vein. J. F. McM.

**STORM LAKE,** a city and summer resort in northwestern Iowa, the county seat of Buena Vista Co., situated on the lake of the same name, about 60 mi. east of Sioux City. Corn, oats, and livestock are raised in the region. The community has the mayor-council form of government. Storm Lake is the seat of Buena Vista College. Transportation is supplied by the Illinois Central and the Chicago, Milwaukee, St. Paul and Pacific railroads. Local industries include meat packing, hog and poultry processing, canning, and the manufacture of butter, medical appliances, and silo tanks. Pop. 1950, 6,954.

**STORY, JOSEPH** (1779-1845), American jurist, was born at Marblehead, Mass., Sept. 18, 1779, and was educated at Harvard University where he graduated in 1798. Afterwards he studied law at Marblehead and at Salem, where he was admitted to the bar in 1801. He was the representative of Salem in the Massachusetts legislature from 1805 to 1807. In 1808 Story was elected to Congress, and served one term there, until March 1809. He was speaker of the Massachusetts legislature in 1811, and in November of the same year was appointed by President James Madison as an associate justice of the United States Supreme Court. During the War of 1812 he was responsible for many important decisions on the subject of maritime prizes. In 1829, Story was appointed the first Dane professor of law at Harvard University, a position which he retained for the rest of his life, while remaining a justice of the Supreme Court. Among his books are *Commentaries on the Law of Bailments* (1832), *Commentaries on the Constitution of the United States* (3 vols., 1833), *Commentaries on Equity Jurisprudence* (2 vols., 1836), *Law of Agency* (1839), *Law of Partnership* (1841), and *Law of Bills of Exchange* (1843). Story was a determined opponent of slavery and was very unpopular in those states where it prevailed. As a justice of the Supreme Court he was largely responsible for all subsequent American equity jurisprudence. He died at Cambridge, Mass., Sept. 10, 1845. R. T.

**STORY, WILLIAM WETMORE** (1819-1895), American sculptor, poet, and author, son of the eminent jurist, Joseph Story, was born in Salem, Mass., Feb. 12, 1819. He graduated from Harvard in 1838, later went to Italy to study art, and settled permanently in Rome about 1848. His reputation as a sculptor, which was high during his lifetime, has declined in the twentieth century. His best known work is a statue of Cleopatra first exhibited in London in 1862. In general, his works are pervaded by a literalness and theatricalism more appropriate to writing than to sculpture. His career is recorded by Henry James in *William Wetmore Story and His Friends.* Story died in Vallombrosa, Italy, Oct. 7, 1895. A. TenE. G.

**STOSS, VEIT** [shto's] (c. 1440-1533), sculptor, was born in obscure circumstances, his birthplace being claimed by both Poland and Germany. He worked in Kraków from 1477 to 1496, where he was highly regarded, and where he left one of his greatest works, the High Altar of the Church of Our Lady (1477-1489). From 1496 until his death in 1533, Stoss worked in Nürnberg, weathering a period of disgrace and legal prosecution arising out of a confessed dishonesty. A son, Stanislas, was left in charge of the workshop established in Kraków.

Though Stoss's origin is controversial, his style and the construction of his large religious works correspond closely to the late Gothic types of southern Germany. Brilliantly realistic in detail, these compositions have a general effect of artificial intensity due to the strained postures of the figures and the overelaborate folds of the heavy drapery. The folds, in fact, often become so complex as to develop a fascination and a sense of drama all their own.

The outstanding work by Stoss in Nürnberg is the great Rosary, containing a representation of the Annunciation (1517-1518), which hangs over the choir in the Church of St. Lawrence. Like the Altar in Kraków, it is carved in wood and preserves the elaborate polychromy of late Gothic work. Stoss also did some stone carving, notably the tombs of two Polish archbishops in the Cathedral of Gnesen. L. R.

**STOUGHTON** [sto'tən], a town in east central Massachusetts, which includes the village of Stoughton and several other villages, situated in Norfolk Co. about 16 mi. south of Boston, that is in an area marked principally by truck gardening. Founded about 1713 and originally a part of Dorchester, Stoughton was incorporated as a town in 1743. The local government is the council-manager type. The town was named in honor of a colonial governor. During the Revolution it was an important supply center for colonial troops. Transportation is provided by the New York, New Haven and Hartford Railroad. Manufactures include woolen knit goods, shoes, shoe lasts and shoe trees, rubber specialties, elastic webbing, raincoats, and confectionery. Pop. 1950, 11,146.

**STOW, JOHN** [sto'] (1525-1605), English antiquary and historian, at first followed the trade of tailor in London, but after 1560 devoted his entire time to antiquarian research. He edited the works of Chaucer in 1561, and published *A Summarie of Englyshe Chronicles* in 1565, and *The Annales of England* in 1592. Stow's principal work, *A Survay of London* (1598), is a description of the city and its customs in Shakespeare's time. His accurate first-hand observation and careful scrutiny of documentary materials make him the most dependable of Elizabethan historians. He died in London, Apr. 5, 1605. W. R.

**STOWE, HARRIET ELIZABETH BEECHER** [sto'] (1811-1896), American author, was born June 14, 1811, in Litchfield, Conn. Daughter of the staunch Calvinist conservative, the Reverend Lyman Beecher, and sister of five clergymen, among them the famous pulpit orator, Henry Ward Beecher, she grew up and was educated in the waning Puritan atmosphere of Connecticut. In 1832 she moved to Cincinnati, where her father had been made president of Lane Theological Seminary. Here she gained her first direct

*HARRIET BEECHER STOWE*

BROWN BROTHERS

knowledge of slavery. Here also, in 1836, she married Professor Calvin E. Stowe, who had encouraged her writing, and by 1850, when her husband accepted a position at Bowdoin College in Maine, she was the mother of seven children. Back in the New England atmosphere of rising religious abolitionism, she poured her own indignation over the Fugitive Slave Law into *Uncle Tom's Cabin* (1851-1852), the novel which brought her fame. Despite its artistic faults and its unrelieved sentiment, it was a great humanitarian document, and its world-wide success made it one of the most potent pieces of propaganda ever written. A second antislavery novel, *Dred; a Tale of the Great Dismal Swamp* (1856), was a sounder piece of writing, but never became as popular. Mrs. Stowe's later fiction was great in volume but uneven in quality, her best work lying in her stories of the local life of her own Puritan New England. *The Minister's Wooing* (1859), *The Pearl of Orr's Island* (1862), and *Oldtown Folks* (1869) are acute psychological and spiritual studies of real people; only occasionally are they marred by the author's characteristic fault of using a story to preach an abstract principle. Mrs. Stowe died July 1, 1896, in Hartford, Connecticut. *See also* UNCLE TOM'S CABIN. E. C. Sh.

**STOWE,** a residential township in southwestern Pennsylvania, situated in Allegheny Co., on the Ohio River and on the northwestern outskirts of Pittsburgh, of which it is a suburb. The government is the mayor-councilmanic type. The principal local industry is the manufacture of railroad equipment. Pop. 1950, 12,210.

**STRABISMUS.** *See* EYE (*Eye Diseases; Eye Surgery*).

**STRACHEY, GILES LYTTON** [stre'tshi] (1880-1932), English historian and essayist, was born in London, Mar. 1, 1880, of parents who had distinguished literary and political

connections. Strachey was educated privately and at Trinity College, Cambridge. He began early to publish in literary magazines, and, after his reputation was established, he was a member of the celebrated Bloomsbury group, along with Clive Bell, E. M. Forster, Virginia Woolf, and others. He did not marry and lived with his mother until her death. He himself died on Jan. 21, 1932.

Strachey's literary career was remarkably homogeneous, and it may be said that the book that first brought him to notice, *Eminent Victorians* (1918), set the tone that was to be characteristic of all his later work. It contained studies of Florence Nightingale, Cardinal Manning, and other prominent Victorian persons, the scholarly foundation of the work being concealed by a neat, malicious style which, critics observed, is found more often in psychological or satirical fiction than in ordinary biographical writing. His two full-length studies, *Queen Victoria* (1921) and *Elizabeth and Essex* (1928), established Strachey as a master of his chosen method. *Queen Victoria* and *Eminent Victorians* had a wide popularity for another reason: they attacked an age against which many readers in the 1920's were already in revolt. This attitude and the Strachey technique set a style in biographical writing that tended to degenerate in less skillful hands, the many "debunking" biographies that resulted from this imitation seldom exhibiting the penetration, the wit, the careful choice of detail, and the precision of statement that characterize Strachey's work at its best. H. H. Wa.

**STRADIVARI, ANTONIO** [strɑ′divɑ′ri] (c. 1644-1737), the most celebrated of Italian violinmakers, was born probably in 1644. The exact date and place of his birth are unknown, but the first documentary evidence of his residence in Cremona, the city in which he lived and worked throughout his life, is furnished by one of his violin labels dated 1666. It is this label which also furnishes proof that Stradivari was apprenticed to Nicolò Amati. He died at Cremona, Dec. 18, 1737.

Nearly all of Stradivari's ninety-three years were spent in perfecting his art and in producing the marvelous instruments which were to give his name undying fame. The various periods of his work represent stages in his breaking away from Amati's influence and his search for a type of violin which would afford more breadth of resonance and power of tone. He adhered to the smaller type of instrument until 1684 when he definitely began to turn to larger instruments. His typical "long" pattern measures 14 5/16 in. in length, an increase of 6/16 in. over Amati's pattern. A reduction in the over-all length to about 14 in., with a broadening and arching of the instrument, produced a model of unsurpassable symmetry and beauty. To this later period also belong the finest of his violoncellos.

Stradivari made over a thousand violins, violas, and violoncellos; some six hundred are known to survive. Some of the more famous of the violins are the "Betts," now in the Library of Congress (1704), the "Viotti" (1709), the "Alard" (1715), and the "Messiah" (1716).

Although the Stradivari label is a distinctive one, bearing a Maltese cross and the initials A. S. enclosed within a double circle, there are many thousands of forgeries and imitations containing a reproduction of this label, and only an expert, by personally examining and playing on an instrument bearing a Stradivari label, can say whether it is genuine or false. P. G. G.

**STRADONITZ, FREDRICH AUGUST KEKULE VON.** *See* KEKULE VON STRADONITZ, FREDRICH AUGUST.

**STRAFFORD, EARL OF (THOMAS WENTWORTH)** [stræ′fərd] (1593-1641), English statesman, was born in London, Apr. 13, 1593. Educated at St. John's College, Cambridge, he was admitted to the Inner Temple and during 1612 and 1613 he traveled in Europe. He sat in the parliaments of 1614 and 1621, in the latter giving general support to the policy of King James I. In the parliaments of 1624 and 1625 he showed himself to be against Buckingham's policy of a war with Spain. He made a great enough impression for Charles I to appoint him sheriff in order to keep him out of the Parliament in 1626. It was the King's misfortune not to recognize that Wentworth was an honest critic and not a convinced opponent. In 1627 he was imprisoned for refusing to pay a forced loan which he considered to be illegal; and in the Parliament of 1628 he emerged as one of the leaders of the opposition striving to draw up and obtain the King's consent to the Petition of Right. Throughout Wentworth had been moderate; he had no sympathy with the extreme parliamentarians, who supported Sir John Eliot; he now believed that the King's power had been satisfactorily curbed and that further restrictions would lead to inefficiency in government. Therefore he went over to the King's side, and in December 1628 he was created Viscount Wentworth, and made president of the Council of the North. In 1632 he was appointed Lord Deputy of Ireland and set to work to carry out some much-needed reforms. He got rid of many incompetent officials; he encouraged economic development; and he raised an army paid for by the Irish parliament. His policy of "Thorough" was arbitrary, but aimed at bringing real benefit to a country where conditions had hitherto been chaotic, and where great officials had been tyrannous and corrupt. Wentworth returned to England in September 1639, became the King's chief adviser, and was made Baron Raby and Earl of Strafford in January 1640. On his return from a successful trip to Ireland to enlist aid for the King in England's coming war with Scotland, he found Parliament unwilling to grant the subsidy for the war that the King asked. After Strafford had persuaded Charles to modify his demands, Parliament insisted on peace, Charles reiterated his earlier demands, and Parliament was dissolved. Then the privy council advised that only a defensive war be waged, to which Strafford was diametrically opposed. On the assembling of the Long Parliament in November, Charles ordered Strafford to London, where he was impeached, Parliament being of the opinion that his death was essential to the liberties of the kingdom as part of the constitutional question of the administration leader's responsibility to the nation. Strafford was sent to the Tower on November 25 and executed on May 12, 1641. E. R. A.

**STRAIT OF MAGELLAN.** *See* MAGELLAN, STRAIT OF.

**STRAITS QUESTION,** an issue of international politics concerning the control of the Bosporus, the Sea of Marmara, and the Dardanelles. These Turkish Straits are of great commercial and strategic importance as providing the only means of egress from the Black Sea, and the question of their control is one of the oldest and most continuous problems in European history.

Since the signing of the Treaty of Kuchuk-Kainardji between the Ottoman Empire and Russia, on July 10, 1774, the principle of freedom of passage for merchant ships through the straits has been generally established, and the conventions of 1840, 1841, 1856, 1871, and 1878 still further specified the international character of this waterway. After the defeat of Turkey in World War I, the straits were opened to navi-

gation of every kind and were placed under an international commission until 1922. In 1923, by the Convention of Lausanne, international control was reduced, a portion of Turkish sovereignty was restored, the straits were demilitarized for 30 mi. inland, and a French, English, and Italian surveillance commission was established. This convention was modified in 1936 by the Montreux Convention, effective for twenty years; Turkey was permitted to remilitarize the area and was given complete control over the passage of shipping through the straits in time of war, but otherwise the principle of freedom of passage for merchant vessels was confirmed.

During World War II, Turkey was put under great diplomatic pressure because of the strategic importance of the straits both to Germany and to Western Allies. In 1941 she concluded a treaty of friendship with Germany which isolated the Soviet Union from Allied aid by way of the Black Sea, but Stalin's personal pledge not to occupy the Dardanelles and Allied economic aid and pledges of assistance in case Turkey were attacked prevented Germany from exploiting her diplomatic advantage still further and flanking the Soviet Union on the south through Turkey.

After the war an agreement was reached in Potsdam in 1945 to revise the Montreux Convention, but no immediate action was taken. It was decided, however, that the revision should be based on the principles that the straits should remain open to all merchant vessels and to the warships of Black Sea powers; that, except for a limited tonnage in time of peace, passage through the straits should be denied to the warships of non-Black Sea powers, except with the consent of those powers or except when acting under the authority of the United Nations; and that certain other changes, such as the substitution of the United States for Japan as a signatory, should be made in the Montreux Convention. This plan was accepted by Turkey as a basis for agreement and further discussion. S. C. M.

**STRALSUND** [shtrɑ'lzʊnt], a seaport in the former state of Mecklenburg, in northeast Germany, located 44 mi. northeast of Rostock on the Baltic Sea. The old city occupies a small triangular island joined to the mainland by moles at the angles. Thus it lies on the west coast of Strela Sound, which separates the Baltic island of Rügen from the mainland. Founded in 1209, Stralsund soon became a leading Hanseatic city. In 1628 during the Thirty Years' War, Albrecht von Wallenstein, in the service of the Holy Roman Emperor Ferdinand II, laid siege to the city of Stralsund for eleven weeks before he was forced to withdraw his troops without capturing the city. It belonged to Sweden from 1648 to 1807 and became Prussian in 1815. The town has a distinctly medieval aspect with many houses having high gables toward the streets. Noteworthy edifices, dating partly from the thirteenth century, include the brick Gothic town hall, and the churches of St. Nicholas, St. Mary, and St. James. The city is connected with Rügen Island by a railroad and highway causeway, over which moves rail traffic for Denmark. There is trade in fish, grain, and lumber, and manufactured products include beer, liquors, smoked fish, beet sugar, varnish, playing cards, and boats. Pop. 1939, 52,931. C. C. H.

**STRANGE CASE OF DR. JEKYLL AND MR. HYDE, THE** [jɛ'kɪl], a work of fiction by Robert Louis Stevenson, first published in 1886, which tells a story of the duality of the individual character, of the potentialities for both good and evil in one man. Dr. Henry Jekyll, an eminent London physician known for his upright character, develops a drug which changes him into the deformed, morally hideous, and wholly evil Edward Hyde. As Hyde, he roams the London streets at night, brutally injures a child, and later murders an aged member of Parliament. When the drug fails, after frequent use, to restore him to his better character, he kills himself, leaving with his lawyer, Mr. Utterson, a letter that tells the whole story. J. P. Wo.

**STRAPAROLA, GIOVANNI FRANCESCO** [strɑ'-pɑrɔ'lɑ] (d. c. 1557), Italian author, was born at Caravaggio late in the fifteenth century. The first part of his collection of tales, *Le piacevoli notti* ("The Entertaining Nights"), was published at Venice in 1550, a second part appeared in 1553, and he died sometime after 1557.

Using as the framework of his story the fiction that a company of ladies and gentlemen have gathered to pass the last thirteen nights of carnival listening to songs, stories, and riddles, Straparola relates the seventy-five tales told and the seventy-three riddles propounded. He was markedly original in venturing to introduce into the collection fables and fairy tales in which there are fantastic and supernatural elements, a type of narrative theretofore considered to appeal only to the lowest social classes and not to those who could read and afford books. The story of Puss in Boots, which appears for the first time in European literature in *Le piacevoli notti,* is the most familiar example of this type of tale in Straparola. The majority of his tales, however, deal with the erotic and satirical subjects usual in the collections of the age, and most of these are patent and often unskillful imitations of earlier works.

Extremely popular in sixteenth-century Italy and in France, where it was translated soon after publication, Straparola's work has had a wide influence in the field of the fairy tale. G. R. S.

**STRASBOURG** (*Ger.* **STRASSBURG**) [stra'sbu'r, shtrɑ'sbʊrχ], a river port, industrial center, and fortified frontier garrison, capital of the department of Bas-Rhin in the Alsace-Lorraine region of northeastern France, situated 240 mi. east of Paris. It spreads over a low-lying plain from both banks of the Ill River, just west of its confluence with the Rhine, at the terminus of canals connecting the Rhine with the Marne and the Rhône.

The Romans established on the island in the Ill, which is now the heart of the city, a fortified camp, Argentoratum. This developed as a center of river-boat and wagon traffic, known to the Teutonic tribesmen of the vicinity, the Alemanni, as Strataburgum (city of roads). In 843, when the empire of Charlemagne was divided, the city became part of the realm inherited by Lothaire and in 923 gave its allegiance, along with the rest of the territory ruled by the Dukes of Lorraine, to the German kingdom of the Holy Roman Empire. After a long struggle between the ruling bishop and the citizens, and as a result of the battle of Oberhausbergen in 1262, Strasbourg became a free imperial city. In 1381 Strasbourg joined the Städtebund, the league of Swabian towns. Its reputation as an intellectual center grew, following the development here of printing by Gutenberg in the first half of the fifteenth century and the foundation of a university in 1566. During the French Revolution, although it was here that Rouget de Lisle composed the *Marseillaise,* it was deprived of its rights as a free city because of its pro-German sentiment. The Germans captured it during the Franco-Prussian War, after a bombardment lasting from Aug. 13 to Sept. 27, 1870. Under German rule the city was much enlarged; suburbs were built and a port

was created. French troops re-entered it on Nov. 22, 1918. Occupied by the Germans again throughout World War II, it was recaptured Nov. 27, 1944, by the French.

The ancient part of the city, on the island embraced by the arms of the Ill, is distinguished for its picturesque old frame houses with steeply peaked roofs and ornamented façades. There are many historic churches dating from the thirteenth and fourteenth centuries. It has been a bishopric since the fourth century.

The port of Strasbourg, first developed by the Germans beginning in 1901 and enlarged by the French since 1918, with its numerous basins, docks, and warehouses, is one of the busiest French ports. The local industries include spinning and weaving, grain milling, brewing, distilling, cabinetmaking, automobile manufacture, tobacco processing, and production of chocolate and bakery goods. An important enterprise is the fattening of geese for the distinctive Strasbourg specialty, *pâté de foie gras*. Pop. 1954, 200,921.

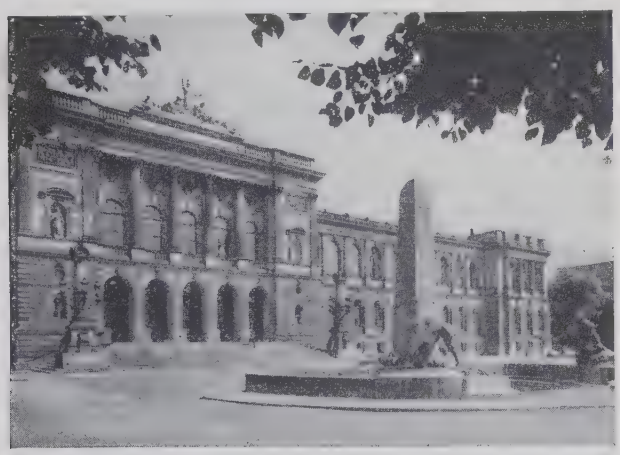
**STRASBOURG, UNIVERSITY OF,** at Strasbourg, France. Its history dates from 1538, when the humanist Johannes Sturm was called by the city of Strasbourg to



YVON

*The University of Strasbourg, founded in 1538, at Strasbourg in northeastern France*

establish a gymnasium by combining three existing high schools. Law, medicine, science, and letters were the first subjects taught. By 1566 this gymnasium had developed into an academy, and in 1621 it became a university with faculties of medicine, science, letters, and theology. Louis XIV confirmed the status of the university in 1697. The university was suppressed during the French Revolution and reopened in 1808. The university was inaugurated as Kaiser Wilhelm Universität on May 1, 1872, after Strasbourg had passed to the Germans at the end of the Franco-Prussian War. Taken by the French again, the university was reorganized and reopened on Nov. 22, 1919. It was removed to Clermont-Ferrand in 1939 at the beginning of World War II, and in 1945 was re-established at Strasbourg.

The university's present faculties teach in the departments of Catholic theology, Protestant theology, law, medicine, science, pharmacy, letters, and political studies. The faculty in 1948 numbered 250 and the student enrollment was 7,128. The library contains approximately 1,500,000 volumes.

A. L. H.-Q.

**STRASBOURG CATHEDRAL,** the Cathedral of Notre Dame in the city of Strasbourg, built of red sandstone, principally in Gothic style, with some Romanesque features. It is noted for its 464-ft. spire, one of the tallest in Europe. Its construction was begun in 1017; but of the present church, only part of the crypt dates to the time of Clovis. The choir, dating from the eleventh and twelfth centuries, is Romanesque; the apse is transitional in style; the nave, reconstructed between 1250 and 1275, is pure French Gothic. The elaborate west façade, celebrated for its wealth of sculpture, was begun in 1270; the tracery spire, which rises from the northern tower, designed by Johann and Jean Hültz of Cologne, was completed in 1439. Its magnificent rose window, 50 ft. in diameter, was designed by Erwin von Steinbach. This and the other windows are notable for their screens of double tracery. On the Romanesque south portal are fine sculptures. The interior is notable for its richly sculptured pulpit, dating from 1486, and for its stained glass.

**STRASSBURG.** *See* STRASBOURG.

**STRATEGY, MILITARY.** *See* MILITARY STRATEGY AND TACTICS.

**STRATFORD,** a city and the county town of Perth Co., Ontario, Canada, on the Avon River, 80 mi. west of Toronto, and 105 mi. northwest of Buffalo, N.Y. It is on Provincial Highways 7 and 8, and is an important divisional point for the Canadian National Railways. Surveyed by the Canada Company in 1834, it became a town in 1858 and was incorporated as a city in 1884. Its early development was as a supply center for Perth County, but in 1870 it obtained its first large-scale industry in the form of the railway shops, which continue to be a leading activity. Furniture factories, textile mills, packing plants, iron and brass foundries, flour mills, and dairy plants are important. A provincial normal school is located there. During World War II it was the site of a training camp for a Netherlands fighting force. Pop. 1951, 18,785.

D. F. P.

**STRATFORD,** a town and summer resort in southwestern Connecticut, situated in Fairfield Co., 3½ mi. east of Bridgeport, on Long Island Sound, at the mouth of the Housatonic River, in a general farming area. Stratford was founded in 1639 and was named after the English town Stratford-on-Avon. The government of the town is the council-manager type. Stratford in its early days was renowned for its shipbuilding and its oyster fisheries. A feature of historic interest is the David Judson House, built in 1723. Transportation is provided by the New York, New Haven and Hartford Railroad. Although Stratford is primarily a residential town, there are local manufactures of aircraft, machinery, brake linings, roofing, and hardware. Pop. 1950, 33,428.

**STRATFORD-ON-AVON,** a municipal borough in Warwickshire, England, situated on the west bank of the Avon River, 85 mi. northwest of London. It is famous as the birthplace and residence of William Shakespeare. Relics indicate that it was probably inhabited by Celtic tribes and later by Romans and Saxons. It received its first charter from Edward VI in 1553; others were granted in 1611, 1664, and 1674. The house where Shakespeare was born has been national property since 1847. It is a one-story, gabled, wooden structure, originally divided into two sections, the west part, which was the dwelling, and the east part, which was the workshop of John Shakespeare, William's father. A room in the west part has been indicated as the birthplace of the poet, although there is no evidence to substantiate the claim. New Place, bought by Shakespeare in 1597 and after his death

the residence of Thomas Nash and his wife, Shakespeare's granddaughter, was torn down in 1759. Its site was purchased by popular subscription in 1876. Shakespeare and his wife, Anne Hathaway, are buried near the chancel of Trinity Church. Of additional interest are Guild Hall, nearby, where the poet attended grammar school, his mother's cottage at Wilmcote, and Anne Hathaway's cottage at Shottery, a mile away. The Harvard House, built in 1596, and the home of the mother of John Harvard, was presented to Harvard University in 1909 by Mrs. Edward Morris. The sixteenth-century appearance of the town has been restored to represent Stratford-on-Avon as Shakespeare knew it. The older Shakespeare Memorial Theatre, built in 1877, was burned in 1926, and the new Memorial Theatre, built by popular subscription, was opened in 1932. The majority of the plays presented during the annual theatrical season in the Memorial Theatre are those written by the famous bard. The community is one of the most popular tourist spots in England. Agricultural trade and brewing comprise the principal industries. Pop. 1952, 14,610. A. W.

**STRATHCONA AND MOUNT ROYAL, BARON.** *See* SMITH, DONALD ALEXANDER.

**STRATHROY** [strathrɔi′], a town in Middlesex Co., Ontario, Canada, 22 mi. west of London, on the Canadian National Railways and Provincial Highway 22. Incorporated as a town in 1871, it is in the center of a fertile agricultural area, noted for its purebred cattle, registered seed grain, nursery stock, and tobacco farming. Textiles and furniture are manufactured in the town. Pop. 1951, 3,708. D. F. P.

**STRATHSPEY** [strathspe′; stra′thspe], a Scottish folk dance in duple meter, the name deriving from the "strath," or valley, of the Spey River in the north of Scotland. The strathspey is related to the reel but it is somewhat slower, its music preferring dotted notes and a "Scotch snap," and while the reel is a gliding dance, the strathspey is rather jerky. Niel Gow (1727-1807) was the most distinguished composer and performer of reels and strathspeys. P. N.

**STRATOSPHERE.** *See* METEOROLOGY.

**STRAUS, OSKAR** [shtrau′s] (1870-1954), Austrian operetta composer, was born in Vienna, Apr. 6, 1870. He studied composition in Vienna with Hermann Grädener and in Berlin with Max Bruch. From 1895 to 1900 he was conductor and composer for the Wolzogenschen Überbrettl in Berlin. *Der tapfere Soldat* (*The Chocolate Soldier*) (1908), based on George Bernard Shaw's comedy *Arms and the Man,* was his most famous operetta, and *My Hero,* the principal soprano song from its score, became one of the most popular songs in the semipopular repertory. *The Waltz Dream,* the title song from the operetta *Ein Walzertraum* (1907), is also very frequently played, usually as an instrumental number. Straus also wrote chamber music. He left Berlin in 1927 and afterwards lived in Paris and the United States, becoming a French citizen in 1939. In addition to many operettas, he has written music for two of Maurice Chevalier's motion pictures, *The Smiling Lieutenant* (based on *Ein Walzertraum*) and *One Hour with You.* None of his later operettas had the success of his earlier works. He died in Bad Ischl, Austria, on Jan. 11, 1954. F. G. P.

**STRAUSS** [shtrau′s], the name of a Viennese musical family, composers of Viennese waltzes and light opera.

**Johann, Sr.** Johann Strauss, Sr. (1804-1849), was one of the most popular writers and performers of light music of his time. It was due to him that Vienna was first considered all over the world as the home of lighter music. He originally played the viola in the quartet of the waltz-composer Josef Lanner, but at the age of twenty-two he founded his own orchestra, which eventually became so successful that he was invited to play at the coronation of Queen Victoria. Among his 251 compositions the best known are the waltzes *Donaulieder* ("Songs from the Danube") and *Das Leben ein Tanz* ("Life is a Dance"). Strauss the elder had three gifted sons.

**Johann, Jr.** Johann Strauss, Jr. (1825-1899), the eldest son, composer of dance music and operetta, was born in Vienna, Oct. 25, 1825. At the wish of his father, he was to become a bank clerk; but he soon won fame both as the conductor of a dance orchestra and as a composer. He was acclaimed as an orchestra leader in Vienna, St. Petersburg, Paris, London, and also in New York and Boston. His waltzes and quadrilles were considered the truest expression of the tenderness, grace, and charm of the Viennese soul, while his operettas rivaled in success those of Alexandre Lecocq and Jacques Offenbach. Strauss had at his disposal inexhaustible sources of melodic invention; he also used interesting harmonies and a fascinating style of orchestration. Such diverse musicians as Arthur Nikisch, Hans von Bülow, Ruggiero Leoncavallo, Johannes Brahms, and Richard Wagner were his ardent admirers. Among his almost five hundred waltzes, *An der schönen blauen Donau* ("The Beautiful Blue Danube") achieved the greatest popularity, being regarded the world over as a sort of joyous and brilliant anthem of Vienna. Almost equally successful were the *G'schichten aus dem Wiener Wald* ("Tales from the Vienna Woods") and *Frühlingsstimmen* ("Voices of Spring"). In Strauss's operettas we find French wit with a definitely Viennese touch, and an unusually artistic interweaving of themes. *Der Zigeunerbaron* ("The Gypsy-Baron") and *Die Fledermaus* ("The Bat") won world fame.

**Josef.** Josef Strauss (1827-1870), the second son, became an architect, owing to the prejudice of his father, who did not want any of his children to become musicians. But his urge to compose was too strong. He formed his own orchestra, for which he wrote no less than 283 pieces of dance music, among them a number of charming mazurkas of an almost Schubertian grace. The full extent of Joseph's talent was discovered only in the twentieth century, when a number of operettas (among them *Frühlingsluft*) using his melodies were performed.

**Eduard.** Eduard Strauss (1835-1916), the youngest son, composed 318 dance pieces, but he was known mainly as the successful interpreter of the dances of the older members of the family. He wrote a book of *Memoirs* (1906), containing valuable biographical material about the whole dynasty. K. G.

**STRAUSS, DAVID FRIEDRICH** (1808-1874), German theologian and writer, was born in Ludwigsburg, near Stuttgart, Jan. 27, 1808. After preparatory study in the seminary at Blaubeuren, he entered the University of Tübingen in 1825, where he came to be profoundly influenced by Hegel and somewhat less by Schleiermacher.

On his return to Tübingen, Strauss was granted the privilege of a *Repetent* tutor, in the University, while he prepared himself to become a member of the faculty of philosophy. Meantime he devoted himself to the completion of a work he had already planned in Berlin and in 1835-1836

published his two-volume *Leben Jesu kritisch bearbeitet;* this appeared in a three-volume English translation, *The Life of Jesus, Critically Examined,* in 1846. Strauss was only twenty-nine years old when he finished the German edition. The conclusion of the second volume contains a speculative Christology which contradicts both the supernaturalistic and the rationalistic conception of Christ and Christology.

Strauss's thought was distinguished by what has become known as the Mythical Theory, or the key to the true meaning of the Gospels and Epistles of the New Testament and even of the prophecies of the Old Testament. By this device he intended to escape both the literalism of the supernaturalists (orthodoxy) and the humanism of the rationalists, who regarded the supernatural facts in the New Testament as mere human inventions and surrendered the divine contents of the Bible. According to Strauss's conception of a myth, it has an element of historical fact around which are woven the religious feelings and ideas of groups of persons at a particular time and place. But these ideas, he argues, are not based on actual historical data, and the infancy narratives in Matthew and Luke, the miracles, the resurrection, and the glorification of Jesus he therefore considers to have no basis in historical fact. To Strauss a myth was a legitimate literary form for the expression of truth which the historian, the philosopher, or the scientist could not present in prosaic form. To use his own words: "Myth is the creation of fact out of an idea; legend is seeing an idea in a fact."

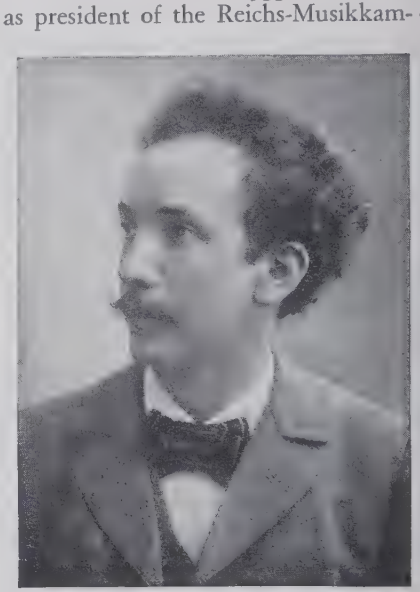
The *Leben Jesu* created a sensation throughout Europe and called forth numerous books and tracts, some of them criticizing and denouncing its author as anti-Christ. Strauss was compelled to leave Tübingen, but was invited to a professorship in the University of Zürich, which, on account of the vigorous protests of clergy and laity, he never accepted. He then retired into private life and lived in Ludwigshafen, Munich, Weimar, Heidelberg, and Darmstadt. He died in Ludwigsburg on Feb. 8, 1874.

Strauss continued to write notable books and did not recant the Mythical Theory. Among these books were *Die Christlichen Glaubenslehre in ihrer geschichtliche Entwicklung und im Kampfe mit der modernen Wissenschaft dargestellt* (1840-1841) ("The Christian Doctrine of Faith in its Historical Development and in its Controversy with Modern Science") and *Das Leben Jesu für das deutsche Volk* (1864) ("The Life of Jesus for the German Nation"), in which he renounced the Church and its creeds. His last work was *Der alte und der neue Glaube* (1872) ("The Old Faith and the New," 1873), and he also wrote a very readable biography on Voltaire, which has not been translated into English. Strauss was a master of German prose, and even his bitterest opponents regarded him as a brilliant writer and a lover of truth.

G. W. R.

**STRAUSS, RICHARD** (1864-1949), German composer, was born in Munich on June 11, 1864. His father, Franz Strauss, was a horn player in the court orchestra, and consequently the boy's musical training started early. When he was still only twenty, his First Symphony in F minor, Op.12, was performed in New York under Theodore Thomas. His early compositions were conventional, and cast in strictly classical forms, but on one of his first conducting jobs, in Meiningen during the season of 1885-1886, he came under the influence of Alexander Ritter. Ritter changed his attitude toward the "advanced" composers of the day, Franz Liszt and Richard Wagner, and Strauss's style underwent such a radical change that for the decades before and after 1900 he and Claude Debussy (born in 1862) were rated as the world's foremost exponents of program music.

In addition to his composing, Strauss built up an enviable reputation as a conductor. He was in much demand all over Europe as a guest conductor, even making two trips to the United States in 1904 and 1922. His principal conductorial jobs, however, were with the Royal Opera in Berlin from 1898 to 1918, and as co-director with Franz Schalk of the Vienna State Opera from 1919 to 1924. Although he was ostensibly in retirement, the National Socialists called him to Berlin in November 1933, and, until June 1935, he served as president of the Reichs-Musikkammer. It has been rumored that his relations with the Party grew cooler with the passing years, but nonetheless he was commissioned to write in 1941 the *Festmusik zur Feier des 2600 jährigen Bestehens des Kaiserlichen Japan,* Op.84, as a gesture of friendship between Germany and Japan. Strauss died at Garmisch-Partenkirchen on Sept. 8, 1949.



*RICHARD STRAUSS*

CULVER SERVICE

Although he has composed works in almost every genre, Strauss is chiefly famous for his songs, tone poems, and operas. Numerically, the songs predominate, with groups of them, either with piano or orchestral accompaniments, published under more than thirty opus numbers. The earlier ones, such as *Zueignung* and *Allerseelen* (from Op.10), *Ständchen* (from Op.17), *Heimliche Aufforderung* and *Morgen* (from Op.27), and *Traum durch die Dämmerung* (from Op.29), are in the best tradition of the German *Lied.* The later songs, however, seem more contrived, and have not won the same spontaneous appreciation.

Among his tone poems, *Aus Italien,* Op.16, is a transitional work, written while he was changing from the classical to the programmatic style. *Don Juan,* Op.20 (performed 1889), was his first great success in the form of the symphonic poem, and with the impudent *Till Eulenspiegels lustige Streiche,* Op.28 (1895), it remains one of his most popular works. *Macbeth,* Op.23 (1890), is rarely heard today, but the dramatic climax of *Tod und Verklärung,* Op.24 (1891), has kept it in the regular repertoire of most orchestras. His later symphonic poems—*Also sprach Zarathustra,* Op.30 (1896), *Don Quichote,* Op.35 (1897), *Ein Heldenleben,* Op.40 (1898), *Sinfonia domestica,* Op.53 (1904), and the *Alpensinfonie,* Op.64 (1915)—produced great clamor and excitement when they first appeared, and several of them remained standard repertory pieces for several decades. By the mid-twentieth century they began to sound over-long,

meandering, and formless, since Strauss almost certainly stretched the binding power of a program too far.

When bolstered with a good text, Strauss's shrewd planning of dramatic effects made him pre-eminent as an opera composer, and three or four of his works in this field are among the best operas of the past half century. His first two, *Guntram* (1894) and *Feuersnot* (1901), were considered "too Wagnerian," complicated, and gloomy, but with *Salome* (1905), set to a translation of Oscar Wilde's play, he startled the whole world. In *Elektra* (1909), he tried to achieve even greater brutality of treatment. A sudden change of pace comes with *Der Rosenkavalier* (1911), with its lovely waltzes, brilliant orchestration, and general spirit of genial sophistication. Most critics feel that altogether it is Strauss's most satisfactory work. The revision (1916) of *Ariadne auf Naxos,* originally performed in 1912, won favorable critiques in 1947, but with the exception of *Arabella* (1933), which is very popular in the provincial opera houses in Germany, the long line of later operas is rarely performed, and needs only be listed for the record: *Die Frau ohne Schatten* (1919), *Intermezzo* (1925), *Die Aegyptische Helena* (1928), *Die schweigsame Frau* (1925), *Der Friedenstag* (1938), *Daphne* (1938), *Capriccio* (1942), and *Die Liebe der Danae* (1944).

R. S. H.

**STRAVINSKY, IGOR** [strʌvyi'nskɜɪ] (1882- ), a leading modern composer, was born in Oranienbaum, near St. Petersburg, Russia, June 17, 1882. His father was an opera singer, and Stravinsky was brought up in a musical environment. Beginning to compose without the aid of formal instruction, he was already in his twenties when he took his first lessons with Rimsky-Korsakov. His first published work, a symphony (1905), is academic in character. Under the influence of Rimsky-Korsakov, Stravinsky became interested in Russian musical folklore. His first important work of Russian national character came in 1910 as a result of his meeting with Diaghilev, the famous Russian ballet impresario, who was then planning a series of performances of Russian ballet in Paris. Stravinsky wrote for him one of his most brilliant orchestral scores, *The Firebird* (1910), based on a Russian fairy tale. The following year Stravinsky composed another ballet, *Petrushka,* in which he depicted with vivid and authentic imagery the Russian carnival scenes. The musical language of *The Firebird* and *Petrushka* still retains a connecting link with earlier musical tradition. With the creation of his third ballet score, *Le Sacre du printemps* (1913), representing scenes of ancient pagan Russia, Stravinsky broke with the musical past. In this work he makes free use of unresolved dissonances and employs constantly changing rhythms of unheard-of complexity. The score is written for a huge orchestra, and the technical demands upon the players are extreme. The first performance of *Le Sacre du printemps* by Diaghilev's ballet in Paris, May 29, 1913, was marked by violent demonstrations on the part of the audience, and Stravinsky's name became symbolic of ultra-modern trends in music.

Before the outbreak of World War I Stravinsky left Russia. He lived in France until 1939, when he settled in America, becoming an American citizen Dec. 28, 1945. This voluntary expatriation resulted in a gradual abandonment of Russian folklore in Stravinsky's music. Russian motives are still present in his score for seven instruments, *History of a Soldier,* written during World War I, and in *Les Noces* (1920), a stylization of a Russian village wedding, scored for voices, four pianos, and seventeen percussion instruments. His later works reveal a tendency toward classical and religious music. To this category belong his Piano Concerto (1924), the ballet *Apollon musagètes* (1927), and particularly the modern cantata, *A Symphony of Psalms* (1930). During the same period Stravinsky wrote musical scores based on themes of Pergolesi (*Pulcinella,* 1920) and Tchaikovsky (the ballet *Baiser de la fée*). The score of his *Symphony in Three Movements* (1945) is a synthesis of his neoclassical manner and the revolutionary style of the period of *Le Sacre du printemps.*

The influence of Stravinsky on contemporary music is very great. National composers in countries as widely separated as Spain, England, and the United States have experienced at one time or another the powerful impact of Stravinsky's music, either in its neoprimitive Russian manner or in the later neoclassical style. Young composers in America, especially, have eagerly followed the new paths opened by Stravinsky's novel use of classical techniques. N. Sl.

**STRAWBERRY,** the common name for the so-called fruit of the genus *Fragaria* of the rose family, with about 20 species, all low perennial herbs, native to the North Temperate Zone and to high altitudes of tropical South America.

THOMÉ - DR. LASCOFF

*A wild strawberry plant of the genus Fragaria, showing leaf, flower, fruit, and seed*

Strawberries have long been grown for the highly prized, delicious fruits, which are in reality juicy, fleshy red receptacles, which bear imbedded on their surface the small, seedlike true fruits. The plants send out long slender runners which root to produce new plants. The trifoliate leaves and the flower stalks with their clusters of white or reddish flowers rise from a low crown. Strawberries have been cultivated in Europe for at least 500 years. The Virginia strawberry, *Fragaria virginiana,* was introduced into England in 1629, and the Chile strawberry, *F. chiloensis,* into France in 1715. When North America was first settled, the wild strawberries were so plentiful that there was no garden culture of the fruit until about 1770. Commercial strawberry growing began about 1800, near the largest cities; strawberries are now a leading small fruit in the United States, their culture extending from Florida to Alaska.

The strawberries most commonly grown are derived from three main species. The Chilean strawberry grows near the coast from Alaska to Patagonia. The flowers and fruits

are hidden under the leaves, and the seeds sunk in pits on the receptacles. A form, the pine strawberry, var. *ananassa,* considered a species or hybrid by some botanists, is believed to be the parent of most garden varieties. The European strawberry, *F. vesca,* native to the Old World and northern North America, has flowers and fruit borne above the foliage and the seeds on the surface of the fruits. It is the source of European Alpine strawberries, some of the everbearing varieties, and various white fruited forms. The Virginia strawberry, widespread in North America, and the common wild strawberry of the eastern part, resembles the Chile strawberry and may be with it a parent of the pine strawberry. It has also been used as a more recent parent of modern varieties.

**Cultivation.** Strawberry plantations are made from the runners produced by old plants. In home gardens, well rooted runners can be set out in late summer and early fall and with good care and favorable conditions will bear well the following summer. In the South, commercial plantings made in late summer give a winter crop. In the North, commercial plantings are made in early spring. The first year, the plants and runners produced by them are well cared for to give a fine crop the following year. Well-cared-for plantings will produce for five or six years, but it is the usual commercial practice to have new beds coming along and to plow up the old ones after one cropping. There are several methods of growing these plants. In the matted row system, widely used commercially, all plants and their runners are allowed to grow. In the hedge row system, the runners spreading beyond a strip 12 to 18 in. are cut off. The hill system is used to produce the highest quality of strawberry. Here no runners are allowed to develop. Strawberries require a well-drained, fertile, moist soil, and thrive in cool weather. Only young plants that have not borne should be planted. When only a few are needed, runners can be made to root in pots of soil sunk in the ground near parent plants. When they have rooted well, the young plants can be placed in the new location. The crowns must be set just above soil level; if too deep, they will rot, if too shallow the roots will dry out. In the North, the plants should be well mulched to prevent heaving.

**Varieties.** Varieties of strawberries are adapted to certain small areas. Among those that thrive in the east and middlewest are: Howard, Clermont, Dresden, Culver, Catskill, Fairfax, and Chesapeake; in Florida and the Gulf States are Klondike, Missionary, and Aroma. Varieties grown on the Pacific Coast are: Clark, Dollar, Magoon, Marshall, and Oregon. Home fruit growers usually like to have a few fall bearing varieties of which the best are: Rockhill, Mastodon, and Gem. E. L. Sh.

**STRAWBERRY BASS.** *See* CRAPPIE, CALICO BASS, or STRAWBERRY BASS.

**STRAWBERRY GERANIUM,** a hairy perennial, *Saxifraga sarmentosa,* of the saxifrage family, native to China and Japan. It resembles the strawberry in its running habit of growth. In mild regions, it is cultivated as a garden ornamental, and in the North as a house plant, or under glass. The long-stalked, rounded leaves, white-veined above and reddish below, lie close to the ground; but the slender, erect flower stalks are sometimes 2 ft. high and bear open clusters of delicate, pinkish-white flowers. J. C. Wis.

**STRAWBERRY GUAVA** [gwɑ′və], a Brazilian shrub or tree, *Psidium cattleianum,* growing to about 25 ft. tall, of the myrtle family, closely allied to the common guava, and cultivated in California, Florida, and other warm regions for its edible fruit. It has smooth, dark green, leathery, rather oblong leaves, and large, white, solitary flowers. The sweet, aromatic fruit, 1 to 1½ in. long, is roundish, with thin, purple-red skin and soft, whitish flesh containing numerous hard seeds; it tastes somewhat like a strawberry. J. C. Wis.

**STRAWBERRY TREE,** a handsome evergreen tree, *Arbutus unedo,* of the heath family, which is widely grown for ornament in mild climates. In autumn, it bears nodding clusters of white or rose-colored flowers which are followed by showy fruits, scarlet in color and berrylike in shape. The glossy green leaves are oblong, and the tree usually grows 10 to 15 ft. high in cultivation. It is a native of the Mediterranean region, and is closely allied to the madroña. The name is also applied to various species of spindle tree, *Euonymus. See also* EUONYMUS. J. C. Wis.

**STRAW CAT.** *See* PAMPAS CAT.

**STREATOR** [stri′tər], a city in La Salle Co., in northern Illinois, located 48 mi. northeast of Peoria, on the Vermilion River. Coal and shale are found in the vicinity. The city, founded in 1868 and known first as Hard Scrabble and Unionville, was incorporated in 1882. It is governed by a commission. Transportation for this industrial community is supplied by the Atchison, Topeka and Santa Fe, the Wabash, the New York Central, the Chicago, Burlington & Quincy, the Gulf, Mobile and Ohio railroads. There are railroad shops in the city, and the factory output includes glass bottles, furniture, brick, tile, farm implements, truck bodies, and foundry products. Pop. 1950, 16,469.

**STREETCARS, ELECTRIC.** Electric streetcars for city passenger transportation, introduced about 1884, had iron underframes, supported by two axles with rigidly mounted wheels driven by electric motors through spur gears. A body was mounted on the frame, its length being limited to about 20 ft. by the rigid wheelbase. Early in the twentieth century, a car with two swiveling trucks succeeded it, permitting the car to go around sharp curves and making greater length. City cars are as much as 50 ft. in over-all length and seat up to sixty persons.

Practically all streetcars built in the United States since 1935 are of the type designed under the supervision of the Electric Railway Presidents' Conference Committee (P.C.C.). The cars embody results of extensive experiments in mechanical performance, noise reduction, comfort, heating, and ventilation. Body framing is of pressed steel with roof, sides, and underframe welded to form one structure. The body is mounted on double trucks in which rubber is inserted at all moving joints, replacing steel springs. Wheels have rolled steel treads, separated from the hubs by annular rubber disks.

Four 55-hp. motors, one geared flexibly to each axle by hypoid gearing with a speed reduction of approximately 7 to 1, drive the car at speeds up to 45 m.p.h. Control is rheostatic, starting being governed by insertion of resistance in series with the motors. Highest speeds are obtained by field weakening. Relays protect the equipment and assure smooth acceleration of 3 to 4 miles per hour, per second. The main controller, placed under the car, is actuated by a pedal as in an automobile.

Braking is a combination of dynamic and pneumatic in the older P.C.C. cars, and all-electric since the 1946 model. A supplementary solenoid track brake, taking current directly

from the trolley, consists of shoes mounted between the wheels, the shoes being pulled toward the rails magnetically. Early P.C.C. cars completed the stop below about 5 m.p.h. (the lower limit of dynamic braking) with air brakes, the shoes pressing against the wheel treads as in railroad practice, and being controlled by the same pedal as the dynamic brake. Starting with the 1946-model car, dynamic braking was carried to less than 1 m.p.h. The air brakes have been replaced by drum brakes on the motor shaft, which are applied by springs and released by solenoids. No hand brake is necessary.

Forced ventilation is used on all P.C.C. cars. Air drawn through ducts leading from the roof is passed into a chamber under the car where waste heat from the control resistors, and electric heat directly from the trolley wire, warm it in winter. It then is distributed in ducts to the car interior. In early designs of the car some 1,200 to 1,500 cu. ft. of air per minute circulated, whereas in the 1946 design the rate is 12,000 to 14,000 cu. ft. per minute. A motor-generator-blower unit adjacent to the air chamber circulates the air and forces it through the motors and resistors. It also supplies 32-volt current for charging a storage battery that furnishes power for control and auxiliary equipment.

Weight of the standard car is 36,000 lb., of which approximately 17,200 lb. is in the body, the remainder consisting of trucks, motors, and electrical equipment. *See also* ELECTRIC TRACTION; TROLLEY BUSES. M. Bu.

**STREITBERG, WILHELM AUGUST** [shtrai'tbɛrχ] (1864-1925), German linguist, was born at Rüdesheim, in the Rhineland, Feb. 23, 1864. After teaching at Freiburg in Switzerland, and at Leipzig, Münster, and Munich, he succeeded Karl Brugmann at Leipzig in 1920. He was one of the leading linguists of his generation, his main fields being the Germanic languages and Indo-European.

Streitberg's *Urgermanische Grammatik* (1896) presents, in admirably condensed form, the essential results of the investigations that had at that time been made into the structure of Primitive Germanic. His *Gotische Bibel* (1908-1910), a monumental work, presents an excellent historical grammar of Gothic, all the Gothic texts critically analyzed, and the Greek text from which the Gothic was translated. Streitberg also investigated the difficult problem of the Indo-European vocalic alternations (*Die Entstehung der Dehnstufe,* 1894) and its relationship to the accent, in a work that is still fundamental. He founded, with Brugmann, the *Indogermanische Forschungen* (1891), for a long time the main linguistic journal of the world, and directed it alone at Brugmann's death in 1919; he also published alone, from its inception, the excellent bibliographical and critical supplement (*Indogermanischer Anzeiger*). Streitberg instituted the famous *Germanische Bibliothek* in 1896, founded the *Indogermanische Gesellschaft* in 1912, and directed that society's *Indogermanisches Jahrbuch* with A. Thumb and later with A. Walde. Before his death he also completed the first part of a work, posthumously published, entitled *Germanisch*. Streitberg died in Leipzig on Aug. 19, 1925. G. B.

**STRENGTH OF MATERIALS,** the branch of applied mechanics that treats of stresses and deformations resulting from forces acting on solid bodies. Other names for this branch of mechanics are mechanics of materials and mechanics of elastic bodies.

Stress in a body due to applied loads is the force per unit of area (pounds on each square inch) that one part of the body exerts on an adjacent part. Deformations of a body resulting from applied loads are the changes in the dimensions or size and shape of the body. Strength of materials investigates the relationships between loads, stresses, and deformations in two ways: (1) by the mathematical derivation of formulas expressing relationships between loads and resulting stresses and deformations; and (2) by experimental methods including testing of materials used in structures and machines to determine the properties of such materials. The relationships derived analytically and the data found by testing are used to determine the necessary sizes of members in structures and machines that support given loads. Strength of materials is not an exact science because many relationships employed are based on assumptions concerning the behavior of materials that are not exactly true. Nevertheless, it furnishes satisfactory tools with which competent designers achieve safe and economical structures.

Some knowledge of strength of materials existed when the ancient Greeks and Romans built their large structures, but the modern science began at the time of Galileo Galilei, whose researches led to faulty results but who was the first of a succession of mathematicians, physicists, and engineers to contribute to the science. In the past, much of the science was developed in universities and engineering schools. Currently, progress is being made by research in engineering schools, and in commercial, industrial, and government-supported laboratories such as those of the Bureau of Standards and the Forest Products Laboratory. Special committees of the national engineering societies also make notable contributions.

Closely allied to strength of materials is the mathematical theory of elasticity, a science also concerned with stress and deformation. Through use of the theory of elasticity, problems may be solved that do not yield readily to the usual methods of strength of materials. There is no well-defined boundary between advanced strength of materials and the mathematical theory of elasticity. Most of the problems of stress variation have been solved by mathematical analysis, but in cases involving very complicated conditions the mathematical solutions may become extremely laborious or even impossible. Ingenious experimental methods of stress analysis have been devised that have been successfully applied to such cases. The Society for Experimental Stress Analysis, organized in 1943, serves as a medium for the exchange of knowledge of such methods.

## STRESS AND DEFORMATION

**Types of Stresses.** The most important concept in strength of materials is that of unit stress or intensity of stress. Stresses are of three kinds: tensile, compressive, and shearing.

If a load is suspended by a metal bar, as shown in Fig. 1, the bar is said to be a tension member. If the load weighs 10,000 lb., the tension in the bar is 10,000 lb. If the bar is 2 in. wide and 1 in. thick, and thus has a cross-sectional area of 2 sq. in., the stress intensity or tensile unit stress is 5,000 lb. per sq. in. When the unit stress is uniform over the cross section, as in this example, the unit stress $S$, caused by a load $P$ on a tension member having a cross section of $A$ square inches, is given by the formula $S = P/A$. A body while stressed in tension is longer than when unstressed.

If a short prism (Fig. 2) rests on a floor and a load is placed on its upper end, and is supported by it, there is compressive stress on all cross sections of the prism. If this stress is uniform over the cross section, the unit stress $S$ is given by the formula $S = P/A$. A prism stressed in compression is shorter than when unstressed.

An illustration of shearing stress is provided by the bolt shown in Fig. 3*a* which holds the upper end of the tension member *AB* in Fig. 1. The bolt supports the bar by exerting an upward force of 10,000 lb. on the part of the bar just above the hole in the bar, and the bar, in turn, bears down on the middle section of the bolt with a force of 10,000 lb.

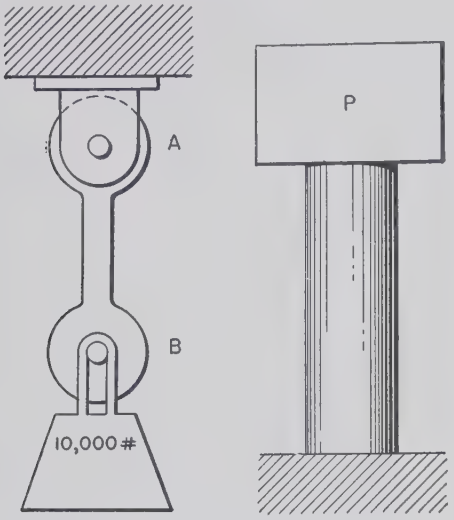


*Fig. 1* (LEFT)—*ILLUSTRATION OF A TENSION MEMBER; Fig. 2* (RIGHT)—*ILLUSTRATION OF A COMPRESSION MEMBER*

The forces on the bolt are applied as shown in Fig. 3*b*. If the bolt were made of a material of low shearing strength, such as lead, it would be sheared off on two vertical planes as shown in Fig. 3*c*. If the bolt is of steel and of sufficient diameter, it will not fail but there will be shearing stress on each of two vertical cross sections. When shearing stress is uniformly distributed its value is given by $S_s = P/A$. The total shearing force on each of the two cross sections of the bolt is 5,000 lb., and if the bolt is 1 in. in diameter (cross-sectional area 0.785 sq. in.), the unit shearing stress is $S_s = 5{,}000/0.785 = 6{,}370$ lb. per sq. in.

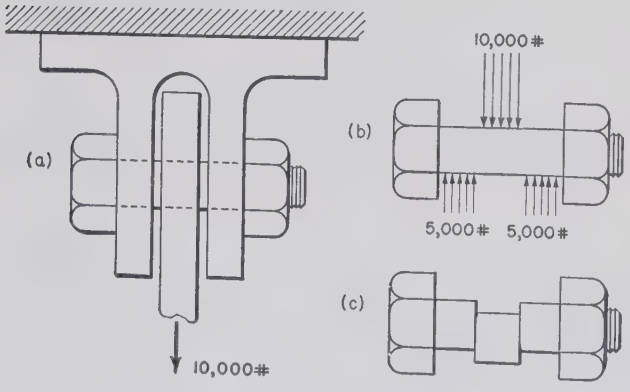

*Fig. 3—ILLUSTRATION OF SHEARING STRESS IN A BOLT*

It should be noted that, in tensile and compressive stresses, the planes on which the stresses occur are perpendicular to the direction of the stresses, but, in shearing stress, the planes on which shearing stresses act are parallel to the stresses. Because of this distinction, tensile and compressive stresses are called normal stresses, and shearing stress is called tangential stress.

**Deformation or Strain.** In a body to which loads are applied, changes in dimensions caused by the loads are called deformations or strains. Deformation that occurs in a unit length is called unit deformation. If every inch of length changes the same amount, the unit deformation is uniform. The symbol $\delta$ is often used for unit deformation and $\Delta$ for total deformation. If the unit deformation throughout a length $L$ is constant, then $\delta = \Delta/L$. For example, if a bar of steel 80 in. long before a tensile load is applied is 80.06 in. long when loaded, total deformation $\Delta$ is 0.06 in. and the unit deformation $\delta = 0.06/80. = 0.00075$ inches per inch.

For nearly all materials used in structures and machines, unit deformation is proportional to unit stress, provided that unit stress does not exceed a value called the proportional limit. This very important relationship is known as Hooke's Law. It was discovered experimentally and stated by Robert Hooke, an English clockmaker, in 1678. The relationship between stress and deformation for any material is given by the formula $S = E\,\delta$, in which $E$ is a constant for a material. Physicists call this constant Young's Modulus, after Thomas Young, who defined it in 1802; engineers call it the modulus of elasticity. Steel has the highest modulus of elasticity of all common engineering materials, the value being about 30,000,000 lb. per sq. in. In a bar of steel, a unit deformation of 0.00075 in. per in., as in the example above, would be caused by a unit stress $S = E\delta = 30{,}000{,}000 \times 0.00075 = 22{,}500$ lb. per sq. in., a stress well within the proportional limit. If, on the other hand, the bar were of aluminum with a modulus of elasticity of 10,000,000 lb. per sq. in., a stress of only 7,500 lb. per sq. in. would cause the same deformation of .00075 in. per inch. It is thus evident that the elastic

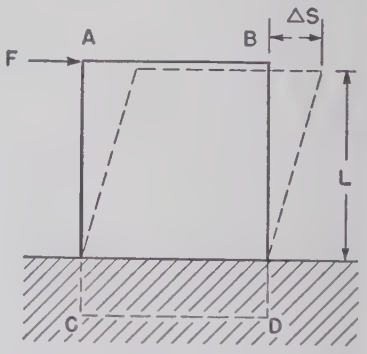

*Fig. 4—VISUALIZATION OF SHEARING DEFORMATION*

deformations that occur in structures and machines are very small. Even with the relatively high unit stress of 22,500 lb. per sq. in. in the above example, the deformation of the steel bar is less than one-thousandth of the length. A steel member 30 ft. long would lengthen about one-quarter of an inch when stressed to a rather high tensile unit stress. This great stiffness of steel is a valuable quality.

Shearing deformation is less easily visualized than is tensile deformation or compressive deformation. As an example, consider a rectangular prism *ABCD* (Fig. 4). The lower end is shown as tightly embedded in some rigid body. If a horizontal force of $F$ pounds is applied to the upper end of the prism, shearing deformations will result as indicated by the dotted lines. The displacement $\Delta$ is the total shearing deformation that occurs in the length $L$. Unit shearing deformation is given by the formula $\delta = \Delta/L$. Hooke's Law also holds for shearing deformations, provided that the shearing unit stress does not exceed the shearing proportional limit. Consequently, $S_s = E_s\,\delta$, in which $E_s$ is the shearing modulus of elasticity, often called the modulus of rigidity. For any material, $E_s$ is less than $E$. For steel, $E_s$ is about

2/5 of $E$, or about 12,000,000 lb. per sq. in. An important case of shearing deformation occurs in shafting subject to torsional moments (twisting action).

The deformations discussed so far are elastic deformations resulting from stresses not exceeding the proportional limit. When a body is stressed beyond its proportional limit, deformations increase more rapidly than the stresses. Hooke's Law no longer holds true. In the case of structural steel, when the stress is somewhat above the proportional limit, a small increase in stress is accompanied by an increase in deformation which is many times the elastic deformation caused by stress equal to the proportional limit. The stress at which this increase in deformation occurs is called the yield point of the steel. A material is said to be ductile in which large nonelastic deformations occur before fracture.

## ALLOWABLE STRESSES

Allowable unit stress, or simply allowable stress, is the unit stress value specified as proper for use in calculating the dimensions of the cross section of a member which is to carry a stated load. There are allowable stresses in tension, compression, and shear. Allowable stresses are either specified by some authority (such as the bridge department of a railroad) or selected by a designer who has adequate knowledge of the conditions of use and the properties of the material. The term working stress is often used for allowable stress.

The aim of structural design in general is to obtain structures that are safe and as light as possible; unnecessary weight is costly. Safety is insured by making each member of such size that the maximum stress in the member is less to a proper degree than the stress at which failure occurs in the material used. Failure does not necessarily mean fracture. A machine or structure fails when it will no longer perform its function satisfactorily. A member made of a ductile material will generally fail if the stress reaches the yield point, because at that stress excessive deformation occurs, rendering the machine or structure useless; on the other hand, if a member is made of a brittle material there is very little distortion and failure occurs when the member breaks.

**Margin of Safety.** The difference between the allowable stress, and the stress at which the material will fail, constitutes a margin of safety which is necessary to provide for: (1) accidental or careless overloading; (2) inexactness of calculation of stress due to simplifying assumptions or unknowable conditions; (3) possible defects in the material that cannot be detected; and (4) possible future deterioration due to corrosion or decay. How large the margin of safety should be is a question, the answer to which requires sound engineering judgment based on experience and a thorough knowledge of all conditions of use and of the behavior and characteristics of the material. Allowable stresses for many materials and uses have been specified by competent authorities and these are widely used by designers.

Examples of widely-used specification of allowable stresses are the *Boiler Construction Code* of the American Society of Mechanical Engineers and the *Specifications for the Design, Fabrication and Erection of Structural Steel Buildings* issued by the American Institute of Steel Construction. Parts of the latter specifications have been incorporated in the building codes of many cities. Specifications are revised at intervals as materials are improved or as other conditions change. An example of the amount of the allowable stress as compared to the yield point and ultimate strengths of the material is taken from the 1946 A.I.S.C. specifications. According to these specifications, the steel for buildings must have an ultimate tensile strength between 60,000 and 72,000 lb. per sq. in. and a yield point not less than 33,000 lb. per sq. in. The specified allowable tensile stress for such steel is 20,000 lb. per sq. in., while many more conservative specifications give the allowable tensile stress as 18,000 lb. per sq. in. A very high allowable stress, 82,000 lb. per sq. in., has been used in designing suspension bridge cables, the specified strength of the steel wires being 220,000 lb. per. sq. in. and the yield point 150,000 lb. per sq. in.

**Factor of Safety.** The factor of safety of a member in a structure is the ratio of the load causing failure to the load causing the allowable stress. For most members, stresses are proportional to the loads and, consequently, the factor of safety is often defined as the ratio of ultimate strength to allowable stress. Thus, if the ultimate strength of structural steel is 72,000 lb. per sq. in. and the allowable stress is 18,000 lb. per sq. in., the factor of safety is four. The term factor of safety, as thus defined, is misleading because a tension member, for instance, would cease to be useful (and would, in that sense, fail) when the stress equals the yield point of the material, about 33,000 lb. per sq. in. for structural steel.

## UNIFORM STRESS DISTRIBUTION

A large part of strength of materials is concerned with the derivation of relationships between given loads, the size and shape of the solid body supporting or resisting the loads, and the resulting unit stresses on a certain cross section of the body. In general, the purpose is to determine the necessary dimensions of the body so that the greatest stress that occurs shall not exceed the allowable stress.

Elementary strength of materials deals with a number of cases of uniformly distributed stress. Among these may be mentioned: tension members, short compression members, thin-walled cylinders resisting internal fluid pressure (tanks and boilers), riveted joints, welded joints, temperature stresses, and statically indeterminate combinations, such as axially loaded tension members of two or more different materials.

If the unit stress is the same on all parts of the cross section, then $S = P/A$. The designer determines the necessary cross-sectional area by dividing the given load by the allowable stress. The beginner, however, must learn to distinguish between cases in which the stress distribution is uniform and other somewhat similar cases in which it is not. It is also necessary (as in the case of riveted joints, for example, in which tensile, compressive and shearing stresses all occur) to learn how to recognize the planes on which each of these stresses occurs and how to find what part of the load is resisted by the stress on each plane.

**Thin-walled Cylinders.** To illustrate, consider a tank or thin-walled cylinder. Such a tank will fail (burst) when

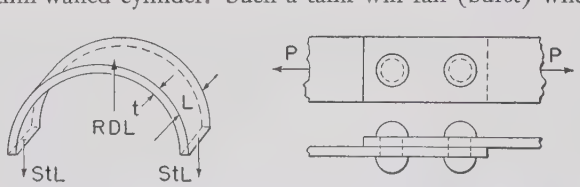

*Fig. 5* (LEFT)—*HALF-HOOP FROM A THIN-WALLED CYLINDER, SHOWING VERTICAL FORCES ACTING; Fig. 6* (RIGHT)—*DOUBLE-RIVETED LAP JOINT*

the tensile stress in the shell becomes equal to the tensile strength of the plate. A formula relating the thickness $t$ of the plate, the internal diameter $D$ of the tank, the stress $S$ in the shell plate, and the internal pressure $R$ (lb. per sq. in.) can be derived by passing two imaginary, transverse planes

$L$ inches apart, cutting the tank. Between these two planes will be a hoop cut from the tank shell. The upper half of this hoop, shown in Fig. 5, is considered as a body in equilibrium. The internal pressure acting on the inner curved surface exerts an upward vertical force equal to $RDL$ and stresses on the two horizontal cut surfaces of the half-hoop exert two downward forces each equal to $tLS$. Equating,

$$RDL = 2tLS, \text{ whence } S = RD/2t.$$

**Riveted Joints.** As an illustration of stresses in a riveted joint, consider two plates joined by two rivets, as shown in Fig. 6. A joint of this type is known as a double-riveted lap joint. Such a joint may fail by shearing off both rivets, by tension in either one of the plates where weakened by the rivet hole, and by excessive bearing stress between the rivets and the plates. Allowable stresses are assumed to be: (1) shearing, 10,000 lb. per sq. in.; (2) tension, 15,000 lb. per sq. in.; and (3) bearing, 20,000 lb. per sq. in. Bearing stress in a riveted joint is defined as the load on one rivet divided by the product of the diameter of the rivet and the thickness of the plate. Let it be required to determine the greatest load $P$ that will not cause stresses greater than the allowable stresses. Each plate is 3 in. wide, ½ in. thick and the diameter of the rivets is 1 in. The area of the cross section of a 1-in. rivet is $\pi \times \frac{1}{4} = 0.785$ sq. in.

(1) $P_s = 2 \times .785 \times 10{,}000 = 15{,}700$ lb.
(2) $P_t = (3 - 1)\frac{1}{2} \times 15{,}000 = 15{,}000$ lb.
(3) $P_b = 2(1 \times \frac{1}{2}) \times 20{,}000 = 20{,}000$ lb.

The smallest of these three values is the allowable load on the joint.

In general, it is true that the stress on a cross section of a tension member or short compression member will be uniformly distributed if the equal and opposite tensile loads are so located that the resultant of each load passes through the centroid of the cross section. There are some cases of nonuniform stress distribution that are dealt with as if the stress were uniformly distributed, such as the case of bearing stress between a rivet and plate in a riveted joint. However, such simplifications must be used with caution.

## NONUNIFORM STRESS DISTRIBUTION

Many structural members and machine parts are so loaded that the unit stresses are not uniform over any cross section. Formulas by means of which stresses may be calculated under these conditions are derived as follows. An imaginary plane containing the cross section on which the stress is wanted cuts the body into two parts, one of which is considered as a body in equilibrium. On this body are one or more given external forces and also the forces resulting from the stresses on the cross section; the stresses must be such that the conditions of equilibrium are satisfied, and must vary in such a way as to be consistent with the deformations of the body. These two conditions lead to the solution of the problem. The second of these two conditions depends upon Hooke's Law. The most common cases of nonuniform stress are: beams, tension or compression members with bending, shafting subject to twisting forces, and columns.

**Beams.** A beam is a long member with transverse loads and supports. Most beams have the same cross section from end to end. The forces exerted by the supports are called reactions. Two types of beams in common use are cantilever beams and beams with two supports, called simple beams. These are represented diagrammatically in Fig. 7. When a beam is loaded, the deformation takes the form of bending. In the simple beam the fibers at the upper surface shorten and those at the lower surface lengthen. It follows that somewhere between the top and bottom of the beam there is a surface that does not change in length. This is called the neutral surface. It is also true that the change in length of any fiber located between the neutral surface and the top (or bottom) of the beam is proportional to the distance of

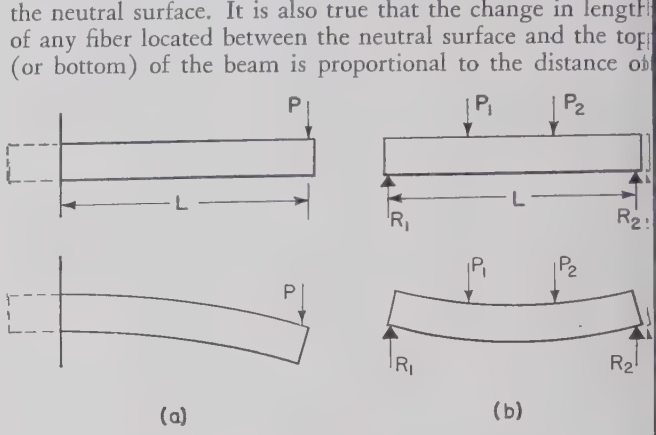

*Fig. 7—TWO COMMON TYPES OF BEAMS*
*(a) Cantilever beam; (b) Simple beam*
*(P, $P_1$, $P_2$) Loads; ($R_1$ and $R_2$) Reactions; and (L) Length*

the fiber from the neutral surface. If Hooke's Law holds, the unit stresses are also proportional to the distance from the neutral axis.

*Flexure Formula.* This law of stress variation, together with the conditions of statics, results in a formula, called the flexure formula, that relates the stresses to the loads and dimensions of the beam. The flexure formula is generally written in the form $S = Mc/I$, in which $S$ is the maximum stress on the cross section, $c$ is the distance from the neutral axis of the cross section to the most stressed fiber, $M$ stands

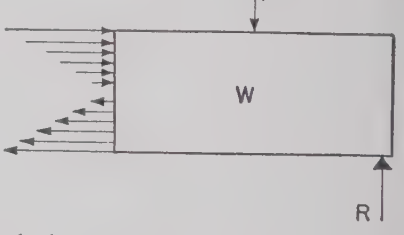

*Fig. 8—VARIATION OF STRESS ON THE CROSS SECTION OF A BEAM*
*(P) Load; (R) Reaction; and (W) Weight*

for bending moment, which is the sum of the moments of all forces on one side of the section, and $I$ stands for the moment of inertia of the cross section and is a function of the shape and size of the cross section. The variation of stress on the cross section of a beam is shown in Fig. 8.

As an example of the calculation of stress in a beam, consider a beam of wood 4 in. wide, 6 in. deep, and resting on supports 120 in. apart. Let it be required to find the maximum bending stress due to a single load of 1,000 lb. at the mid-point of the beam. Because of symmetry, each reaction is 500 lb. The maximum bending moment in a beam with this loading occurs at the mid-point and equals the reaction times half the distance between supports, or $M = 500 \times 60 = 30{,}000$ lb. in.

The moment of inertia of a rectangle is found by the formula $I = \frac{bh^3}{12}$. For this beam $I = \frac{4 \times 6^3}{12} = 72$. The quantity $c$ in this case is half the depth of the beam, or 3 in. Substituting these values:

$$S = \frac{Mc}{I} = \frac{30{,}000 \times 3}{72} = 1{,}250 \text{ lb. per sq. in.,}$$

a rather low stress for any of the common structural timbers.

There are also shearing stresses on cross sections of beams, and the resultant force exerted by the shearing stresses equals the sum of all other vertical forces on one segment of the beam. The sum of all the external loads and reactions on one of the two segments of the beam is known as the shear at the section of the beam and is generally given the symbol $V$. The shearing stresses are not uniform over the cross section, being of zero intensity at the top and bottom edges and nearly always of maximum intensity at the neutral axis.

**Deflections of Beams.** It is often necessary to calculate the amount of the vertical movement or deflection of a point on the neutral surface of a beam as it is bent by loads. This problem is of great importance because an understanding of the deflections and the curvature of beams contributes greatly to the solutions of problems arising in a large class of frames known as indeterminate structures.

As early as 1757, the Swiss mathematician Euler wrote an equation representing the curve of a bent beam. The equation relates the curvature of the beam to the variable bending moment. To find the ordinate of the elastic curve (the deflection) requires the use of the method of double integration. In 1868, Professor Otto Mohr, in Germany, and, in 1873, Professor Charles E. Greene, at the University of Michigan, independently discovered a method making use of the bending moment diagrams of beams. This method is known as the area-moment method and has the great advantage of reducing the mathematics to relatively simple arithmetic. By the methods mentioned, it is possible to calculate the deflection or slope at any point in a beam with any kind of loading. For simple types of loading, formulas for the maximum deflections are readily derived. Two examples of such formulas are: for a cantilever beam with a concentrated load of $P$ at the end, the maximum deflection $y = PL^3/3EI$; for a beam on supports at the ends and with a uniform load $W$ over the entire length, $y = 5WL^3/384EI$.

**Statically Indeterminate Beams.** Many beams used in structures and machines have more than two reactions or have two reactions with one or both ends fixed against rotation. Such beams are called statically indeterminate beams because the equations furnished by statics are not sufficient

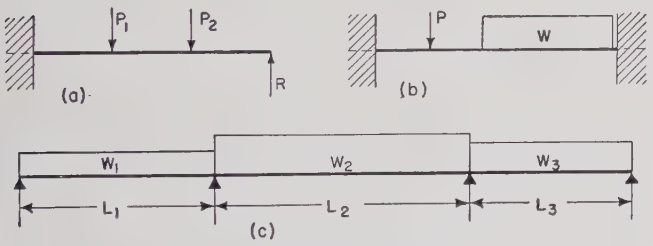

*Fig. 9—INDETERMINATE BEAMS*

*(a) Beam fixed at one end; (b) Beam fixed at both ends; and (c) Continuous beam of three spans*

*($P$, $P_1$, $P_2$) Loads; ($R$) Reaction; ($L_1$, $L_2$, $L_3$) Lengths; ($W$, $W_1$, $W_2$, $W_3$) Weights*

for the determinations of the reactions and end moments. The three types usually studied are: beams fixed at one end and with one support, beams fixed at both ends, and continuous beams (having more than two supports) as shown in Fig. 9. The necessary additional equations for solving such beams are based on conditions of deflection and curvature.

The first solution of continuous beams was published by the French engineer, E. Clapeyron, in 1857. He derived a formula now called the theorem of three moments. This formula, written in many different forms, expresses a relationship that exists between the three bending moments at three successive supports in a continuous beam. As an example, for a continuous beam with a uniform load on each span, the formula is:

$$M_A L_1 + 2M_B(L_1 + L_2) + M_C L_2 = -\frac{W_1 L_1^3}{4} - \frac{W_2 L_2^3}{4}.$$

In this formula, $M_A$, $M_B$ and $M_C$ are the bending moments at the three supports, $L_1$ and $L_2$ are the lengths of the left and right spans, $W_1$ is the load on the left span and $W_2$ is the load on the right-hand span. It is necessary to write this equation for each pair of adjacent spans and then to solve these equations simultaneously. If there are $n$ spans there will be $n - 1$ equations.

In 1930, Professor Hardy Cross published a method for solving a large variety of indeterminate frames, including continuous beams. This method is called moment distribution and avoids the solution of simultaneous equations reducing the calculations to addition and subtraction of numbers.

**Torsional Stress.** If equal and opposite torques or twisting moments are applied to the ends of a piece of shafting, there will be shearing stresses on every cross section. On any circular cross section the shearing stress is zero at the center and of maximum intensity at the outer edge; between these points the unit stress is proportional to the distance from the center. The common torsion formula giving the maximum shearing stress is: $S_s = Tc/J$, in which $T$ is the torque at one end in pound inches, $c$ is the radius of the shaft, and $J$ is the polar moment of the cross section. For a circle, $J = \frac{\pi r^4}{2}$. This torsion formula applies only to circular cross sections. The derivation of formulas for shafts of other cross sections is a problem solved by the mathematical theory of elasticity, aided, in some cases, by ingenious methods of experimental analysis.

As an example of the use of the torsion formula, let it be required to find the allowable torque that may be applied to (or resisted by) a 3-in. diameter steel shaft if the allowable shearing stress $S_s$ is 8,000 lb. per sq. in.

For this problem, the formula is written $T = S_s J/c$. For a 3-in. shaft, $J = \frac{\pi \times 1.5^4}{2} = 7.96$ in.$^4$ and $c$ is the radius of the shaft, 1.5 in. Substituting these values, $T = 8{,}000 \times 7.96/1.5 = 42{,}500$ lb. in. This torque could be exerted by a belt pull of 1,700 lb. at a radius of 25 in., or by any other combination of force and radius such that the force times the radius equals the torque.

**Combined Bending and Direct Stress.** Beams often have tension or compression forces on the ends in addition to the transverse loads and reactions, and there are other cases where tension or compression exists in addition to bending. In such cases, the unit stress at any point in any cross section is the algebraic sum of the direct stress due to the loads perpendicular to the cross section and the bending stress due to the transverse loads. The general formula for combined bending and direct stress is $S = \pm (P/A) \pm (Mc/I)$, in which the plus sign is commonly used to denote tensile stress.

An important case is that of a prism with an eccentric load on the end. As an example, consider the bar $AB$ in Fig. 1 and imagine that the holes at the ends of the bar are not on the geometric axis of the bar but are drilled ¼ in. to the right of this axis. The effect of this eccentricity is

to cause bending stress in addition to the direct tensile stress. The bending moment equals the product of the load and the eccentricity; in this case $M = 10{,}000 \times \frac{1}{4} = 2{,}500$ lb. in. For this bar 1 in. thick and 2 in. wide, $I = 0.67$ in.$^4$ and $c = 1$ in. The formula gives:

$S = +(10{,}000/2) \pm (2{,}500 \times 1/067)$

$= +5{,}000 \pm 3{,}750 = +8{,}750$ lb. per sq. in. at the right edge and $+1{,}250$ lb. per sq. in. at the left edge. Shifting the load only $\frac{1}{4}$ in. has increased the tensile stress by 75 per cent.

**Columns.** Building frames and bridges consist largely of tension members, beams, and columns. Columns are long compression members with loads on the ends. In a building frame, the vertical members that support the floors are columns.

If a compression member is more than 10 or 15 times as long as it is wide, it will bend when loads are applied to the ends, even if the loads are intended to be axial. Due to this bending, the load is eccentric on the cross section at the mid-length of the column. If $D$ is the amount of this eccentricity, the maximum compression stress in the column is $S = (P/A) + (PDc/I)$. Since this stress should not exceed the allowable stress, the load must be less than the load permissible in a short compression member.

A formula for slender columns was derived in 1757 by Euler: The greatest load that a slender column of length $L$ will carry is $P = EA/(L/r)^2$, in which $A$ is the cross-sectional area of the column, and $r$ is the least radius of gyration of the cross section. The quantity $L/r$ is called the slenderness ratio. It will be seen that the load decreases rapidly as the slenderness of the column increases. Euler's formula does not apply to the less slender columns used in building bridges. Such columns are called intermediate columns. No exact analysis for intermediate columns has been made and designers resort to empirical formulas for determining the allowable load as compared with the load permitted on a short compression member. These column formulas give results that are in agreement with the results of tests made on columns with different slenderness ratios. The three most widely used types of column formulas are: the Rankine formula, proposed about 1860 by J. M. Rankine, of the University of Glasgow; the straight-line formula, proposed by T. H. Johnson in 1884; and the parabolic formula, proposed by J. B. Johnson in 1882.

Many formulas of each of these types have been used. As examples, three formulas that have been widely used for the design of structural steel columns in building frames are given below:

Rankine, $$\frac{P}{A} = \frac{1800}{1 + \dfrac{(L/r)^2}{18{,}000}}.$$

Straight line, $$\frac{P}{A} = 16{,}000 - 70L/r.$$

Parabolic, $$\frac{P}{A} = 17{,}000 - .485\,(L/r)^2.$$

In each of these formulas, $P$ is the allowable load, $A$ is the area of the cross section in square inches, $L$ is the unsupported length of the column in inches, and $r$ is the radius of gyration of the cross section, a quantity closely related to $I$, the moment of inertia of the cross section used in the flexure formula.

To illustrate the use of a column formula, let the parabolic formula given above be used to find the allowable end load on a structural steel column of round cross section, 3 in. in diameter, in two cases: (1) the length is 45 in., and (2) the length is 90 in. For a solid, circular cross section, $r$, the radius of gyration is one-fourth of the diameter, or in this example $r = \frac{3}{4}$ in. The area of the cross section is $1.5^2\pi = 7.07$ sq. in. For case (1), $L/r$ is therefore $45/0.75 = 60.$, and, for case (2), $L/r = 120$. Making these substitutions in the formulas:

(1) $P/A = 17{,}000 - .485 \times 60^2 = 15{,}255$ lb. per sq. in.
$P = 15{,}255 \times 7.07 = 108{,}000$ lb.

(2) $P/A = 17{,}000 - .485 \times 120^2 = 10{,}000$ lb. per sq. in.
$P = 10{,}000 \times 7.07 = 70{,}700$ lb.

The allowable load on the more slender column is much less.

Eccentrically-located columns often occur in structures. A theoretically correct analysis of such columns exists and results in the secant formula. Because the use of this formula is laborious, empirical methods giving good results are often used.

## COMBINED STRESSES

There are cases in which the unit stress at a point on a certain plane in a stressed body as calculated by the ordinary formulas is not the greatest unit stress at that point; a greater unit stress exists on some other plane. The relationships between the unit stresses on different planes at a point are important. The term combined stresses is sometimes used to denote the part of the mechanics of materials that treats of these relationships.

**Stress Relationships.** The state of stress at a point in a stressed body may be completely represented by showing the stresses that act on the faces of a cube at that point. The common cases, such as those already discussed, are biaxial stress with no stresses on two opposite faces of the cube. At the same point in the same stressed body, the values of the unit stresses will be different on differently inclined planes. By use of the principles of statics, many important relationships may be derived. Three of these are as follows:

1. If shearing unit stress exists at a point on a given plane, there is an equal shearing unit stress on the plane perpendicular to the given plane at the same point.

2. There is a certain plane on which the normal unit stress is greater than on any other plane.

3. On the plane perpendicular to this plane, the normal unit stress is less than it is on any other plane. The maximum and minimum normal stresses referred to in (2) and (3) are called the principal stresses and the planes on which they act are called the principal planes.

In ordinary design procedure it is rarely necessary to calculate the principal stresses by the methods just given because the simple formulas in common use give maximum stresses in most cases. Combined stresses must be used, however, in many problems such as designing a shaft subject to both torsion and bending moment.

## ADVANCED PROBLEMS

Numerous problems other than those mentioned are within the scope of strength of materials. Many of these are regarded as advanced problems. In the cases so far mentioned, the stress is either treated as uniformly distributed, or the stress at a point in a cross section is assumed to be proportional to the distance of the point from an axis where the stress is zero. There are many cases of stress varying in a more complex way. Such cases are commonly regarded as advanced problems outside the field of elementary strength of materials.

Common examples of nonlinear stress variation include: curved beams, thick cylinders subject to internal or external pressure, shafting with noncircular cross sections, and loaded bodies in which there are abrupt changes in cross section, such as grooves, notches, holes or fillets. The stressed bodies considered so far were assumed to be loaded with static loads, gradually applied or gradually removed. Variable or fluctuating loads, if repeated millions of times, may cause failure even though the stresses are somewhat less than the strength of the material. Such failures are called fatigue failures, and the problem of avoiding them is of great importance because of the wide use of high speed machinery. *See also* Elasticity; Engineering Materials; Statics; Structure Analysis. P. G. L.

**STREPSIPTERA** [strɛpsɪ′ptərə], both the scientific and common name of a peculiar group of small insects which form an order of the same name. They are mostly parasitic on bugs, bees, wasps, and Orthoptera. They are closely related to the beetles. The females are thin skinned, cylindrical or flattened, and never leave the body of their host. The males have multifolded wings that fit under the small wing covers: they locate and fertilize the females within the body of the host. The very numerous primary larvae are very active and escape from the body of the mother to that of the host, and thence to flowers or to the ground. They then attach themselves to a new host and bore into it, or, in the case of bees and wasps, are carried to the bee's nest where they attack the bee larvae. Once inside the host, the larvae molt and then look like tiny white grubs. The adult males live only two or three days. C. H. Cu.

**STREPTOMYCIN.** *See* Antibiotics.

**STREPTOSOLEN** [strɛptoso′lən], an evergreen shrub of the potato family represented by one species, *S. jamesonii*, a native of Colombia and Ecuador. It has showy orange flowers, growing 4 to 6 ft. high, and is hardy as far north as San Francisco, California. L. de F.

**STRESEMANN, GUSTAV** [shtre′zəmɑn] (1878-1929), German statesman, was born May 10, 1878, in Berlin. He was educated at the Universities of Berlin and Leipzig, specializing in philosophy, political science, and economics. Stresemann early showed signs of organizing ability, and at the age of twenty-three became secretary of the Union of Saxon Chocolate Manufacturers. Two years later he helped found the League of Saxon Manufacturers, whose purpose it was to organize and improve the local industries.

As a member of the National Liberal Party, Stresemann was elected to the Reichstag in 1907. Ten years later, on the death of Ernst Bassermann, he became head of the party, which included such leading industrialists as Hugo Stinnes. During World War I, Stresemann repeatedly attacked Chancellor Theobald von Bethmann-Hollweg for his weak policies and clamored for a more vigorous prosecution of the war. In 1918 he reorganized his following as the German People's Party which, although monarchistic in sympathies, was ready to support the republic in the interests of peace, national unity, and good business. At the Weimar Assembly of 1919 he voted against the acceptance of the Peace Treaty. In August 1923 Stresemann succeeded Wilhelm Cuno as chancellor. The assignment was most difficult, since Germany at the time was seething with internal disorders, particularly in Bavaria, Saxony, and Thuringia; and the Franco-Belgian occupation of the Ruhr created further problems. Within less than fifteen weeks the government fell, to be succeeded by a new one under Dr. Wilhelm Marx. Stresemann, however, became foreign minister in the new cabinet. He retained this portfolio under all successive ministries until his death in Berlin, Oct. 3, 1929.

Stresemann's accomplishments as foreign minister established his pre-eminence among Germany's post-war statesmen. He discontinued the policy of passive resistance against the French and Belgians in the Ruhr; he was to a large extent responsible for the adoption of the Experts' or Dawes Plan for reparations, with its resultant loan to Germany and evacuation of the Ruhr; he took a leading part in the negotiation of the Locarno Treaties, 1925; he signed a treaty with Russia June 29, 1926; he labored for the admission of Germany into the League of Nations, 1926; he welcomed the opportunity to bring about German adherence to the Kellogg Pact; he fought for the acceptance of the Young Plan for reparations in 1929; and he secured a promise from the Allies that the Rhineland would early be evacuated. Stresemann was also in favor of Aristide Briand's plan for Pan-Europa. It was due largely to Stresemann's gifted oratory and his personal charm that friendly relations were so soon re-established between Germany and the former Allies. In 1926 he, together with Briand and Sir Joseph Austen Chamberlain, won recognition for their services in the cause of world peace by being awarded the Nobel Peace Prize. He died at Berlin Oct. 3, 1929. R. H. L.

**STRETHER, LEWIS LAMBERT** [strɛ′thər], the "observer" and principal character in the novel *The Ambassadors* (1903), by Henry James. Strether's consciousness of his world is the center of interest of the work. W. Y. T.

**STRETTO** [strɛ′tto], a term in music to designate the concluding section of a fugue, in which the subject is imitated in the different parts with much overlapping and dovetailing and a consequent increase in excitement and intensity. The term is also used to refer to the conclusion of non-fugal pieces, in which a similar heightening of intensity is achieved by accelerating the tempo and breaking up the rhythmic patterns into quicker figures in a process known as "diminution." W. Li.

**STREUVELS, STIJN** [strö′vəls] (1871- ), Belgian novelist, whose real name was Frank Lateur, was born at Heule on Oct. 4, 1871. He was a cousin of the poet Guido Gezelle. While working at a village bakery, Streuvels avidly read Scandinavian and Russian writers in translation and, influenced by them, began his literary career with a series of short stories about the peasant life of Flanders.

The pessimistic undertones of Streuvels' tales were quite new in a literature which until then had depicted rural life in roseate colors. Their literary quality also was surprising; Streuvels from the outset showed a true sense of epic grandeur. In his tales, men and women are represented as the victims of elementary forces; the climate and the scenery have an active role in the proceedings. Nature exists for Streuvels as actively and vividly as do his personages. There is a Biblical, a Homeric simplicity in his stories, which is sometimes reminiscent of the works of Maxim Gorky and of Knut Hamsun, but, indeed, as a writer Streuvels is as Flemish and as natural as the Flemish earth. His attempts at deeper psychological insight may have failed in some of his works, but he proved himself a remarkable analyst of the souls of children. The highlights of his work are *De Vlaschaard* (1907) ("The Flax Field"), which depicts a familiar tragedy on a

farm, and *Leven en Dood in den Ast,* a shorter story, which may well be his masterpiece. *Langs de Wegen* (1902) was translated into English as *The Path of Life* (1915). His *Collected Works* were published in 1952-1954. Though his work is largely concerned with the depressed classes of rural Flanders, its social implications are implicit rather than explicit, epic rather than sociological. J. A. G.

**STRIKES.** *See* LABOR PRACTICES AND EMPLOYMENT (*Nature of Labor Disputes*).

**STRINDBERG, AUGUST** [strĭ'nbæry] (1849-1912), Swedish author and dramatist, was born on Jan. 22, 1849, in Stockholm, where his father was a merchant. His childhood

AUGUST STRINDBERG

BROWN BROTHERS

was unhappy, and when he finished his schooling he had to provide for himself. Restless and without means, and cherishing a desire to be an artist and an actor, he planned for a career in various fields. He studied for some time for a philosophical degree, turned to the study of medicine, and before the age of twenty he had some experience as a teacher and a writer. His early religious interests were affected by his admiration of the American Unitarian minister, Theodore Parker, and he became a free thinker; the influence of H. T. Buckle, the English historian, helped to make him a materialist.

The first important product of Strindberg's literary career was a historical drama, *Mäster Olof* (1878; Eng. tr. *Master Olof,* 1915). The background of the play is well painted, but the author's plan was merely to show that all theories have only a limited validity—that what is true today is a lie tomorrow. *Mäster Olof* was not at first a great success, but when Strindberg published his novel *Röda rummet* (1879; *The Red Room,* 1913), he met with real recognition. This was the first great social novel in Swedish literature, and the author was regarded as the leader of a new naturalistic school. He held a position at the Royal Library and married the actress Siri von Essen; but the criticism that his novel received in the conservative press strengthened his feeling that he was essentially a rebel against the established order. In 1882 he published *Det nya riket* ("The New State"), a satire on the Swedish society of his time, and he expressed his ideas also in several plays and a collection of historical novels, among them *Svenska öden och äventyr* (1882; "Swedish Destinies and Adventures").

In 1883, Strindberg left Sweden, and for a time he settled down with his family, first in France and then in Switzerland. In Switzerland he met some Russian political exiles and became more interested than before in social problems. His own marriage experiences provided the background for a collection of short stories in which he opposed the emancipation of women (*Gittas,* 1884; *Married,* 1913). Because of a disrespectful reference to the Lord's Supper in one of these stories he was prosecuted for blasphemy and, although he was acquitted, the episode seems to have been too much for his vivid temperament. He developed a persecution mania, and in the following years he verged on insanity.

After the publication in 1884 of *Utopier i verkligheten* ("Utopias Realized"), which contained fictional discussions of social and economic problems, Strindberg devoted himself for the next five years chiefly to the writing of novels and short stories. In some of these, especially in *Hemsöborna* (1887; "The People of Hemso") and Skärkarlsliv (1888; "Skerry Life"), Swedish nature and folk life are superbly portrayed. He also wrote several naturalistic dramas, among them *Fadern* (1887; *The Father,* 1899), and *Fröken Julie* (1888; *Miss Julia,* 1912; *Miss Julie,* 1914). Strindberg's domestic difficulties, which are echoed in these plays, resulted in his divorce in 1891. He married again, but his second marriage, to Frida Uhl, was of short duration. He occupied himself mainly with a study of the sciences, including alchemy, and in the closing years of the century he passed through a religious crisis, which he depicted in *Inferno* (1897); *Legender* (1898; "Legends"), and *Till Damaskus* (1898-1904; "To Damascus").

Strindberg's last and most productive period began with the composition of *Till Damaskus.* He married for a third time, but this union, with Harriet Bosse, was brief also. Among his important works of this period are several novels and the dramas *Gustaf Vasa* (1899); *Påsk* (1901; "Easter"); *Dödsdansen* (1901; "The Dance of Death"); and *Kronbruden* (1902; "The Crowned Bride"). He supported a theatre, the "Intima teatern," which specialized in his plays, and he contributed numerous comments on current political problems to the press. On May 14, 1912, he died of cancer in Stockholm.

Strindberg is one of the most colorful personalities in Swedish literature. All the ideas of his generation—social, religious, and political—became his personal problems, which he felt obliged to discuss simply because he had never been able to solve them. As a novelist, as well as playwright, he introduced a new period in Swedish literature, and as a master of style he is unsurpassed. The importance of his work has been variously assessed, but present-day historians of literature seem to agree that it constitutes, as a whole, the finest contribution to Swedish national literature in the nineteenth and early twentieth centuries. A. Wi.

**STRITCH, SAMUEL** (1887- ), Cardinal Priest, Archbishop of Chicago, was born Aug. 17, 1887, at Nashville, Tenn., the son of Garrett and Katherine (Malley) Stritch. Educated at St. Gregory's Preparatory Seminary, Cincinnati, Ohio, and at the North American College in Rome, he was ordained a priest May 21, 1909, in Rome by Pietro Cardinal Respighi, vicar general of Pius X. Engaged in pastor work in the diocese of Nashville, 1910-1917, and Chancellor of the diocese, 1917-1921, he was appointed Bishop of Toledo, Aug. 10, 1921, and consecrated there on Nov. 30, 1921. Promoted to the metropolitan see of Milwaukee on Aug. 26, 1930, and transferred to the metropolitan see of Chicago on Jan. 5, 1940, he was raised to the cardinalate on Feb. 21, 1946. W. C.

**STROBILANTHES** [strɒbɪla′nthiz], a group of herbs and small shrubs, cultivated under glass in temperate regions for their bloom and foliage. These plants are sometimes known under the name "conehead." They are native to the India-Burma region where they grow to about 3 ft. high.

J. C. Wis.

**STROMBOLI** [stro′mboli], one of the volcanic islands of the Lipari or Aeolian group, lying off the northeast coast of Sicily. About 5 sq. mi. in area, Stromboli owes its Greek name of Strongyle to its round shape, and it is easily recognizable by its conical form, a clear indication of its volcanic nature. The highest peaks, Serra Vancura and La Cima, which reach an altitude of over 3,000 ft., are the remnants of the old crater, now inactive and crumbling. The area of the continually active craters is located directly northwest of those peaks, at an altitude of some 2,300 ft. The main product of the island is the wine called mavasia. Other occupations are fishing and sailing. Communications with Sicily and with the Italian mainland are assured by a steamship service connecting Lipari and Stromboli with Messina and Naples. The population is mostly grouped in the villages of Stromboli (formerly San Vincenzo), San Bartolomeo, and Ginostra. Pop. 915. *See also* LIPARI.

L. J. W.

**STRONTIANITE** [strɒ′nshənait], naturally occurring strontium carbonate, $SrCO_3$. It is usually white or gray and fibrous. The specific gravity is 3.7, which is high for a nonmetallic mineral. Strontianite gives the red flame of strontium before the blowpipe and is soluble in powdered form with effervescence in dilute acid. It occurs in shallow veins of either ground-water or hydrothermal origin. Strontianite may also be formed by the alteration of the sulphate, celestite. It has been mined in Westfalia, Germany, as a source of strontium.

K. K. L.

**STRONTIUM** [strɒ′nshiəm], symbol Sr., atomic number 38, at. wt. 87.63, density 2.54, m.p. 800° C., b.p. 1,150° C. Strontium, named after Strontian, a town in Scotland, is the central member of the triad which includes calcium and barium. Strontium is a typical member of the alkali earth family in Group II-A of the periodic table. Its atom contains four completed shells of electrons (2, 8, 18, 8) and an outermost shell containing 2 valence electrons. Strontium is always bivalent and strikingly intermediate between calcium and barium in its physical and chemical properties.

Strontium metal, first prepared by Humphry Davy in 1807, is almost a curiosity. It is white, sometimes showing a faint yellow tint, malleable and ductile; it tarnishes quickly in air and takes fire from friction. It decomposes water and alcohol.

**Occurrence.** Strontium minerals are mainly the carbonate (strontianite, $SrCO_3$) and the sulphate (celestite, $SrSO_4$). Deposits of strontium minerals are reported from California, Washington, Arizona, and Texas. Imports are chiefly from Mexico, Spain, and England.

**Principal Compounds and Uses.** Strontium compounds are similar to those of calcium and are prepared by the same methods. The bromide $SrBr_2 \cdot 6H_2O$ forms colorless, deliquescent crystals, readily soluble in water, giving a bitter, salty neutral solution used in treating epilepsy, hysteria, insomnia, and convulsions. Strontium chloride, $SrCl_2$, is used in welding fluxes and in salt baths for treating steel. Strontium carbonate, $SrCO_3$, is a white, insoluble powder used in pyrotechnics and the refining of sugar. Strontium chlorate, $Sr(ClO_3)_2$, is a white crystalline salt, readily soluble, used in pyrotechnics. Strontium hydroxide, $Sr(OH)_2$, is moderately soluble in water, forming a very alkaline solution ($p$H about 13.5). It is used sometimes to remove the last amounts of sugar from molasses (Steggen's process); and it is also used in the manufacture of phosphorescent compounds, fluorescent lighting devices, and depilatory preparations. Strontium lactate, $Sr(C_3H_5O_3)_2 \cdot 3H_2O$, a white crystalline powder, difficultly soluble, is used as a mild antiseptic, antipyretic, and analgesic. Strontium nitrate, $Sr(NO_3)_2$, is a white powder, readily soluble, giving a neutral solution. It is used in pyrotechnics, signal fires, and similar applications. Other uses of strontium are in the removal of iron and magnanese in the purification of caustic soda; and in the production of enamels, glazes, and glass.

B. S. H.

**STROPHANTHUS** [strofa′nthəs], a genus of the dogbane family, made up of about 30 species of trees and shrubs native to Africa and Asia. The climbing South African species, *S. hispidus,* yields seeds from which the glucoside strophanthin is made. It is used like digitalis in treating heart disturbances, particularly those accompanying certain forms of goiter. Some African tribes use these seeds to make arrow poison.

J. A. Bo.

**STROUDSBURG** [strau′dzbɜrg], an industrial borough and summer resort in eastern Pennsylvania, the county seat of Monroe Co. It is situated in the foothills of the Pocono Mts., about 3 mi. west of the Delaware Water Gap and the New Jersey border, and 40 mi. southeast of Scranton. The surrounding area is one of diversified farming. Coal and clay are natural resources. In 1776, on the site of the borough, Colonel Jacob Stroud built a stockade which two years later became a refuge for survivors of the Wyoming Massacre. Stroudsburg was founded in 1806. It has the mayor-council form of government. Transportation is provided by the Delaware, Lackawanna and Western and the Pennsylvania railroads. Manufactures include galvanized products, telephone-line equipment, septic tanks, boilers, mowers, rayon, silk, hosiery, hoists, glass, beverages, and cheese. Severe flood damage in August 1955 seriously affected these industries. Pop. 1950, 6,361.

**STROZZI, BERNARDO** [strɔ′ttsi] (1581-1644), Italian painter, was born in Genoa in 1581. He took the vows of the Capuchin Order but was later released and in 1630 went to Venice, where he remained until his death on Aug. 2, 1644. Through contact with the art of Caravaggio and of Rubens, who were in Genoa in 1605 and 1607 respectively, and of the earlier Venetians, Strozzi broke with the Mannerism of his early style and developed the rich colorism which is his distinctive quality. In his figure types, which are vigorously modeled and heavily draped, he belongs to the Baroque period; in technical bravura and chromatic mastery, exemplified by his *Rape of Europe* (Posen Museum) and *St. Sebastian* (San Benedetto, Venice), he contributed, with Domenico Fetti and Jan Lys, to the revitalization of the Venetian tradition after its Manneristic decline.

M. C.

**STRUCTURAL ENGINEERING.** *See* BRIDGES; BUILDING CONSTRUCTION; STRUCTURE ANALYSIS.

**STRUCTURALISM,** a system of psychology which sought to investigate and to describe the composition and integration of experience. It was established, principally by Edward Bradford Titchener, during the last decade of the nineteenth century in opposition to functionalism. Titchener's formulation rested upon his ideas of what science is and

what it attempts to do. He held that the objects of science were facts, that its aim was to understand, and that the attitude of the man of science was disinterested and impersonal. Value and use were consequently taboo in structuralism, as were also the interested and personal attitudes of common sense and technology. Titchener held that the subject matter, problem, and method of all the sciences, including psychology, was the same: the subject matter being the world of experience; the problem, description and explanation; and the method, observation. He differentiated the sciences by point of view. Structuralism undertook to describe and to explain the world of experience from the point of view of the experiencing individual.

Among the various methods employed was introspection—a looking-within at the existing facts of experience. Every available method was used to achieve the ends of description and explanation. Introspection was, however, the chief method of structuralism, and it was used so consistently that the school is sometimes referred to, though incorrectly, as "introspectionism."

The first task of psychology from the structural point of view was to analyze experience into its elementary processes. Of the many elements proposed by various investigators—affection, conation, form quality, image, relation, thought, and sensation—Titchener settled on three: sensation, image, and affection. The others listed could, he believed, be reduced under ultimate analysis to one or another of those selected. He thought, moreover, that if there were any change in the future it would "come by way of addition and not of subtraction." The elements were defined by the enumeration of their attributes—moments, aspects, dimensions, ways in which they could be separately observed. There was, however, no more agreement in psychology about the attributes of the elements than about the elements themselves. Relying upon the two criteria of inseparability (the annihilation of any member of an attributive group annihilates the entire group) and independent variability (variation with limits of one attribute without disturbing the others), Titchener found that every sensation possessed the four attributes of quality, intensity, clearness, and duration, and that vision and pressure possessed the fifth attribute of extent. He also found that images possessed the same attributes as sensation and that affection possessed quality, intensity, and duration. The sensory processes were divided upon the basis of their qualitative resemblance into modalities—discrete qualitative continua.

At a higher level of integration he considered: (1) recognition, direct apprehension, and the perception of the strange or new—complexes based on perception but differentiated by integral feelings and enriched by integrated ideas; (2) memory, recall, and imagination—complexes based on idea but again differentiated by feeling and contributed to slightly by perception; and (3) emotion—based on feeling but contributed to in varying measure by perception and idea. From this level he passed to action, thought, and judgment, and finally to the integration of the self—the experiencing individual with whom he started.

Structuralism was systematic and experimental from beginning to end, and its concern was the description and explanation of observable facts. About fifteen years after it had decided upon its elements—when it was shown by experiments that sensation and image differed not in kind but only in degree and that there was only a psychophysical difference between them (sensation being aroused by stimuli from without the central nervous system and images from within it)—Titchener dropped image and reduced the elementary processes to sensation and affection. Still later, in 1924, when the affective qualities of pleasantness and unpleasantness seemed to be correlated with bright and dull pressures respectively, he reduced the elements to sensation, and his system passed into the form of "sensationism."

Structuralism was concerned only with observables. Since functions and operations could not be observed, but only inferred, they were excluded from the structuralist's consideration. The distinction between structure and function was, however, "no more than a working schema by which one's present knowledge may be temporarily arranged—a schema to be ruthlessly discarded as soon as a better is proposed."

Structuralism stemmed from Wundt's content psychology, which stood in opposition to Brentano's act psychology (the antecedent of American functionalism). The first, however, to draw the distinction in America between the two points of view was James. In a paper in 1884, he distinguished sharply between the structural and functional aspects of psychology. Titchener was trained in Wundt's laboratory, in which emphasis was placed upon analytical observation and the examination of the elementary processes and modes of connection. Structuralism and functionalism supplemented each other, though each had the underlying conviction that it was itself the main reliance of psychology. When, however, functionalism disappeared from the American scene around 1912, under the impact of behaviorism, structuralism soon followed. By 1918 Titchener had turned to phenomenology and existential psychology, and in 1921 he wrote: "Both functional and structural, as qualifications of psychology, are now obsolete terms." *See also* BEHAVIORISM; EXPERIMENTAL PSYCHOLOGY; FUNCTIONALISM. K. M. D.

**STRUCTURAL LINGUISTICS,** a trend in modern linguistics which had its origin in certain observations by Baudouin de Courtenay and Matteo Bartoli but is based essentially on Ferdinand de Saussure's *Cours de linguistique générale* (1916). It was developed in recent years by the so-called Prague School, a group of linguists led by Roman Jakobson and Prince Nikolai Trubetskoy, and by several American scholars (notably E. A. Speiser, B. Bloch, M. Swadesh).

Structural linguistics is one aspect of synchronic linguistics—that is, the study of language at a given moment in time—as opposed to diachronic linguistics, the study of language from the historical or genetic point of view. Areal linguistics also investigates language synchronically, with reference to its position in space, but structural linguistics considers it as a structure or system, a harmonious and coherent whole, in which every piece is inextricably joined to all the others and cannot be understood separately. Structural linguistics is therefore essentially functional, for its studies how every element of language functions within the whole structure. For example, the meaning of the word *obtain* in English cannot be fully grasped unless due consideration is given to words that are semantically close to it, such as *receive, get,* and others; in French or Italian, languages that have no real equivalent of the verb *get,* the semantic areas of *obtain* (*obtenir, ottenere*) and *receive* (*recevoir, ricévere*) are for that reason wider than in English. Every word, like every linguistic form or sound, is limited, and so defined, by others. Thus the English preterit *I gave* is limited by the other past tenses *I was giving* and *I have given; I gave* differs in meaning from the Italian *diedi,* because the semantic area of *davo* and *stavo dando* is not the same as that of *I was giving,* nor does *ho dato* correspond to *I have given.*

The same limitations apply to the sounds of a language,

for these, when considered from the structural or functional point of view, are differentiated by their opposition to other sounds. Thus, in English, the sound (or, in structural terminology, the phoneme) *n* is opposed to the nasals *m* and *ŋ* because, unlike them, it is a dental; it is likewise opposed to the dentals *t* and *d* because, unlike them, it is a nasal; and these two oppositions delimit or define the phoneme *n*. The dental phoneme *d*, on the other hand, is defined with respect to the dental phoneme *t* by its voiced articulation. In Italian, open *ę* and closed *ẹ* are two different phonemes, for several words are semantically distinguished merely by this opposition (e.g., *pęsca,* "peach," and *pẹsca,* "fishing"; *accętta,* "he accepts," and *accẹtta,* "axe"). In Spanish the same difference between *ę* and *ẹ* also exists, but since it is merely positional and does not characterize a word, two phonemes are not involved. Phonemes are therefore semantic entities, related to man's spiritual life, whereas sounds are mere mechanical products, without any real linguistic importance. Sounds and only sounds are perceptible by phonetic devices; to grasp phonemes, knowledge of the language in question is required.

It follows that while the number of sounds that can be uttered by any speaker is virtually unending, the number of phonemes is usually limited to a range between 20 and 50. As a general rule, alphabets take account of phonemes only, and therefore it is possible for most alphabets to satisfy the needs of speakers with 20 to 30 or 35 signs.

The new structural conception of language requires the use of methods that are quite distinct from those demanded by the old historical conception. For example, in considering the function of the preterit *I saw,* or the function of the *-s* plural in Modern English, the student of structural linguistics is obliged to ignore all questions concerning the origin and development of these forms or sounds in the past. Such problems would only confuse his purpose, for in this investigation he is concerned exclusively with Modern English, and, if possible, with the Modern English of a particular decade or year or month. He must compare the Modern English preterit with all the other modern tenses, and he must study the whole Modern English verbal system, but the Old English and Middle English verbs are not his concern.

Nevertheless, the new structural conception has not failed to exercise a renovating and fecundating influence on historical linguistics. The Neogrammarians of the late nineteenth century used to compare one sound, form, or word of Latin with its Modern Italian counterpart, isolating it from all the rest of the language. This practice has been abandoned, under the impact of structural linguistics, in favor of a comparison between the whole system of Latin and the whole system of Italian. Although there is therefore a sharp separation in method between structural and historical linguistics, there is by no means contradiction. Indeed, Roman Jakobson, the founder of the new method, regards himself as primarily an historian.

An important phenomenon in the field of structural linguistics is the existence of stable and unstable language systems. As in the world of animals or of plants, certain language systems are successful and vital because they are fully harmonious; others, which are less harmonious, are unstable; and no completely absurd system is known to exist. It is obvious that a system that has *k, t, p* and *g, d* should also have a *b* to fill the sixth place, and although such defective systems exist, they are rare and unstable and usually develop a *b* in the course of time. A system that has an *ö* (e.g. German, Norse, and French) usually has an *ü* as well; these two phonemes seem to be vitally linked, and a language that has *ü* but no *ö,* like Ancient Greek, eventually looses its *ü*.

In the application of the structural method to language, at least one reservation needs to be made. Although structuralists frequently speak of "the system" of English, French, or any given language, it should be remembered that every language has at least three systems: the predominant one, the one that is outgrown, and the new one that is developing. Thus, in English, *I love : I loved* exists side by side with *I give : I gave; cat : cats* with *mouse : mice;* and in French, *je chante, tu chantes, il chante,* etc., with *je suis, tu es, il est,* etc. Moreover, if a system were perfectly harmonious and coherent, it would never change, whereas it is known that all languages pass sooner or later from one system to another. The difficulties of the new functional theory are great, but it has made noteworthy progress in the time of a single generation of scholars. G. B.

**STRUCTURE ANALYSIS,** the initial phase in designing structural members, in which all the forces that will act on them are determined.

**Relation of Analysis to Design.** The primary problem of the structural engineer is to proportion and assemble various materials as economically as possible into structural units that will support safely the forces which will act upon these units. A building or a bridge consists of an assembly of basic structural units, such as beams, compression members, and tension members. In designing a bridge, the engineer must first determine the loads or forces and calculate various effects due to them before he can design the units which make up the bridge. For example, if a steel beam is to be designed, the loads and reactions, the shears, and the bending moments must first be determined. If a truss (an assembly of tension and compression members) is wanted, the loads, reactions, and the total forces or stresses in each truss member must first be determined. During this part of the procedure, termed analysis, the beam and the truss exist only as line diagrams.

The next step is to determine proportions and select actual sizes. In doing this, however, the designer does not analyze the stress intensities (in other words, the unit stresses) within the beam or the truss. Maximum unit stresses for a particular material, such as medium carbon steel, are already prescribed in design specifications, as those of the American Institute of Steel Construction for buildings, or those of the American Railway Engineering Association for bridges. With these specifications as a guide, the designer calculates the proportions of a beam or girder, such that the limiting unit stresses will not be exceeded when the maximum shears and the maximum bending moments act at various critical sections.

The reader should keep clearly in mind this distinction between the analysis of line diagrams for the determination of maximum shears or bending moments or total stresses and the actual design, which involves a selection of material and its proportions in accordance with governing specifications.

**Basic Factors in Analysis.** *Equilibrium of Forces.* The most important factor in the analysis of structures is the law of equilibrium of forces. The structural engineer is concerned primarily with structures which are at rest under the action of various forces. Although the forces may be moving loads, such as highway trucks, the structure itself does not move, except that it may vibrate. For a structural unit which exists in one plane and which is loaded in that plane, the forces must consequently be in equilibrium, as expressed

by the following equations of statics for a nonconcurrent force system in one plane; a nonconcurrent force system being defined as one in which the forces do not intersect at a single point:

$$\Sigma F_x = 0 \quad (1)$$
$$\Sigma F_y = 0 \quad (2)$$
$$\Sigma M_{xy} = 0 \quad (3)$$

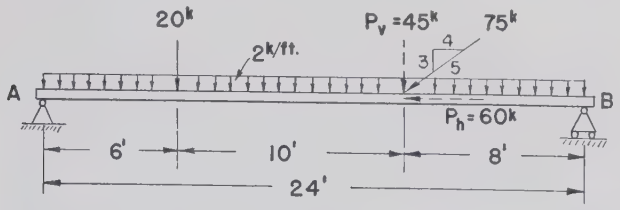
These equations state that the sum of the horizontal force components (1) must balance, that the sum of the vertical force components (2) must balance, and that the sum of the moments of the forces about any point in the plane (3) must balance. When structures are statically determinate, the preceding three equations are sufficient to analyze the effects of force systems.

When there are more than three unknown forces or factors, the structure is said to be statically indeterminate. A structure may be statically indeterminate with respect to the external loads and reactions acting upon it, such as a beam continuous over two spans; or it may be internally statically indeterminate, such as a truss with extra diagonal bars. The analysis of statically determinate units will first be discussed; subsequently the method for treating statically indeterminate structures will be presented.

*Dead Loads and Live Loads.* The loads and forces acting upon structural units may be divided into two general groups, dead loads and live loads. Dead loads are those which are fixed permanently in position. They are often called gravity loads because they act vertically. The weight of a floor slab, beam, or truss or the weights of mechanical equipment fixed permanently in place are considered as dead loads. Live loads, on the other hand, may move on and off a structural unit, or are readily movable. People in a building, trucks on a bridge, furniture in rooms, and snow on the roof are all live loads. The weights of such loads may be readily determined, but there are other types of live loads, such as wind, impact, traction, temperature, and earthquake forces, that cannot be definitely calculated.

## SIMPLE BEAMS AND TRUSSES

**Reactions, Shears, and Moments for Simple Beams.** The effects of loads fixed in position will now be considered. The first step in the analysis of a simple beam is the determination of the reactions due to the loads. In Fig. 1, the reactions (forces) acting at $A$ and $B$, the supports of the beam, are to be found. The loads acting on the beam are given in kips. One kip equals 1,000 lb. The reactions are actually a part of the external load system but they are not known initially. It is necessary to determine the magnitude, direction, and line of action of each reaction in order to define it completely. In the beam there is a frictionless pin at support $A$ and a pin and a rocker at support $B$. The reaction $R_a$, at $A$, must pass through the pin, and consequently the only unknowns here are the direction and the magnitude. Another way of defining these two unknowns is to state that the horizontal and vertical components of $R_a$ are unknown. The reaction $R_b$, at $B$, must pass through the pin at $B$, but it also must be perpendicular to the plane on which the rollers rest. The rollers are assumed to be frictionless, and consequently any force transmitted through them must be perpendicular to the surface on which they roll. Therefore, both the line of action and the direction are known for $R_b$ and the only unknown is the magnitude. The total number of unknowns is three and there are three equations of statics available.



$48 \times \frac{12}{24} = 24^k \uparrow$

$20 \times \frac{18}{24} = 15^k \uparrow$

$45 \times \frac{8}{24} = 15^k \uparrow$

$R_{a_v} = 54^k \uparrow$

$P_h = 60^k \leftarrow$

$R_{a_h} = 60^k \rightarrow$

$48^k \downarrow$

$20^k \downarrow$

$P_v = 45^k \downarrow$

$P = 113^k \downarrow$

$R_{a_v} = 54^k \uparrow$

$R_b = 59^k \uparrow$

*Fig. 1—DETERMINATION OF REACTIONS IN A SIMPLE BEAM*

It will be found convenient to use Equation (3) initially. By taking moments about the pin at $B$, the resulting equation will have only one unknown force, the vertical component of $R_a$, or $R_{a_v}$. Note the calculations in Fig. 1, in which the superscript symbol $^k$ stands for kips. Each load is treated separately, and the moment due to a particular load is immediately divided by the lever arm from $A$ to $B$ in order to get that part of the left reaction due to the particular load under consideration. This method of calculation saves time and reduces the possibility of error by making it easy to calculate mentally the approximate value of the answer. Moreover, it lends itself to a concise arrangement of calculations. After the value of $R_{a_v}$ for each load is thus determined, the results are added algebraically to give the total vertical reaction at $A$.

The reaction at $B$ is determined by using Equation (2) for the equilibrium of vertical forces. The loads acting downward are added, the value of $R_{a_v}$ is subtracted, and the remainder is $R_b$. Finally, from Equation (1), the horizontal component of the reaction at $A$ is obtained.

After the reactions for a given beam have been determined, it is necessary to determine how various internal sections of the beam are affected by the external loads. This requires a determination of shears and bending moments. Note the beam in Fig. 2*a*. The beam as a whole is in equilibrium under the loads and reactions. If the beam is assumed to be cut into two parts, as in Fig 2*b*, without disturbing any of the external or internal forces, each part is also in equilibrium. The internal forces at the cut section must not be overlooked, however, in applying the laws of statics. Actually, the beam is not cut, but in order to aid the analysis of internal effects imaginary sections are passed across the beam, cutting it into free-body diagrams.

There is a shearing effect $V$ on the cut section. Shear is defined as the algebraic summation of the forces parallel to, and on one side of, a section. Note the forces on the left side of section 1. There is a reaction of 45 kips acting upward and a downward load of 40 kips. Hence, $V_1$ equals 5 kips upward on the left side of the section and is defined as positive shear. Note Fig. 2*c*, showing the two free bodies created by passing section 2. The algebraic summation of the loads to the left results in a value of shear equal to 15 kips, downward on the left side of the section; this downward direction defines it as negative shear.

It is not convenient to sketch a large number of diagrams such as those illustrated. It is better to plot a shear diagram

like that in Fig. 2*d* which shows the variation in shear from section to section. Distances along the beam are used as abscissas and the corresponding values of shear as ordinates in this diagram. The shear values are obtained by employing the same mental processes just discussed, but the designer does not stop to construct a large number of individual free-body diagrams.

The forces to the right of any section might just as well have been summed instead of the forces to the left. The answer would be the same. In actual practice it is convenient to sum up the forces on that side of a cut section which can be done most conveniently.

Bending moments and moment diagrams will now be considered. Note Fig. 2*b* again. The magnitude of the bending moment $M$ is wanted at section 1, which is 10 ft. from $A$. The simplest way to define bending moment is to state that it is a force multiplied by a lever arm. If more than one force is being considered, it is the algebraic summation of the values obtained by multiplying each force by its lever arm.

The 45-kip reaction has a lever arm of 10 ft. and produces a moment in a clockwise direction of 45 × 10 or 450 ft.-kips. The 40-kip load has a lever arm of 3 ft. and produces a moment in a counterclockwise direction of 40 × 3 or 120 ft.-kips. The magnitude of the resulting moment is 330 ft.-kips. The sign is positive because it tends to produce clockwise rotation on the right side of the section or to create tension in the bottom fibers in the beam. Another way of defining positive moment is that it tends to sag the beam. Negative moment creates compression along the bottom surface of the beam, tending to hump it. A diving board with a diver at the free end is a good example of a beam under negative bending moment.

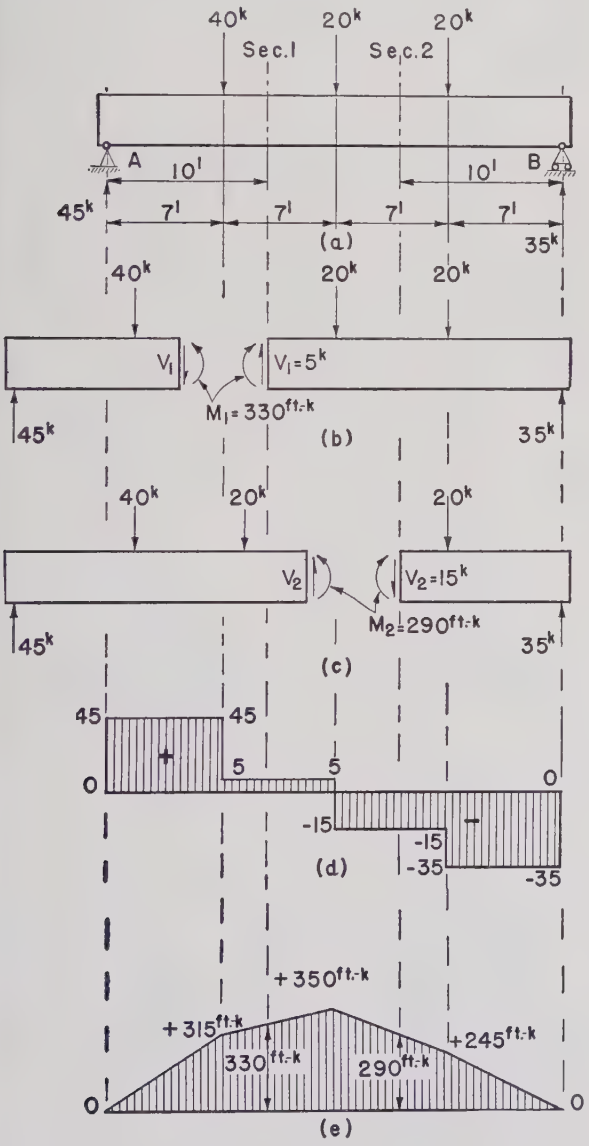


*Fig. 2—DETERMINATION OF SHEARS AND BENDING MOMENTS IN A SIMPLE BEAM*

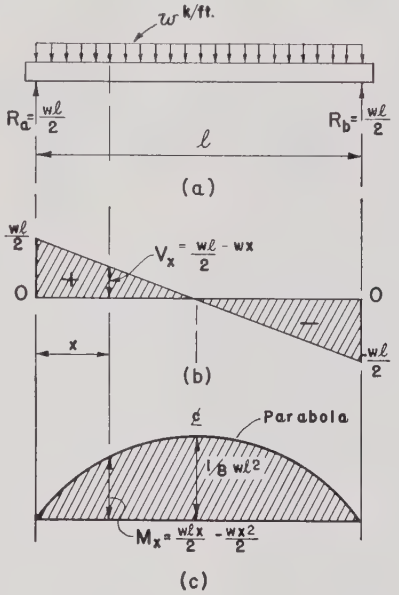

*Fig. 3—ANALYSIS OF A SIMPLE BEAM UNIFORMLY LOADED*

Note section 2 in Fig. 2*c*, 10 ft. from $B$. The bending moment here is 290 ft.-kips. Rather than construct many pictures like Figs. 2*b* and 2*c*, it is more convenient to draw a graph, the bending-moment diagram in Fig. 2*e*. The ordinates give the values of the moments at the various sections of the beam. In this illustration the weight of the beam is neglected.

Figure 2*e* is a characteristic moment diagram for a beam with concentrated loads; it is a series of sloping straight lines. Figure 2*d* is a characteristic shear diagram; it is a series of horizontal lines. Figure 3 shows a simple beam loaded with a uniform load. The moment diagram 3*c* is a parabola; the shear diagram 3*b*, a sloping straight line; and the load diagram 3*a*, a horizontal line.

The slope of the moment curve at a point is the shear at that point. The slope of the shear curve at a point is the load at that point. A point of zero shear is often used to locate the point of maximum moment on a beam.

**Stresses in Simple Trusses.** The simplest truss is a single triangle with three straight bars connected at their ends by frictionless pins and supported as shown in Fig. 4. An inclined load $P$ acting at the upper panel point $U_1$ causes reactions $R_a$ and $R_b$, and develops a stress in each bar with a line of action coinciding with the bar axis. In modern trusses, most joints are riveted or the members are otherwise rigidly connected, as by welding; consequently, the force in a bar will not act exactly in line with the axis. The deviation is so small, however, that in the analysis of trusses it is customary to assume that the position of a member defines the direction and line of action of the stress in that member.

Hence, the only unknown element is the magnitude of the stress.

At this point, the reader should consult Fig. 5 in order to see the distinction between a beam (or plate girder) and a truss. A beam is a solid unit which develops its ability to support loads by its bending resistance and its shear resistance. The truss is an assembly of straight bars joined together in triangular patterns. The loads are resisted by axial forces developed in each bar. In general, trusses are used to carry loads over longer spans than those used for beams and girders.

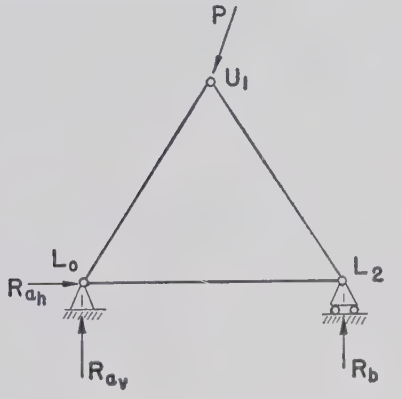

*Fig. 4—ANALYSIS OF A SIMPLE TRUSS*

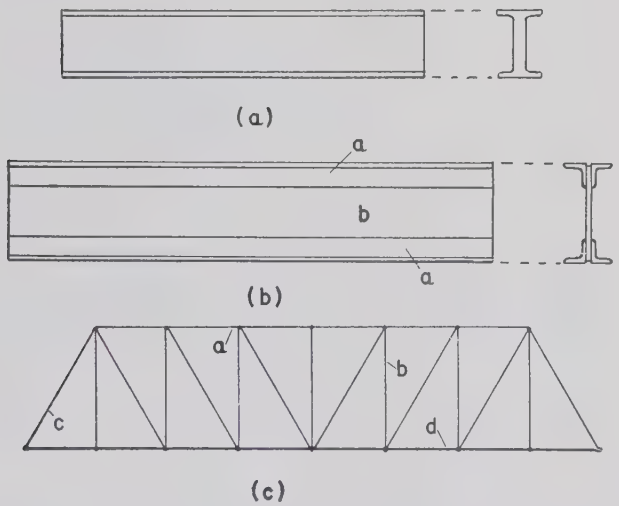

*Fig. 5—DISTINCTION BETWEEN A PLAIN I-BEAM (OR PLATE GIRDER) AND A TRUSS*

*(a) Rolled I-beam; (b) Fabricated plate girder; parts a are flange angles; and part b is the web; (c) Truss; parts shown are: a, top chord; b, vertical; c, diagonal; and d, bottom chord.*

The method of analyzing stresses or forces will now be illustrated by the parallel-chord Pratt truss in Fig. 6*a*. The method of calculating reactions is the same as that used for beams and will not be discussed further. The fundamental equations for the calculation of stresses are the equations of statics, Equations (1), (2), and (3). The procedure of passing sections, cutting bars and internal forces, and separating the truss into free-body diagrams will be used. Sections may be passed in different ways. They may be passed completely around a joint, isolating a concurrent force system, in which the forces intersect at a single point; or they may be passed completely across the truss cutting a nonconcurrent force system, in which the forces do not intersect at a single point. Sections across a truss should not cut more than three unknown bars because only three equations of statics are available.

If the stress in the bottom chord member $L_1L_2$ is wanted, section 1 is passed across the truss, cutting $L_1L_2$ and not more than two additional bars. The left free-body diagram isolated by this section is shown in Fig. 6*b*. Three known external forces are acting on the free body. There are also three unknown forces, $L_1L_2$, $U_1U_2$, and $U_1L_2$. It is not known initially whether they push or pull; in other words, whether they are compression or tension forces.

Equation (3) will be used; and since $L_1L_2$ is wanted, the best selection for the moment center is the intersection of the other two unknown forces at panel point $U_1$. This method eliminates these two unknowns from the equation of moments. The moment of the known external forces about $U_1$ is the reaction of 100 kips multiplied by a lever arm of 24 ft. This tends to revolve the free body with a moment of 2,400 ft.-kips in a clockwise direction around the moment center. The force in the member $L_1L_2$ multiplied by an arm of 32 ft. must supply a balancing moment in a counterclockwise direction of 2,400 ft.-kips. Hence, the stress in $L_1L_2$ equals 2,400/32 or 75 kips. It must be a tension force in order to produce a counterclockwise rotation about $U_1$.

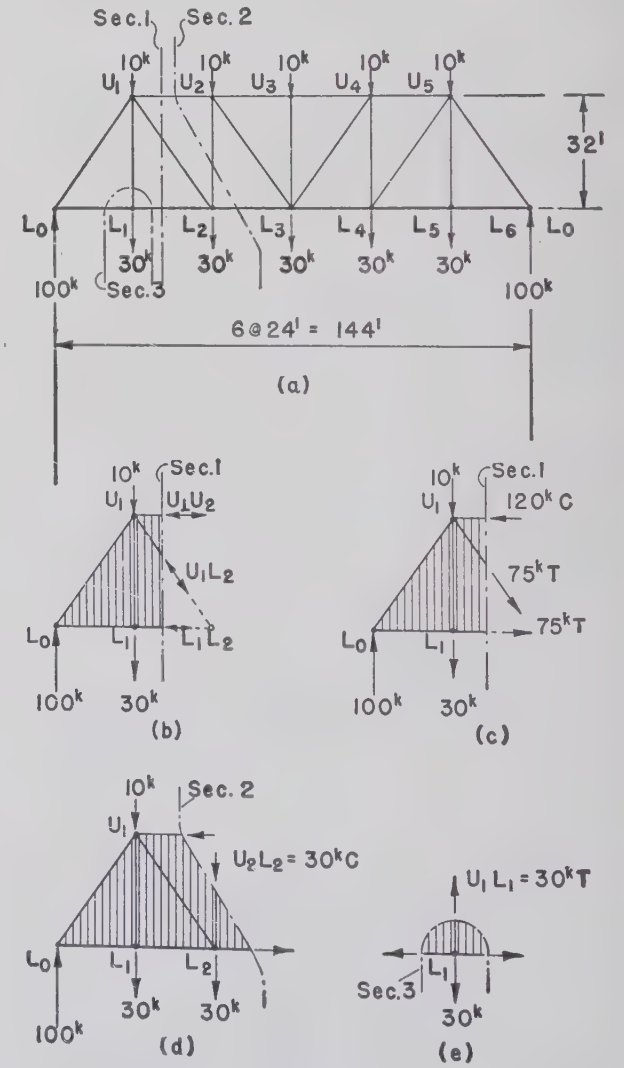

*Fig. 6—DETERMINATION OF STRESSES IN A PARALLEL-CHORD PRATT TRUSS*

Consider the upper chord member $U_1U_2$. It may be determined by taking moments around the panel point $L_2$, the intersection of the other two forces $U_1L_2$ and $L_1L_2$. The moment of the known external forces about this point equals 3,840 ft.-kips, in a clockwise direction. Hence, $U_1U_2$ equals 3,840/32 or 120 kips. The force must push on the cut end of $U_1U_2$ in order to produce a counterclockwise moment and hence is a compression stress.

The same free body is used to get the stress in the diagonal $U_1L_2$. Inasmuch as the upper and lower chords are horizontal, the use of Equation (2) will involve only the unknown force $U_1L_2$. The vertical component of $U_1L_2$ must equal $\Sigma F_y$ of the known external forces acting upon the free body. The total of 60 kips is the reaction of 100 kips upward, minus downward loads of 40 kips. In order to keep the free body from moving upward, the vertical component of $U_1L_2$ must pull downward at the end of the cut bar with a force equal to 60 kips. But the force $U_1L_2$ acts along the inclined axis of the bar and bears the same relation to its vertical component as the length of the bar does to its vertical projection. Consequently, the resultant force is $^{40}/_{32} \times 60$ or 75 kips tension. All the forces acting upon the free body are now determined as shown in Fig. 6*c*.

Sections similar to section 1 may be passed across other panels in order to find the stresses in the remaining bottom chords, top chords, and diagonals.

If the stress in a vertical member $U_2L_2$ is desired, section 2 is passed as shown in Fig. 6*d*. The section is inclined as shown in order to cut not more than three bars. Since the forces in the top and bottom chords cut by this section act along horizontal lines, it is advisable to use the second equation of statics for the bar $U_2L_2$. The resulting equation will then have only one unknown. $\Sigma F_y$ on the free body equals 30 kips acting upward. Hence the stress in $U_2L_2$ is 30 kips acting downward or pushing on the end of the cut bar, thus indicating compression.

The method of obtaining the stress in the vertical member $U_1L_1$ is illustrated in Fig. 6*e*. An inspection of the lower end of $U_1L_1$ shows no inclined diagonals intersecting at joint $L_1$. The only member which can resist vertical forces at that joint is $U_1L_1$. Hence it is convenient to pass a section around the joint $L_1$ isolating a concurrent force system. Equation (2) applied to the system results in a value of 30 kips for $U_1L_1$ acting upward. It pulls on the joint; it is a tensile force.

The preceding illustration of the analysis of truss stresses demonstrates the fundamental procedure. The experienced analyst does not usually take time to draw the free-body diagrams; nevertheless he has them in mind as he calculates the stresses in any type of truss. There are particular arrangements of calculations which greatly facilitate the work involved. Moreover, graphical methods instead of algebraic methods are often used.

**Live Loads and Influence Diagrams.** Influence diagrams are graphs that show the variation in effect at a definite section of a beam or truss due to a single unit load moving across a span. Their primary purpose is to guide the placing of a system of moving loads in order to cause the maximum effect at a particular section. The methods of calculating shears and moments due to loads fixed in position have already been presented. The same procedures are used in obtaining the effects of live loads for any position that they may occupy momentarily in crossing a span. Hence, the basic problem which distinguishes the treatment of live loads from that of dead loads is to find the governing position of the live loads for a particular section. In Fig. 7*a* the position of the crane wheels shown will cause maximum shear at section *d-d* of the beam. A different position as shown in Fig. 7*b* will cause maximum moment at section *d-d*. When another section is studied, two entirely different load positions will cause the maximum shear and the maximum moment.

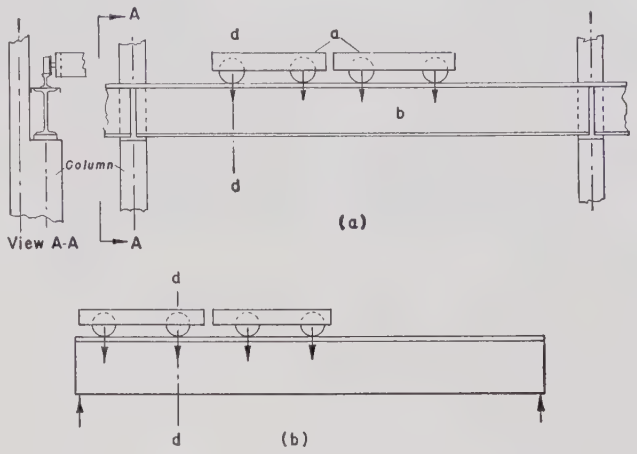

*Fig. 7—FINDING GOVERNING POSITION OF LIVE LOADS*
*In diagram (a), a refers to the moving crane; b, to the crane girder.*

Figure 8 shows typical influence diagrams for the left reaction of a beam, for the shear at section *c*, and for the moment at section *d*. The ordinates of these diagrams give the magnitude of the particular effect at the particular section when the unit load on the beam is vertically in line with the ordinate. All ordinates of the influence diagram for $R_a$ in Fig. 8*b* are positive, thus indicating that a load anywhere on the beam produces an upward reaction at *A*. The diagram suggests that a moving truck, if it crosses the span, should be placed at the left end with the biggest

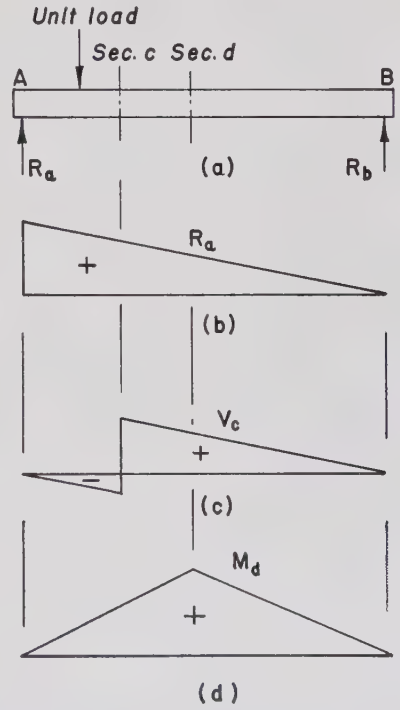

*Fig. 8—TYPICAL INFLUENCE DIAGRAMS FOR A BEAM*

wheel load above the largest influence ordinate. If a moving uniform load acts on the beam, the entire span must be loaded in order to obtain the maximum reaction.

The influence diagram for shear in Fig. 8*c* is partly negative and partly positive. It indicates that the maximum positive shear due to a truck will be caused by placing the truck just to the right of section *c*, with the biggest wheel load at the section. When a moving uniform load

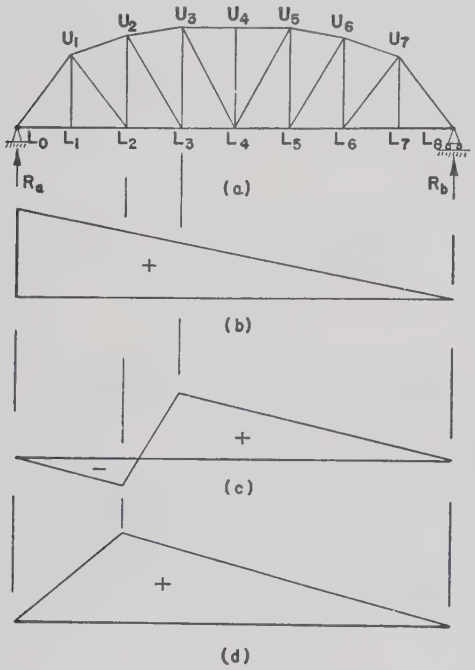

*Fig. 9—TYPICAL INFLUENCE LINES FOR A TRUSS (a) Arrangement of truss; (b) Influence line for reaction* $R_a$*; (c) Influence line for stress in* $U_2\ L_3$*; (d) Influence line for stress in* $L_2\ L_3$

is being considered, only that part of the span between section *c* and the right support *B* should be loaded in order to create maximum positive shear. The influence line for moment at section *d* is shown in Fig. 8*d*.

Figure 9 shows typical influence lines for a truss reaction, for stress in the bottom chord $L_2L_3$, and for stress in the diagonal $U_2L_3$. These lines serve to guide the placing of live loads causing maximum stresses in the particular bars to which they apply. They may also be used to get the final stress in a bar due to a system of loads by multiplying each load by the influence ordinate below the load, and then adding the products to get the total stress.

There are established rules and equations which greatly facilitate the work of the designer in obtaining critical positions for a series of concentrated loads such as those from the wheels of a locomotive; these are detailed in textbooks on the subject.

When maximum live-load shears or moments or stresses are determined for various sections, they must be added to the dead-load effects at the same sections in order to obtain the total values that will govern the design of a beam or a truss.

## STATICALLY INDETERMINATE BEAMS

**The Geometry of Slopes and Deflections.** The geometrical relationships associated with the slopes and deflections of the elastic curve of a beam are important factors in all methods of analysis of continuous structures. Figure 10 shows a two-span continuous beam. There are four unknown reaction components and only three equations of statics. Hence, the beam is statically indeterminate to the first degree.

The deflection curve is shown in Fig. 10*b*. The beam is continuous over the center support. The slope of the tangent to the elastic curve at end *B* of span *AB* is the same as the slope of the tangent at end *B* of span *BC*. This condition supplies the extra equation needed to obtain the reactions and subsequently the shear and the bending-moment diagrams in Figs. 10*c* and 10*d*, respectively.

The fourth equation might also be developed from a consideration of the deflection at support *B*. The zero deflection in the continuous beam is a governing condition. If support *B* is removed and the deflection at *B* is calculated for the simple span *AC* due to the load shown, the result must be equal to the upward deflection at *B* caused by the

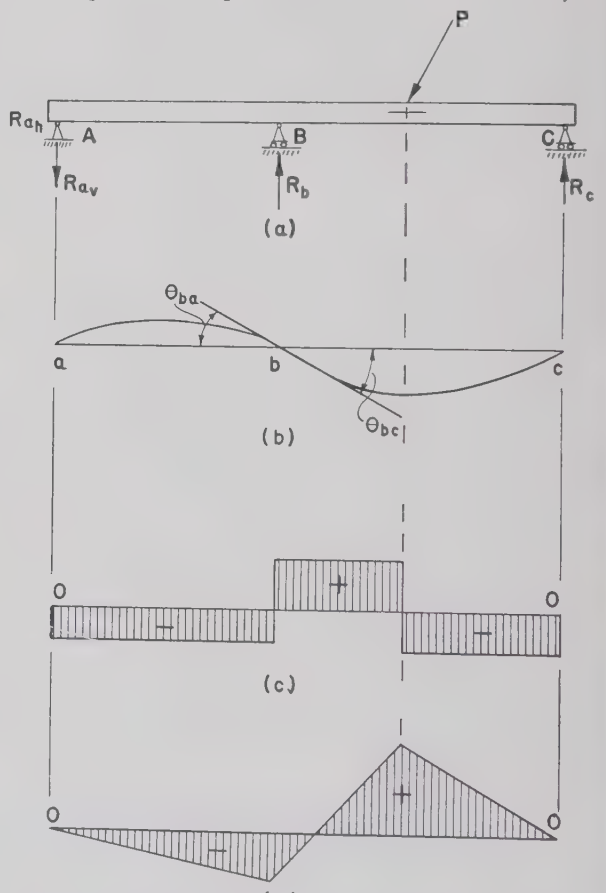

*Fig. 10—DETERMINATION OF THE DEFLECTION CURVE, AND THE SHEAR AND MOMENT DIAGRAMS IN AN INDETERMINATE, TWO-SPAN, CONTINUOUS BEAM* $\theta_{ba}$ *equals* $\theta_{bc}$

replacement of the support or the reaction $R_b$ acting on the simple span *AC*.

Slopes and deflections depend upon the elastic properties of a beam and its loading conditions. They may be quickly obtained from the following moment-area theorems, postulated in 1873 by Professor C. E. Greene:

1. The change in slope between the tangents to the deflection curve of a beam at two points is equal to the area under the *M/EI* curve between the two points.

2. The deflection of any point *B* on the elastic curve of a beam away from the tangent to the curve at point *A* is equal

to the first moment about $B$ of the area under the $M/EI$ curve between the two points.

These theorems lead directly to the auxiliary propositions that the slope of the elastic curve at any point of a simple beam is numerically equal to the shear at the same point due to the $M/EI$ area (from the actual loads) considered as a load on the beam; and the deflection at any point on the beam is numerically equal to the bending moment at the point due to the $M/EI$ area treated as a load. Here, $M$ is the bending moment at any point of the beam due to the actual loads, $E$ is the modulus of elasticity of the material in the beam, and $I$ is the moment of inertia of the cross section of the beam.

**The Moment-Distribution Method.** The moment-distribution method, developed by Professor Hardy Cross of Yale, is probably the most widely used method in the United States for the analysis of continuous beams.

The method starts by making a structure, such as a three-span continuous beam, rigidly fixed at each joint or support and then finding the fixed-end moments for the loading being studied. One joint at a time is then released and the fixed-end moments at that joint are modified until the moments at the joint are balanced. The joint is then fixed temporarily until all other joints have, in succession, been released, balanced, and fixed in their new positions. The procedure is repeated again and again until the desired degree of accuracy is obtained. The process may be vizualized by considering it as a slow-motion picture of the magnified physical response of the structure as it gradually adjusts itself to a load condition which has just been created upon it.

*Fixed-End Moment, Stiffness, and Carry-over Factor.* The fixed-end moment at the end of a particular span is the moment which would exist at that end if it were fixed against rotation. The difference in fixed-end moments at a joint or support is an unbalanced moment; when the joint is released, this moment is distributed to the adjacent members in proportion to their stiffness. Stiffness is defined as the moment necessary to produce unit rotation at one end of the member when the other end is fixed. The rotating end is on unyielding supports. The moment that is distributed to one end of a particular span in proportion to its stiffness causes a moment at the far end of the same span. The ratio of the moment at the far end to the moment at the rotating end is called the carry-over factor.

The fixed-end moment, the stiffness, and the carry-over factor are the three important elements in the process of moment distribution. They are easily derived from the moment-area theorems.

Any case of variable loading on a beam with constant section may be obtained by integrating the expressions for the concentrated load within the proper limits. The stiffness of a beam with constant moment of inertia for its full length is $4EI/L$. The stiffness of a beam with the far end pinned, instead of fixed, is $3EI/L$. Inasmuch as the modulus of elasticity $E$ is usually the same for all spans in a continuous beam, the relative stiffness of each span is $I/L$. The carry-over factor for a beam with constant moment of inertia is $-\frac{1}{2}$.

**Maximum Positive and Negative Moments.** The engineer must design continuous beams for combined dead-load and live-load effects. With influence diagrams as a guide, live loads are placed in different positions to obtain the maximum effects at various sections. From the results of analyses of a number of positions, a series of maximum positive and maximum negative values are obtained and plotted as ordinates along the beam. Envelope curves drawn through these points are termed curves of maximum positive and negative moments.

Initially, values of stiffness are assumed for each span. The first set of maximum moment values are, hence, approximate; they lead to a preliminary design from which more accurate values of stiffness are obtained. The process of calculating maximum moments is then repeated for a final design.

Maximum positive and negative shears and reactions must also be computed before a structure can be completely designed.

**Variable Moment of Inertia.** Most continuous bridges have a changing cross section; consequently, the moment of inertia $I$ in each span is variable rather than constant. The stiffness factors and carry-over factors may be modified considerably for such spans. In fact, if a span is not symmetrical about its center line, the factors at one end will differ from those at the other end. The fixed-end moments will also differ.

There are various methods for calculating the modified factors. Diagrams are also available for certain standardized variations of *I*. *See also* BRIDGES; ELASTICITY; STATICS; STRENGTH OF MATERIALS. H. E. W.

**STRUMA** (Gr. **STRIMÓN**) [stru′mɑ, strimɔ′n], a river, also called the Strymon, rising in the mountains of western Bulgaria, southwest of Sofia, and flowing southward 225 mi. through Macedonian Greece to enter the Gulf of Strimón on the Aegean Sea. It enters Greek Macedonia in the region of the gorge formed by the Belesh Planina and the Perim Dagh of Bulgaria. Near Sérrai, Greece, the Strimón River formerly broadened to form Lake Akhinou, but this lake has been drained and the area is now utilized for the growing of tobacco. The lower Strimón region is quite fertile, producing rice and wine grapes as well as tobacco. S. Van V.

**STRUTHERS** [strʌ′ŧhərz], an industrial city in Mahoning Co., in northeastern Ohio, located 5 mi. southeast of Youngstown. Founded in 1800, the city was incorporated in 1922. The Pennsylvania and the Pittsburgh & Lake Erie railroads provide transportation. The manufacture of steel and its products, such as rods, tubes, and wire, is the most important industry. Pop. 1950, 11,941.

**STRUTT, JOHN WILLIAM (3RD BARON RAYLEIGH)** (1842-1919), English physicist, was born in Essex, England, Nov. 12, 1842. Strutt was educated at Trinity College, Cambridge, and in 1873 succeeded to his father's title. He became professor of experimental physics at Cambridge in 1879 and in 1887 professor of natural philosophy at the Royal Institution. In 1904 he was awarded the Nobel Prize for Physics for the discovery of the element argon, which he isolated in co-operation with Sir William Ramsay, who was awarded the Nobel Prize for Chemistry in recognition of his work on the project. In 1905 Lord Rayleigh became president of the Royal Society and in 1908 was named chancellor of Cambridge University. He died in Essex on June 30, 1919.

The apparent existence of a component of air other than nitrogen and oxygen had been demonstrated in the eighteenth century by Henry Cavendish, who observed that a residue of unknown composition remained after oxygen and nitrogen were removed from the air. In 1892 Lord Rayleigh verified this when, during an investigation of the densities of gases, he discovered that atmospheric nitrogen is heavier than nitrogen prepared by a chemical process. Working from Lord Rayleigh's hypothesis, Sir William Ramsay began

experiments in 1894 involving the combination of nitrogen with heated magnesium. In 1895 Rayleigh and Ramsay jointly issued a paper entitled *Argon, a new constituent of the atmosphere*, which detailed their findings.

Lord Rayleigh had previously postulated electrolytic dissociation in 1884, a year after Svante August Arrhenius published his highly controversial thesis on this subject. He also carried out investigations in optics, on color vision, and in the field of psychical research. Lord Rayleigh received many honors, and held several important offices. H. N. A.

**STRYCHNINE.** *See* PHARMACOLOGY.

**STUART (STEWART or STEUART), HOUSE OF,** a noble family which occupied the thrones of Scotland and England for almost four hundred years. It was founded by Alan of Dol, a Norman baron and a follower of William the Conqueror, from whom he obtained a grant of lands in Shropshire. His nephew, also named Alan, extended the family's holdings when he was given a barony in Suffolk by Henry I of England. His younger son, Walter, established the house in Scotland by entering the service of David I as hereditary steward of the royal household. The line was continued through Walter's great-great-grandson, John, who fought at Falkirk in 1298. Of John's seven sons, the eldest, Alexander, was the forebear of the earls of Angus; the second, Alan, the ancestor of the dukes of Lennox; from the third, Walter, were descended the earls of Galloway; and from the fourth, the earls of Athol, Buchan, and Traquair. John's nephew, Walter, the sixth steward, fought at Bannockburn (1314) and married Marjory, daughter of Robert the Bruce, King of Scotland. Their son, Robert, as regent for David II, was largely responsible for Scotland's recovery from English domination (1338-1341) and succeeded him on the throne in 1371 as Robert II (1371-1390), establishing the Stuarts as royal rulers in Scotland. Others of the Stuart dynasty were James I, famous as a lawmaker and the author of *The Kingis Quair;* James IV, who married Margaret Tudor, eldest daughter of Henry VII of England; and James VI, her grandson and the son of Mary, Queen of Scots, who in 1603 succeeded to the throne of England as James I, thereby uniting the two kingdoms in a dynastic, but not a constitutional union. James's son, Charles I, was executed by the Parliamentarians in 1649, and his children took refuge in exile. However, the Stuarts were restored to power in 1660 in the person of Charles II, but in 1688 his brother and successor, James II, a supporter of the Roman Catholics, was deposed by the nobles of England in favor of his son-in-law William of Orange. Although James fled to France and exile, his two daughters, Mary (1662-1694), wife of William III, and Anne (1665-1714), ruled as queens of England. James II's son, James Francis Edward (1688-1766), the Old Pretender, and his grandson, Charles Edward (1720-1788), the Young Pretender, both claimed the throne of England and led unsuccessful revolts, known as the Fifteen (1715) and the Forty-five (1745), to obtain it. The last legitimate descendant of the Stuarts in the male line, Henry, Cardinal York, a younger son of the Old Pretender, died in Rome in 1807. Several descendants in the female line are living in the twentieth century. A. Jo.

**STUART, LADY ARABELLA** (1575-1615), daughter of Charles Stuart, Earl of Lennox, was next in line after James VI of Scotland, her cousin, to the throne of Queen Elizabeth of England. She was involved in intrigues planned by those who did not want James to succeed Elizabeth. The English queen therefore kept her under close guard. After James succeeded Elizabeth as James I of England in 1603, Lady Arabella professed her loyalty to him, although plots aimed at placing her on the throne continued. In 1610 she secretly married William Seymour, who also had a claim to the throne. They were at once imprisoned but both later escaped. Lady Arabella was recaptured and spent the rest of her life in the Tower of London, where she died, insane, Sept. 25, 1615. E. R. A.

**STUART, GILBERT** (1755-1828), American portrait painter, was born in North Kingston Township, R. I., Dec. 3, 1755. He first studied under the Scottish painter Cosmo Alexander, in Newport, later spending five years as a pupil of Benjamin West in London and twelve years as a successful portrait painter there and in Ireland. By 1793 Stuart had returned to America, and between 1794 and 1796 he painted the portraits of George Washington that have become Stuart's best-known works and the most generally accepted likenesses of Washington; these include the bust-length "Vaughan" and "Atheneum" types and the full-length "Lansdowne" type. Stuart later painted many replicas of these, as well as portraits of other distinguished persons in Philadelphia, Washington, and Boston, where he spent his later years. His finest portraits are characterized by incisive modeling, especially in the faces, vigorous brushwork, and the use of unifying glazes. Among his works are portraits of John Adams, Thomas Jefferson, James Madison, James Monroe, and John Quincy Adams. He died in Boston on July 27, 1828. E. B. S.

**STUART, JAMES EWELL BROWN** (1833-1864), American soldier, was born Feb. 6, 1833, in Patrick Co., Va. He graduated from West Point in 1854, but when the Civil War broke out in 1861 Stuart resigned his commission and accepted a cavalry command in the Confederate Army. He fought at Bull Run in July 1861 and in June 1862 led a spectacularly successful reconnaissance force completely around the Union army massed near the Chickahominy River. His cavalry took part in the Seven Days' Battle near Richmond and the Second Battle of Bull Run, and later in 1862 led the Confederate advance into Maryland. Stuart's troops knifed ahead into Pennsylvania in October to capture and burn the town of Chambersburg. Stuart commanded the Confederate cavalry in the Southern victories at Fredericksburg in December 1862 and at Chancellorsville in May 1863; in June 1863, shortly before the Battle of Gettysburg, he led his troops in a fierce though indecisive battle with Union cavalry at Brandy Station, Pa. Less than a year later, Stuart was mortally wounded in a skirmish at Yellow Tavern, Va., and died in Richmond the next day, May 12, 1864. Considered a genius with cavalry, Stuart was one of the most colorful and popular Confederate officers. W. E. A.

**STUART, MARY.** *See* MARY, QUEEN OF SCOTS.

**STUBBS, WILLIAM** (1825-1901), English historian and prelate, was born at Knaresborough, in Yorkshire, June 21, 1825. Educated at Ripon Grammar School and Christ Church, Oxford, he was ordained an Anglican priest in 1848 and in 1850 received the living of Navestock in Essex, where he commenced those researches which were to make him an outstanding scholar in medieval history. In 1862 he was made librarian at Lambeth Palace, and in the following year he became an editor of the noted Rolls Series, winning his first real success with his edition of the *Chronicles and Memorials of the Reign of Richard I* (2 vols. 1864-1865). As

Regius Professor of Modern History at Oxford, a post he held from 1866 to 1884, his main interest lay in medieval, and especially in constitutional, history. During this period he edited fifteen volumes of English medieval history for the Rolls Series, a magnificent and scholarly achievement. These included *Gesta Regis Henrici II* (1867), and *Memorials of Saint Dunstan* (1874). In 1878, in conjunction with A. W. Haddon, Professor Stubbs published *Councils and Ecclesiastical Documents covering the History of the Anglo-Saxon Church.* It is, however, for his *Constitutional History of England* (3 vols. 1874-1878), together with its companion volume *Select Charters and other Illustrations of English Constitutional History from the Earliest Times to the Reign of Edward I* (1870) that he is most widely known. Although later scholars have pointed out a number of defects in the Anglo-Saxon and Norman portions of this history, and, although his conclusions on parliamentary development are open to criticism, this work still stands as the foundation from which the study of English medieval constitutional history must begin. In 1879 William Stubbs became Canon of St. Paul's and in 1884 Bishop of Chester, an appointment which virtually marked the end of his historical researches, though not of his interest in history. In 1888 he was translated to the Bishopric of Oxford. He died at Cuddesden, Apr. 22, 1901. E. R. A.

**STUPA** [stu′pə], or tope, a mound or tower, commonly hemispherical, used as a Buddhist shrine. Hundreds of stupas or topes exist throughout India and Afghanistan, and many more have been recorded in Ceylon, Burma, Tibet, and China. The earliest stupas were probably erected shortly after the death of the Buddha Sakyamuni in 483 B.C., either to contain relics of the Buddha or to mark places associated with incidents in his life. Legend has it that in the middle of the third century B.C. the Indian emperor Asoka built 84,000 stupas, and it is certain that countless such structures were demolished in more recent times in the constant search for building materials.

The earliest surviving stupa seems to be the Great Stupa at Sanchi, which may have been begun in the Asoka period but which was certainly completed about 75 B.C. This monument displays some of the essential features of the later Buddhist stupas: a hemispherical mound of stone masonry and brick, it has a circumambulatory passage enclosed by a carved stone railing. However, there is no relic casket within the mound at Sanchi, and it also lacks the customary kiosk crowning the mound, to support a shaft decorated with disks that represent symbolic umbrellas.

The stupa form probably originates in the earthen burial mounds common in early periods to many regions of the world, although all surviving stupas are of masonry. They display marked regional and historical variations. For example, the profile of the mound is either hemispherical, bulbous, or conical; some stupas contain no relics, whereas others contain one or more reliquary caskets within the center of the mound, and in some cases the stone railing carved with scenes from the life of Buddha is missing and the drum of the mound has an applied pilaster decoration.

Noteworthy stupas include one at Peshawar, long vanished, which records state was 500 ft. high; the Great Stupa at Sanchi; one at Manikyala whose precise hemisphere is 127 ft. in diameter; and the Shwe-Dagon at Rangoon, 320 ft. in height, built in the eighteenth century. D. N. W.

**STURGEON,** a group of fish having a long fossil history and including the largest, present-day, fresh-water fish known. These large ganoid fish usually live in the sea, but they migrate into fresh water to spawn. Their snouts are long and somewhat pointed; the mouth is inferior and is so arranged that it can be protruded. There are four sensory barbels near the mouth to aid in locating food which is rooted out of the mud bottom. Five rows of bony scutes provide an armor for the long body. Mature adults migrate upstream in the spring to spawn. A large female may lay 3,000,000 eggs. The young stay in fresh water about a year before going to sea. There are about twenty species of

*The common sturgeon,* Acipenser sturio, *a ganoid fish found in the Atlantic region of Europe and North America*

sturgeon in the family Acipenseridae. *Acipenser sturio,* the common sturgeon of both sides of the Atlantic Ocean, was at one time common in the Hudson River but overfishing and water pollution have greatly reduced its numbers. At one time it was so common in the market that its red flesh was jokingly called "Albany beef." *A. huso* is the Russian sturgeon which is the source of the famous caviar. In the Volga River, specimens weighing over 2000 lb. are often captured. *A. transmontanus* is the white sturgeon of the Pacific coast; large specimens (300-600 lb.) enter rivers from Monterey, California, to Alaska. The shovel-nosed sturgeons, *Scaphirhynchus* and *Parascaphirhynchus,* much smaller (5 ft.) than the other sturgeons, are found in the Mississippi River system. The rock sturgeon, *A fulvescens,* is found in that system and in the Great Lakes. E. C. R.

**STURGEON BAY,** a city in northeastern Wisconsin, the county seat of Door Co., situated on Door Peninsula, 130 mi. north of Milwaukee, at the head of Sturgeon Bay, an inlet of Green Bay which is connected with Lake Michigan by a ship canal. It lies in the heart of the great cherry-growing districts of the country. The scenic beauties of the peninsula have also made it a popular resort. In addition to tourism and the industries connected with the cherry orchards, the commercial and industrial activities of the city include quarrying, shipbuilding, the handling of water freight, and fishing. On the outskirts of the city are a state fish hatchery and a branch of the University of Wisconsin's Agricultural Experiment Station. The first white man known to have passed through this area was Father Jacques Marquette in 1673. Sturgeon Bay was incorporated as a city in 1883. The city is governed by a mayor and council. Transportation is provided by the Ahnapee and Western Railway. Pop. 1950, 7,054.

**STURGEON FALLS,** a town in Nipissing District, Ontario, Canada, situated on the Sturgeon River, 3 mi. north of its entry into Lake Nipissing, and 24 mi. west of North Bay, on the Canadian Pacific Railway and Provincial Highway 17. A large paper mill is located in the town. In addition to the fishing industry, which is important, there are cooperage-stock and optical-abrasive factories. The surrounding region contains many tourist resorts. Pop. 1951, 4,962. D. F. P.

**STURGIS** [stɜ′rjɪs], a city and lake resort in southwestern Michigan, in St. Joseph Co., situated close to the Indiana border, 34 mi. south of Kalamazoo. The surrounding area is a fertile, diversified-farming district.

Founded in 1827, Sturgis was incorporated as a city in 1896. A manager and council administer the city, which lies in a district that was once famous Indian territory and a stronghold of the Potawatomi Indians. In the near vicinity is the junction of the Great Sauk Trail and the Nottawaseepe Trail. Transportation is afforded by the Pennsylvania and the New York Central railroads. Sturgis ranks among the first four cities in the state in the manufacture of furniture. Other manufactures include sales-record books, surgical elastic bandages, draperies, novelty paper products, hardware, brass specialties, and Venetian blinds. Pop. 1950, 7,786.

**STURGIS,** a city of western South Dakota, the county seat of Meade Co., situated in the Cheyenne River watershed area, 28 mi. northwest of Rapid City. Lying in a valley of the Black Hills, surrounded by an area noted for its cattle raising and farming, it is a market center for livestock, grains, and poultry. There are gold deposits in the region. Founded in 1878, when General Sheridan established Fort Meade on this site, Sturgis was incorporated as a city in 1888. The local government is of the mayor-councilmanic type. Sturgis was an important stop for the famous Deadwood stagecoach. Features in the vicinity are the Black Hills; the historic Indian shrine at Bear Butte; Rainbow Cliff, a brilliant geological formation; and the site of the famous Fort Meade Cavalry Post. The historic fort was turned over to the United States Veterans Administration in 1944, and in 1950 the Administration opened the Fort Meade Veterans Hospital there. Transportation is furnished by the Chicago and North Western Railroad. Lumbering is the principal local industry. Pop. 1950, 3,471.

**STURLUSON, SNORRI** [snɒ'rrɪ stɜ'rlɜsɒn] (1179-1241), Icelandic historian, poet, and chieftain, was born in Hvammur, Dalir, west Iceland. He was a member of an ambitious family of good stock, which in the first half of the thirteenth century made a bid for power in Iceland but lost out to more realistic opponents in alliance with King Haakon IV of Norway. Snorri was brought up in Oddi, a center of learning in southern Iceland, which was established by Saemund the Learned (1056-1133). In Oddi, Snorri studied law, poetry, and history, and thereafter he became a wealthy chieftain in Borg and Reykholt. He was killed with the king's connivance at his home in Reykholt, Sept. 22, 1241.

Snorri was the author of two outstanding works of Icelandic literature, the "younger" *Edda* and *Heimskringla.* He wrote poems in praise of at least three kings and two earls, but all that remains of these eulogies is the *Háttatal* section of his *Edda. Heimskringla* is composed of historical material that he collected on a trip to Norway and Gotland between 1218 and 1220. Besides these important works, he may have written *Egils saga,* the story of his famous poet-ancestor, Egill Skallagrímsson.

As a chieftain, Snorri was ambitious and shrewd, but he lacked courage and the cruelty that the times required. He loved splendor, was a lavish host, and shows in his writings that he was a dignified man of the world. As an artist he was fully equal to the best saga writers, and the modern historian Halvdan Koht has called him the foremost historian of the Middle Ages. *See also* EDDA, THE YOUNGER; HEIMSKRINGLA.

S. E.

**STURM, JACQUES CHARLES FRANÇOIS** [stü'rm] (1803-1855), French mathematician of German ancestry, was born at Geneva, Switzerland, Sept. 29, 1803. Sturm showed signs of genius at an early age. Before he was fourteen, he had completed the Geneva College course; he then studied at Geneva Academy and when only twenty-four received the grand prize in mathematics for his work on the compression of liquids. Sturm lived most of his life in Paris, where as a very young man he tutored the son of Madame de Staël. In 1829, then only twenty-six, he established his numerical equations theorem, famous throughout the mathematical world. In 1836 he was elected to the Académie des Sciences and in 1840 became a professor in the Ecole Polytechnique, where he shortly succeeded Siméon Poisson. Sturm's work, *Cours d'analyse de l'École polytechnique* (1857), was published posthumously. He died in Paris, Dec. 18, 1855.

**STUSS.** *See* CARD GAMES.

**STUTTERING,** sometimes called stammering, is a form of anxiety tension, manifested as a disturbance in the fluency of speech, motivated by an apprehensive anticipation of difficulty in initiating or maintaining an adequate flow of speech.

Pertinent surveys indicate that nearly 1 per cent of American school children stutter. According to Prof. Charles Van Riper, Dr. C. S. Bluemel, Dr. Emil Froeschels, and other authorities, stuttering generally begins in early childhood and nearly always consists of easy, simple repetitions and hesitations in its early stages. This general view has been confirmed and elaborated by studies reported from the State University of Iowa Speech Clinic, which indicate that the average age of onset of the difficulty is three years. The studies also indicate that children who develop stuttering do not differ as a group from nonstuttering children so far as intelligence, health, physical development, speech development, and general behavior are concerned. It is of particular importance that stuttering is usually originally diagnosed by laymen, usually the parents. What they diagnose as stuttering appears in the usual case to be indistinguishable from the ordinary repetitions and hesitations in the speech of normal young children, between the ages of two and five, who have been found to average 45 repetitions per 1,000 words.

As to treatment, there is general agreement that stuttering should be treated as a form of anxiety tension. The main objective is to reduce the anxiety or fear regarding stuttering, and by this means, and in direct ways also, to reduce the hesitancy and tension characteristic of the stutterer's speech. Mental hygiene, or personality re-education, also is indicated in many cases to counteract the maladjustive effects of stuttering. The treatment of young children is chiefly a matter of parent education designed to change the parents' evaluations of the child's speech, and the accompanying parental policies, so as to remove the sources of the child's anxiety tension, which may be harmfully increased by parental demonstration of concern or by actually instructing the child to stop and start over, to speak more slowly, or to stop and think.

W. J.

**STUTTGART** [shtu'tgart], an industrial and commercial city and capital of the state (*Land*) of Baden-Württemberg, in the southwestern part of the (West) German Federal Republic, about 40 mi. southeast of Karlsruhe. Between 1945 and 1951 it was the capital of the *Land* of Württemberg-Baden, one of the three component parts of the present state. The city lies among hills with its center a short distance west of the Neckar River and with the suburb of Bad Cannstatt on the river's east bank. First mentioned

in 1229, Stuttgart was after 1265 the favorite residence of the counts of Württemberg, became their capital in 1482, and developed rapidly as an industrial center in the nineteenth century. Between 1903 and 1929 thirteen suburbs, including Cannstatt, were incorporated into the city. Stuttgart was severely bombed in World War II, resulting in extensive damage to the city and its industries. Most of the city was built in the nineteenth century and presents a modern appearance, in so far as it survived World War II. Many of its noteworthy buildings were bomb-damaged, including Stifts Kirche, or Church of the Holy Cross, built between the thirteenth and fifteenth centuries, which was completely ruined; the sixteenth-century Old Palace, gutted and partly destroyed; and the eighteenth-century baroque New Palace, also gutted and partly destroyed. There are several fine squares and parks, including the 200-acre Palace Garden. Though generally damaged, buildings of note include the fifteenth-century St. Leonard's Church, the academy, the former Royal Library, the museum of art, and the polytechnic school. Stuttgart is the center of the economic life of Württemberg and of the southern German publishing trade. Its surrounding hills are dotted with vineyards and orchards. The city is an important rail junction, and its industries include the manufacture of electrical equipment, machinery, textiles, iron, motor cars, furniture, pianos, optical equipment, leather and metal goods, chemicals, beer, and foods. Pop. 1953, 566,000. C. C. H.

**STUTTGART** [stʌ′tgɑrt], a city in east central Arkansas, the county seat of Arkansas Co., situated in a prairie and agricultural area, 45 mi. southeast of Little Rock. Founded in 1879, it was incorporated as a city in 1887. The city government is of the mayor-councilmanic type. Transportation is furnished by the St. Louis Southwestern and the Chicago, Rock Island and Pacific railroads. Industries include the milling of rice, grown in the vicinity, and the manufacture of pumps and well drills. Pop. 1950, 7,276.

**STUYVESANT, PETER** [stai′vəsənt; stɔi′vəsɑnt] (1592-1672), Dutch colonial administrator, was born in West Friesland, the Netherlands, in 1592. In 1635, after several years of military service, he was employed by the Dutch West India Company, and in 1643 became governor of Curaçao and adjacent Dutch islands. As a result of a wound received in an attack in 1644 on the island of St. Martin, Stuyvesant lost his right leg and was forced to return to Holland to recuperate. The wooden leg he wore thereafter was decorated elaborately with silver bands and became known popularly as his "silver leg." In 1646 he sailed again to the New World as the Dutch West India Company's appointee to the director-generalship of New Netherland. Upon his arrival in New Amsterdam (later New York) on May 11, 1647, he inaugurated an administrative policy so bluntly assertive of the interests of his company that he alienated the sympathies of many of the local burghers. At a meeting with the New England Commissioners in Hartford in 1650, Stuyvesant settled a dispute of long standing by coming to a definite agreement on a boundary between Connecticut and New Netherland. In 1653 he established for the city of New Amsterdam a plan of municipal government closely patterned on that of the cities of Holland. During the next ten years, Stuyvesant's efforts failed to prevent the decline of Dutch influence on Long Island, but he fought back the Swedes, especially in the vicinity of what is now Newcastle, Del., and he kept the Indians under close restraint. In 1664 an English fleet appeared in the bay and demanded that the city capitulate to the Duke of York, who lay claim to all the land between the Connecticut River and Delaware Bay. Stuyvesant's plans for defense were opposed by the local burghers, and on Sept. 3, 1664, New Amsterdam was surrendered to the English. Stuyvesant went home to Holland in 1665 to defend himself against charges of misconduct. He retired to New York in 1667, and lived on his farm or *bouwerij,* from which New York City's Bowery takes its name, until his death in February 1672. He was buried in the vaults in Saint Mark's Church. M. K.

*PETER STUYVESANT*

**STYRIA** (*Ger.* **STEIERMARK**) [stɪ′riə, shtai′ərmɑrk], a province in central and southeastern Austria. A generally mountainous region with an area of 6,326 sq. mi., Styria is divided into three main geographical regions: the Upper Highlands, Central Styria, and Southern Styria. The Highlands, notable for its mountains and lakes, is a district of heavy industry, including iron and steel works in the valleys of the Mur and Mürz; an iron center near the Erzberg, a mountain of iron ore; and salt mines at Bad Aussee. Central Styria is less rugged than the Highlands, and Southern Styria is given over to fruit growing and vineyards. Styria produces the greater part of Austria's brown coal; timber is an important resource, and there is an abundance of hydroelectric power for manufacturing. The chief towns are Graz, Leoben, and Bruck. Graz is the provincial capital and Austria's second largest city.

The duchy of Styria was originally part of the larger duchy of Carinthia, and was a portion of the inheritance of Ottokar II of Bohemia, who was ejected from Lower Austria in 1278 by Rudolph I of Hapsburg, Holy Roman Emperor. Through marriage, both the duchy of Styria and the kingdom of Bohemia formally became Hapsburg crownlands. The subsequent history of Styria is inseparable from that of Austria. Following World War II the province was in the British occupation zone until the occupation of Austria was ended by the treaty signed May 15, 1955. Pop. 1951, 1,109,335. S. Van V.

**STYRON.** *See* Plastics (*Commercial Plastics*).

**STYX** [stɪ′ks], the "abhorrent" river, which in Greek mythology was considered the principal river of the underworld, around which it flowed seven times. Personified, Styx was described as a daughter of Oceanus and Tethys; she assisted Zeus against the Titans and was rewarded by

having the most solemn oaths sworn by her waters. Not even the gods dared to swear falsely by the river Styx. The Styx was also the name of a small stream in Arcadia, the waters of which were believed poisonous. G. E. D.

**SUBCONSCIOUS,** a psychiatric term to designate what James called our "other selves," or the state between the conscious and unconscious.

Freud regarded the subconscious as a level of psychical activity just below that of conscious awareness, in which material normally recallable and at the mind's "finger tips" is stored and can only be remembered or called to the conscious level by active and vigorous attempts to muster one's forces of mnemonics. In an attempt to avoid confusion over terminology, psychiatrists in recent times have favored the expression "fore-conscious," which they describe as an element of the mind which contains latently unconscious material, but which can be recalled by the individual himself. The concept of the subconscious implies a bit of instinctual behavior, habit training, and racial heritage.

This latter consideration led Karl Jung to modify Freud's psychology in the treatment and analysis of the concepts of consciousness and to postulate the personal unconscious and the collective or racial unconscious. The former consists of ontogenetic experiences, not retained in consciousness, but repressed as painful, unpleasant, or unsuitable. This material may gain conscious expression in dreams, slips of the tongue, or action. The collective or racial unconsciousness is the heritage of the entire racial past, the universal substratum common to all humanity. It is the historical background from which every mentality has evolved. Traces of experiences lived through ancestrally—phylogenetic—are engraved on the mind. J. A. Br.

**SUBJECTIVISM,** a term used broadly to emphasize the role played by self or mind in experience; or to stress the role of human in contrast to extra-human facts.

In metaphysics, subjectivism is the view that only subject, mind, or human experience is real or is the source of real things. Extreme subjectivism, illustrated in solipsism, holds that the individual self is the only reality.

In epistemology, modern subjectivists have advanced the following theories of knowledge: (1) that the criteria for knowing the external world with certainty, e.g., "clear and distinct ideas" (Descartes), are found within the mind itself; (2) that the only objects known, ideas, are themselves within the mind so that the world as known is the subject's presentation (a view held with reservations or inconsistent factors by Locke, Berkeley, and Hume); (3) that the subject is a windowless whole of experience, a "monad," which reflects, or is a representation of, reality (Leibniz); (4) that the subject provides the forms of perception (time and space) and the categories of understanding (e.g., cause, plurality) which are imposed upon our sense experience of the external world (Kant); (5) that an individual's belief constitutes knowledge if it "works satisfactorily in the widest sense of the word" in human experience (pragmatism).

Regarding values other than truth values—moral, æsthetic, religious—subjectivism is the doctrine that values are created by, limited to, or interpreted by the individual wholly in terms of factors in his own experience—imagination, will, or feeling—so as to provide him with a feeling of happiness, pleasure, or satisfaction. H. Bn.

**SUBLIMATION.** *See* Changes in Matter; Psychoanalysis (*Mental Mechanisms*).

**SUBMARINE,** a boat or like device, other than a diving suit or helmet, which enables men to descend under water, remain there an appreciable time, and return to the surface. Typically, it is a watertight, self-propelled craft, strengthened to resist depth pressure, fishlike in shape, achieving submergence primarily by admitting water to ballast tanks and so neutralizing its own buoyancy. A distinction has been drawn between submersibles, which are surface craft capable of submerging, and submarines, vessels operating exclusively or mainly under water. In this sense, the submarine has only within the present century become a practical reality.

### THE BASIC PROBLEMS

How far back the urge to live, move, work, and fight under water goes we cannot tell, but there is evidence that it was a matter of interest over 2,000 years ago. This is true not only of the inclination to dive and swim, with or without artificial diving dress and breathing equipment, but of the desire to descend in boats or boatlike vehicles—in short, by submarine.

Before any real progress could be made toward inventing the submarine as we know it today, there were major theoretical and mechanical problems to be solved. How could a boat or chamber be made to sink below the surface and yet return to it? What would be the effect of the pressure at great depths? How could a vessel be propelled from place to place under water or be kept on an even keel? How could the submarine navigator see where he was going, or steer? How were the boat's occupants to breathe? Behind these problems lay the basic properties of water itself, of floating structures, and of human anatomy, which established the framework within which submarine science must develop. Though they seem fairly obvious today, many of them were perceived only gradually, as the results of experiment, the experimenter not even being aware that such problems existed until they were encountered, perhaps with fatal consequences. Sometimes, the problem was recognized and solved in theory many years before it was overcome in practice. The mathematicians and philosophers of antiquity established a number of the fundamental principles of the submarine 2,000 years before human need compelled or technology permitted their application.

**Buoyancy.** Sea water weighs 64 lb. per cu. ft. Any object—including a watertight vessel and the air it contains—which weighs less will displace only its own weight of water and remain afloat; it has positive buoyancy. Any object which weighs more than 64 lb. per cu. ft. will displace its volume of water and sink; it has negative buoyancy. If a hole is poked in a ship's steel hull so that inrushing water replaces its air content, the vessel will become heavier than water and go down. Its positive buoyancy becomes negative. This, in oversimplified form, is how a submarine submerges.

The submarine, unlike the punctured hull which goes to the bottom and stays, must be able to stop part way down and to resurface. To do this, it must take advantage of another property of water, its pressure. Since a cubic foot of water weighs 64 lb., a box measuring 12 x 12 x 12 in. will have 64 lb. of pressure on its top at a depth of one foot. However, the pressure on its bottom, which is 2 ft. down, will be doubled or 128 lb. The difference between the pressure on the top and that on the bottom is 64 lb. If the box has positive buoyancy, this difference will push it to the surface; if it has negative buoyancy, it will not prevent its sinking. But, if just enough water can be admitted to the box to give it and its contents a weight of 64 lb., it will have neutral buoyancy

and will remain suspended at any depth, without rising or sinking.

A submarine is subject to the same rules as the box. It submerges by the controlled admission of water to its tanks; it remains at a given depth by achieving neutral buoyancy; it resurfaces by expelling enough water to regain positive buoyancy.

Submarine hulls must be of great strength. With pressure increasing at the rate of 64 lb. per sq. ft. for every foot of descent, it does not take long for water to build up a force capable of crushing most man-made structures, not to mention human beings themselves. Men descending into deep water in diving suits must be given compressed air to breathe or the difference between internal and external pressure will crush them to death. In a submarine they do not need this precaution, for the boat's main or "pressure" hull must be strong enough to resist the pressure at any depth to which it may descend.

**Steering and Stability.** Control and direction of a submerged vessel involve different problems and, therefore, different methods from surface craft. The latter need only be steered to right or left; the submarine must also be steered up and down. Hence, it must have horizontal rudders or "diving planes," as well as the conventional vertical rudder. Most important, the submarine must be provided with a means of keeping it on an even keel at any depth, for diving planes alone cannot do this. A submerged vessel responds much more freely to any shift in its longitudinal center of gravity than one floating on the surface. It was not realized for many years that the chief hazard in this respect was the ballast tanks by means of which a submarine was enabled to submerge.

Anyone who has tried to carry water in a wide, shallow pan knows how abruptly it will rush to one side at a slight deviation from the horizontal. The same phenomenon, on a large scale, occurred in the tanks of many early submarines, which were generally filled only as far as was necessary to submerge the boat. This usually left an extensive free surface in the tanks, which permitted the water to slosh and impaired the vessel's longitudinal stability. At any small shift in its center of gravity, the water in these tanks would rush to one end, often throwing the whole boat into such an extreme nose-dive or tail-dive that no amount of engine and rudder power restored her to the horizontal.

**Vision.** Though it is a transparent substance, sea water is usually not easy to see through. Daylight in useful quantity penetrates only a few feet below the surface, as a rule, and even powerful artificial lights are helpful only at close range. Glass observation ports, therefore, have never been of much use to a submarine under water. John Holland, an American submarine inventor, reported that they were of no real assistance in guiding his early boats; a surface vessel floating close overhead was nothing but "a dark shadow." (Probably the most fantastic feature of Jules Verne's *20,000 Leagues Under the Sea,* even today when much of its fiction has become fact, is the provision of windows through which his submarine voyagers might gaze out upon wide sea-bottom landscapes.)

The only way by which early submariners could see where they were going was to surface the submarine so that they could peer through its portholes, as in the case of Holland's vessels, or to come near enough to the surface to use a periscope which was raised above the surface of the water. At present, electronic instruments tell a navigator many fathoms below the surface all he must know about the surrounding water and its occupants.

**Ventilation.** Since men must have air to breathe, there was a deep-rooted fear of suffocation if one went under water in any sort of sealed vessel. Some actual and proposed submarines, even at the end of the nineteenth century, were provided with flexible air hoses supported by floats on the surface or with hollow masts. In point of fact, the hazard may have been slightly overrated. Men normally inhale air containing 20 to 21 per cent oxygen and exhale air containing about 16 per cent, the balance of the oxygen being replaced by carbon dioxide. At this rate, the oxygen supply in even a small sealed chamber will last quite a while. Actually, it is the build-up of carbon dioxide in the air, rather than oxygen exhaustion, which is dangerous. Since World War II the atmosphere of submarines has been kept fresh with a $CO_2$-absorbent, lithium hydroxide.

More than 150 years ago, compressed air was first used to allow men to remain under water at least until the tanks or bottles were exhausted. Compressed air recently has become a necessity not only for breathing, but also for blowing water from the ballast tanks for surfacing, and an air compressor is now standard equipment on submarines. The latest submarines also carry oxygen tanks to replenish the air for breathing.

## EARLY SUBMERSIBLES

**Diving Bells and Diving Chambers.** The simplest way to go under water dryshod is to be lowered in some sort of container which like an anchor sinks because it weighs more than the water it displaces and which returns to the surface solely because it is hauled up. The container may be completely watertight; it may be open at the bottom so that a supply of air remains trapped within it, the water rising into it only to the extent that the pressure at any given depth compresses the trapped air. In the first instance, it is a prototype of the bathysphere; in the second,

of the diving bell. Though the evidence is not explicit, it appears that both these types of submergence chamber were known and used in ancient times.

*Diving Bells.* Aristotle speaks of the use of diving bells in the 4th century B.C., and Pliny alludes more vaguely to diving equipment. Early Greek sponge divers are said to have utilized the diving bell principle by submerging large inverted jars near their working ground and ducking their head into them for a periodic gulp of air. A pre-Christian, watertight diving chamber is the "glass barrel" in which, according to legend, Alexander the Great submerged to satisfy his curiosity about undersea life.

During the Renaissance, experimentation with diving bells continued. Roger Bacon and Leonardo da Vinci are both credited with underwater devices. A "notable diving bell" was tried at Toledo, Spain, in 1538. About 1640, a submarine "packet" invented by John Barrié was reportedly used in salvage work at Dieppe, France.

At the start of the eighteenth century, Dr. Edmund Halley of comet fame perfected a device which may be called the first fully successful diving bell. It was built of wood and enabled five occupants to remain 60 ft. under water "above an hour and a half" by virtue of an air-supply system consisting of two barrels, one of which was filled with air at the surface and lowered as the other was pulled up. Increasing pressure on the descending barrel pumped its air content into the bell through an oiled leather hose, while Halley released stale air from a valve at the top.

Except for the absence of compressed air, Halley's invention set the pattern for the modern diving bell. With compressed air added, water could be prevented from rising in the bell as hydrostatic pressure increased. The caisson, which is fundamental to all present-day underwater construction and excavation, is simply a specialized, outsize diving bell in which air pressure is employed to keep out water and provide a dry working area. Another modern version is the nautilus (a name of frequent occurrence in submarine literature). This is a self-controlled, nonsuspended bell, partaking of the character of a submarine boat. It is sunk by admitting water to its outer chambers, but its buoyancy may be so regulated that, in still water, workmen inside can move it in any direction by pushing.

A bridge between the submarine and the diving bell is the series of at least 14 boats built on the Mississippi system between 1840 and 1870 and named *Submarine No. 1, Submarine No. 2,* etc. They were not in themselves submersibles but paddle-wheel steamers incorporating diving bells. The invention of James B. Eads, they were used in the salvage and removal of wrecks and other obstacles to navigation. One, *Submarine No. 7,* was later converted to the gunboat *Benton* during the Civil War.

*Diving Chambers.* While the diving bell was ideally suited to underwater salvage, construction, and demolition work, the watertight chamber was much better adapted to scientific exploration of great ocean depths. Alexander's glass barrel, however, would scarcely have served William Beebe and Otis Barton on their 35 deep dives off Bermuda in the early 1930's. They employed the bathysphere, a hollow steel ball about 5 ft. in diameter, designed to endure enormous pressures without collapsing and suspended by cable from a surface vessel. Electrical connections powered its oxygen-circulating system and 2,600-candlepower searchlight by whose beam, through peepholes of three-inch fused quartz, Beebe and Barton observed the nearby ocean life. In their record dive the two men were able to reach a depth of 3,028 ft.

Far greater depths have lately been attained by European scientists using a bathyscape, which resembled the bathysphere in that its passengers rode in a spherical steel chamber, much more heavily constructed. It was not, however, suspended from a surface vessel but attached, like the gondola of a blimp, to a free-floating tank filled with a liquid much lighter than water and, hence, buoyant. Heavy metal ballast attached by electromagnets sank this "submarine balloon" to the desired depth and, when released, permitted its return to the surface. The bathyscape was designed by Professor Auguste Piccard, who on Sept. 30, 1953, descended into the Mediterranean with his son to a depth of 10,330 ft. The following February, Georges Houot, an officer of the French Navy, reached a depth of 13,284 ft. in a similar device in the Atlantic.

A specialized diving bell with certain characteristics of the submarine is the McCann rescue chamber, first used with great success to save the survivors of the sunken U.S. submarine *Squalus* in May 1939. Ten ft. high and 8 ft. in diameter at its widest, it is divided by a hatch into upper and lower compartments. Ballast tanks and compressed-air connections permit buoyant control while it is being lowered and raised by the salvage vessel. The rubber-gasketed skirt of the lower compartment fits snugly on the standard escape-hatches built into all modern American submarines. *See also* SUBMARINE RESCUE CHAMBER.

**Early Submarine Boats.** As with most other technical innovations, it is impossible to say of the submarine that a particular person invented it at a particular date. Assorted craft, having some of the submarine's characteristics, were devised over more than three centuries. In fact, the revolutionary advances being made today suggest that the submarine may not have been fully "invented" yet.

Early in the sixteenth century, Oalus Magnus, Bishop of Uppsala, reported having seen submersible leather boats which had been captured from pirates who used them to sink passing merchantmen. Whether he was looking at the first real submarine or aboriginal kayaks is a matter of some doubt. In 1573, William Bourne planned a submerging boat which, if built, would have embodied ingenious solutions to the problems of buoyancy and ventilation. It was to have a "double hull"—a vented leather skin enclosing an

inner shell of wood—and to receive or expel water ballast as screw jacks distended or contracted its sides. A hollow mast reaching above water was to supply air.

The earliest circumstantial reports of a vessel navigating below the surface concern a wooden rowboat decked over with watertight leather. It was built by Cornelis Drebbel and used on the Thames River between 1620 and 1624. Propelled by oars working through leather seals, it made trips "several hours" long at a depth of 15 ft. King James I is said to have ridden in it. Although there is ample proof of its existence and the great public interest it evoked, there are no surviving technical data on Drebbel's invention. We do not know how he submerged, how he steered, or how the vessel got air. Contemporary accounts speak cryptically of his carrying a vessel of "chymical liquor" which he could uncork to purify the air when it became "troubled."

Another seventeenth-century submarine, the "Rotterdam Boat" of the French inventor De Son, is significant because she was designed for military use, unlike Drebbel's. Built of wood, the Rotterdam boat was 72 ft. long and was propelled by a paddlewheel midship. Despite reportedly successful trials, De Son could interest neither the Dutch nor the French in using his invention against the British.

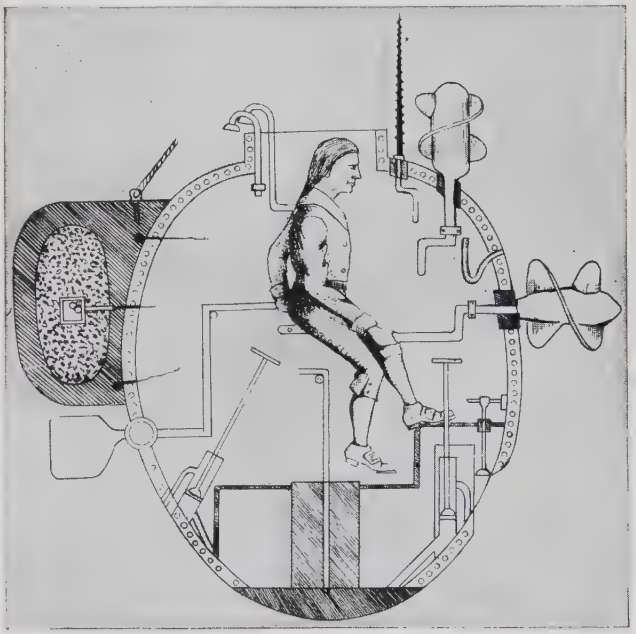
Striking gains in submarine technology were made in the eighteenth century and, by its end, several basic problems had been solved or their solutions were clearly foreshadowed. About 1730 an Englishman named Symons developed a French idea formulated 50 years earlier. He installed in a decked rowboat a crude prototype of the ballast tanks which modern submarines fill to submerge and blow to surface. Symons' tanks were leather bags with necks opening through apertures in the bottom of the boat. To raise his vessel, he squeezed the water out of the bags by leverage and tied their necks.

*The Turtle.* Two months after the Declaration of Independence was signed in 1776, the first American submarine made the first recorded underwater attack on an enemy vessel. The *Turtle,* designed and built by David Bushnell of Connecticut, attacked the British frigate *Eagle* anchored in New York Bay. In form, the *Turtle* was unique. Built of oak and shaped like a coconut, she stood on end in the water instead of lying flat. A brass conning tower—the submarine's equivalent of a pilot house or navigating bridge—was located on the upper side of the vessel. It was of the most rudimentary sort, being simply a raised circular hatchway with several small glass peepholes set into its sides. The one-man crew sat with his head projecting into the conning tower so that he could look out through the portholes when the *Turtle* was awash. At the lower end of the coconut was a quantity of lead ballast, part of which was external and detachable, and tanks which could be flooded by a pedal valve and emptied by a force pump. Buoyancy could thus be controlled so that the *Turtle* neither rose nor sank in the water. Horizontal movement could be achieved by cranking one small propeller on the screw principle; vertical movement, by turning another. There was no underwater air supply. Since air was admitted only when the vessel was awash through valves which closed automatically if water overflowed them, the *Turtle* could stay under only about half an hour.

Armament consisted of a piggyback time bomb made fast to an auger which the operator was to screw into the bottom of the enemy ship. When the time came for the *Turtle* to distinguish herself in combat, however, the auger could not pierce the *Eagle's* copper sheathing, and the *Turtle* had to cast her ticking torpedo adrift. A second contact was never made, and the *Turtle* was finally sunk by the British, while out of action and unmanned.

The *Turtle* set valuable patterns for future submarine development. Notable among them are the use of ballast tanks, conning tower, and screw propeller, and the proof that underwater attack could take an enemy by surprise. Writing 120 years later, John P. Holland called the *Turtle* "the most perfect thing of its kind constructed before 1880."

*The Nautilus.* In Paris at the turn of the century Robert Fulton had plans for a submersible warship—plans on which he set more value, according to some of his statements, than on his work on the steamboat. Interest in Fulton's plans was shown by Napoleon after he seized power in France in 1800. He advanced some funds, but Fulton worked mostly without encouragement. His vessel was the first submarine to be named *Nautilus.* In some respects, she seems to have owed not a little to Bushnell. Like the *Turtle,* she was screw-propelled under water, was submerged by admitting the sea to ballast tanks, had a conning tower, and was fitted with a sharp detachable spike attached to a torpedo (Fulton's word, from the electric ray, *torpedo electricus*) to be planted in the hull of a target ship.



SUBMARINE LIBRARY, GROTON, CONN.

*INTERIOR PROFILE OF DAVID BUSHNELL'S SUBMARINE, THE* TURTLE

Unlike the *Turtle,* the 21-ft. hull of the *Nautilus* approximated for the first time the fish-shape of modern submarines. The propeller, though turned by hand, pushed rather than pulled the vessel through the water. In still other ways the *Nautilus* was more like a submarine of the twentieth century than any of her predecessors: she was moved up and down by horizontal rudders, similar in principle and operation to the elevators of an airplane; the initial air supply was replenished from a small tank of compressed air; she was provided with a dual-propulsion system—the screw for submerged operation, a folding mast and sail for running on the surface.

When Napoleon lost interest, Fulton abandoned his boat and took his plans for both the submarine and the torpedo to England. There he demonstrated the latter by destroying the target brig *Dorothea.* The British did not want a sub-

marine, and he returned home to perfect his steamboat. Although he subsequently built the first steam warship, it is not clear that he ever reverted to the submarine project. At his death in 1815 he was building an 80-ft. boat to be propelled by a "silent engine" and named the *Mute*. This may have been a surface craft; however, a government report written half a century later says it was to run on the surface "habitually," but that "on approaching the enemy, it was to dive quickly under the water."

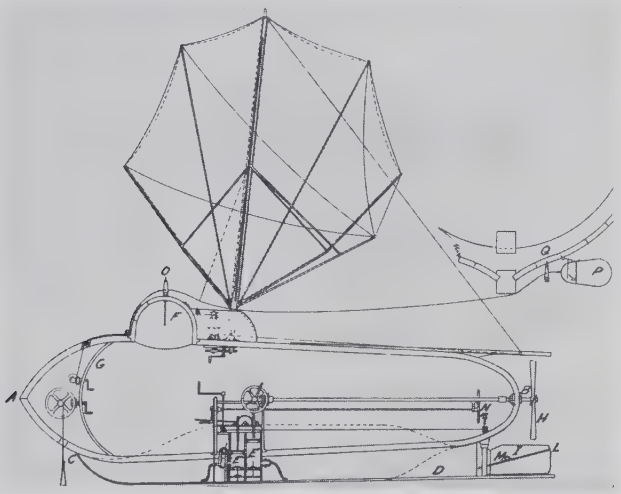


*Diagram of Fulton's* Nautilus *showing: AB, the ellipsoidal body; CD, metal keel; EE, pumps; F, metal conning tower; G, cross bulkhead; H, propeller; I and L, vertical and horizontal rudders, with fulcrum, M, and gears, N; O, horn; P, torpedo; Q, bottom of the vessel.*

*Last of the Muscle-Boats.* For more than half a century after Fulton abandoned the *Nautilus,* no significant contributions were made to submarine science. The one major problem Bushnell and Fulton had not solved (a strange omission in Fulton's case) was that of adequate power to turn the screw propeller, established as standard equipment after the *Nautilus* appeared. Their numerous and often talented successors did not begin to solve the problem until the last quarter of the nineteenth century. The 52-ft. *Diable Marin* which Wilhelm Bauer built to sell to Russia during the Crimean War, though formidable in many respects, could move only as fast as her crew's legs would work the treadmill which turned her propeller shaft. The 40-ft. submarine cigar with which in 1851 Lodner Phillips explored parts of Lake Michigan was also successful in many ways—apart from her limitation to one manpower and her apparent inability to withstand the pressure to which he exposed her on his last fatal dive in Lake Erie.

The American Civil War produced no important advance in submarine science. Its one true submersible, the Confederate vessel *Hunley,* was propelled by eight men laboring at a crankshaft. She was running on the surface when she drove her spar-torpedo against the U.S.S. *Housatonic,* sinking it and herself. This was the first sinking of a ship by a submarine. Even as late as 1872, the U.S. Navy seriously considered a clumsy, manpowered, iron blimp named *The Intelligent Whale* which was to anchor under water and send out a diver to torpedo things. At this date, ironically, Jules Verne had already published *20,000 Leagues Under the Sea;* its *Nautilus* not only embodied every improvement then envisioned by submarine science but possessed a mysterious, virtually unlimited source of power. By the light of contemporary technical progress, as exemplified by *The Intelligent Whale,* Verne was a visionary indeed!

**The First Powered Submarines.** *Compressed-Air Engines.* An attempt to improve submarine propulsion was made in great secrecy by the French Navy in 1863. *Le Plongeur,* a 146-ft. boat designed by Charles Brun, had an 80-hp. compressed-air engine. For some reason, she seems to have been little faster than craft which depended on human muscle power and was almost unmanageable under water. She is credited, however, with an innovation which is standard in twentieth-century practice—the use of compressed air to expel the water from the ballast tanks when surfacing.

*Steam Engines.* Two other sources of marine power were available to submarine designers: steam and electricity. Steam had obvious drawbacks for underwater craft, but in 1879 an English clergyman named Garrett set out to overcome them. When his *Resurgam* (meaning, "I shall rise again") was ready to dive, its smokestack was retracted, its fires sealed off, and the steam from its boilers used until exhausted. Two years later, the Swedish inventor Thorsten Nordenfeldt, now in partnership with Garrett, adopted this same system and so improved on it that the submarine *Nordenfeldt I* could run 14 mi. on her bottled steam. Nordenfeldt and Garrett also revived Bushnell's plan of submerging by the action of vertical propellers instead of diving planes. They were probably the first to adopt the self-propelled torpedo as the submarine's chief armament.

*Nordenfeldt I* was sold in 1886 to the Greek Navy; two others were purchased by Turkey. All had serious initial trouble keeping a horizontal position under water. Nordenfelt submarines later became popular and were the first type adopted by the German Navy.

*Electric Engines.* The French were the first to experiment intensively with an all-electric drive for submarines. This type of power had previously been installed in an English *Nautilus* which failed in 1884 to justify a new system of submergence devised by her builders, Campbell and Ash, and in a Spanish submarine brought out by Don Isaac Peral in 1887. The first French electric boat was the 59-ft. *Gymnote,* completed in 1888 according to plans originally drafted by Dupuy de Lôme and finished after his death by Gustave Zédé. She was equipped with a 55-hp. motor, a telescopic conning tower, and diving planes (horizontal rudders on the order of those used by Fulton 90 years before). The *Gymnote* was the first submarine commissioned in the French Navy. Although neither she nor her larger successor the *Gustave Zédé* were wholly successful, the French built other electric boats before 1901.

The trouble with these power sources—steam, compressed air, and electricity—was that they were exhausted so soon. This either imposed an absolute limit on cruising range, since an electric or air boat had to return to base frequently to charge her batteries or bottles, or compelled the boat, if a steamer, to surface, fire up, and so advertise her presence.

## THE MODERN SUBMARINE

**Holland and the First U.S. Naval Submarine.** Most submarines late in the nineteenth century suffered from a movable center of gravity. Motion under water was consequently erratic and often amounted to loss of control. The man who was to lead in solving these two problems was already at work in the United States. He was a New Jersey schoolteacher named John P. Holland who had been planning submarines since 1859, when he was a youth of seventeen in Ireland. Convinced that deficient power had caused

all previous submarine failures, he was considering a gunpowder engine when other designers were relying on human strength. Newly come to America in 1872, he resumed his experiments, settling himself several problems besides that of propulsion. He was interested in attaining proper ballast, buoyancy, and trim; in methods of storing energy and air; in obtaining clear vision; in strengthening the hull, and perfecting a self-propelled torpedo installation.

His first proposed boat, designed in 1875 but apparently never built, was to have been a 10-ft. capsule, 2 ft. in diameter. The operator reclined in it, breathing air from the fore and aft chambers through a respirator and turning the propeller by foot pedals. As in the case of Bushnell's craft, provision was made for an external torpedo which was to be attached to enemy hulls. *Holland No. 2* followed. In it the inventor conducted many trials on the Passaic River in New Jersey. It was a one-man craft with a double hull, between which were ballast tanks, and a four-hp. petroleum engine, one of the earliest and least successful internal-combustion power plants.

The first really competent Holland model was a 30-ft. three-man craft built in 1881 and nicknamed the *Fenian Ram* because it was financed by the Irish expatriate Fenian Society. Propelled by the 17-hp. double-acting oil engine just perfected by Brayton, she made 7 mph on the surface. She had vertical and horizontal rudders, could dive "with dexterous swiftness," and was armed with an "air gun or bow tube" from which dynamite could be discharged under water. Holland experimented intensively with her for two years, learning, among other things, that "guiding a boat by direct vision while submerged was impracticable."

Holland's designs won him a government contract in a public competition in 1893. The submarine he built on the contract was the triple-screw *Plunger*. It was to have been driven by steam on the surface and by electricity below, but was unsatisfactory. Holland therefore devoted time to further development work. In 1898, he launched the epoch-making *Holland*. After two years of experiments, modifications, demonstrations, and government tests, the *Holland* emerged as the first practical and reliable submarine in history. She was 53 ft. long with a maximum diameter of 10 ft. 3 in. and a displacement of 74 tons on the surface. She had two horizontal rudders and a three-bladed screw. A gasoline engine of 50 hp. enabled the *Holland* to do seven knots on the surface; electric motors drove her along at six knots when she was submerged. Thus, the dual-propulsion system characteristic of submarines built in the next 50 years was first successfully achieved by Holland.

The vessel had no periscope (Holland had included one in the plans for the unfinished *Plunger*), glass portholes being built into the low conning tower. Steering the vessel toward a target and aiming its forward torpedo tube was accomplished by "porpoising"—rising quickly to the surface for a sight and promptly submerging again. The boat was purchased by the U.S. government on April 11, 1900. Named the *U.S.S. Holland,* it was the first naval submarine.

The *Holland* and all typical Holland submarines had a single hull. Ballast tanks were placed low within the main pressure hull, instead of between it and an outer hull as in double-hull vessels, such as *Holland No. 2* and the French *Narval,* commissioned in the same year as the *Holland.* Holland made it a rule that the main ballast tanks must be full when the boat was in diving trim, thus stabilizing the center of gravity and eliminating the sloshing and resultant underwater see-sawing which had plagued early boats. The adjustments necessary to establish neutral buoyancy and trim he carried out by means of smaller tanks.

**Lake and His Submarines.** Holland's chief rival in perfecting the submarine was another American, Simon Lake. A boyhood reader of Jules Verne, Lake determined to make a submarine like Captain Nemo's *Nautilus,* as much at home on the bottom as anywhere else. Unlike most of his contemporaries, he did not think of the submarine as purely an instrument of war.

His first plan, which lost out to Holland's in the 1893 competition, was for a double-hulled, twin-screw craft with vertical propellers for submerging, a folding periscope, and retractable wheels for running on the bottom. An air lock allowed divers to leave and return to the boat. It was a compartment with one watertight door closing it off from the rest of the boat and another opening to the sea which was to be kept out by increased air pressure within the compartment. The plan also embodied a solution to the problem of longitudinal instability, which Holland was working on along other lines at the same time. Lake's idea was to keep the submarine on an even keel at all times, even when descending and ascending, by means of a multiple system of horizontal vanes and rudders placed at bow and stern. This enabled both ends of the vessel to be raised or depressed together. Larger side fins, somewhat like stubby airplane wings, maintained level forward motion.

Lake actually constructed his first boat on much simpler lines than these. The *Argonaut, Jr.* of 1894 was a triangular wooden box 14 ft. long by 5 ft. deep, with three solid wooden wheels on which she could be cranked along the bottom by hand. As a result of her success, Lake built in 1897 the 36-ft. *Argonaut* driven by a 30-hp. gasoline engine. Engine and occupants were supplied with air through a floating tube, which later was replaced by tall hollow masts. The typical Lake wheels and diving port were present.

*THE FIRST SUBMARINE OF THE U.S. NAVY, THE U.S.S. HOLLAND*

SUBMARINE LIBRARY, GROTON, CONN.

In 1898 Lake rebuilt the Argonaut, adding a schoonerish superstructure to her low cigar-shaped hull. This addition, vented to flood when submerged, added greatly to her seaworthiness on the surface. It also set a pattern for submarines of our century. Before the *Argonaut* appeared, boats usually had a completely watertight hull, entered through a hatch at the top of the watertight conning tower which rose from the pressure hull. After 1900, most submarines followed Lake's design and carried a "free-flooding superstructure." This is an enlarged bridge over the conning tower and decks. It runs most of the length of the hull and tapers at the bow to a conventional surface-craft cutwater. Such a superstructure is usable only in surface cruising. It is not watertight, but pierced with enough openings so that the sea fills it as the boat submerges and drains off automatically as it rises.

In summary, Lake's contributions to submarine technology included his system of submergence without slanting the keel, his air lock for divers, the free-flooding superstructure, and a primitive sort of snorkel tube.

**Nonmilitary Submarines.** Men have had many motives, latent and professed, for building submarines. Most wanted to produce a war machine; some—like Fulton and, in one of his moods, Holland—hoped to make war so terrible that it must be abolished. Of this latter persuasion was Professor Josiah Tuck, who opposed Holland, Lake, and Nordenfeldt in the 1893 contest. His *Peacemaker* was a 30-ft. steel submarine propelled by a "fireless steam engine" in which heat was generated by caustic soda. At first she carried a diver in an open cockpit on top. His job was to place electrical buoy-torpedoes under enemy ships.

Among the nonmilitary purposes suggested for submarines have been transportation, exploration, and salvage work. Submarines for the peacetime carriage of passengers and cargo have had many advocates; for years, it was argued that travel would be far swifter and more comfortable under water than on the surface. As early as 1650, De Son said his "Rotterdam Boat" would travel as fast as a bird and make a round trip between Rotterdam and London in a day. In 1889, the Russian submarine enthusiast Apostoloff was advocating a submarine craft threaded like a screw, to spin its way across the Atlantic in a little over 24 hours. Goubet, inventor of two practical French electric submarines, proposed in 1902 an undersea passenger liner to divest ocean-travel of all terrors.

Except for Drebbel's underwater excursion boat, such submarines have remained proposals only. The submarine, as it gradually evolved, continued to be slower under water than awash, more uncomfortable than the most uncomfortable surface ship, and far too small to carry a payload of freight. Only the exigencies of war have occasionally forced it to be a carrier. In 1916 the *Deutschland* maintained a brief and tenuous merchant service to and from America through the British blockade before being converted to a fighting craft. In World War II, naval submarines of several combatants carried high-priority passengers and cargo to points they had to reach by stealth, and it is known that since 1945 our navy has experimented with merchant-type conversions. Several large submarines have been made into troop transports, cargo carriers, and oilers.

Some early inventors, including Phillips and Lake, numbered exploration among the possible uses of the boats they built. In 1931 Sir Hubert Wilkins used the former USS O-12, converted and renamed *Nautilus,* for his north polar expedition, penetrating within 450 mi. of the Pole in her. The outstanding nonmilitary function of the submarine to date has been in performing salvage and similar work under water. For a time in the last century, it appeared that this might rival the submarine's utility as a weapon. It is not entirely clear whether Barrié's seventeenth-century "packet" was a submarine or a diving bell. Dr. Payerne built his *bateau cloche* in 1846; it was a 35-ft. screw-propelled semi-projectile which divers could leave and enter under water. It is said to have worked successfully on the Cherbourg breakwater.

In 1851 Phillips reported that he had sawed 14-in.-square timbers under water from inside his Lake Michigan submarine. Simon Lake demonstrated the feasibility of salvaging material from sunken wrecks. He accurately perceived that an effective salvage submarine must be able to carry divers to their working area, let them out on the bottom, and take them back when the job was done.

At the turn of the twentieth century, several European inventors devised submarine working boats. The Italians, Piatti del Pozzo and Cavaliere Pino, produced spherical or ovoid craft. Although they were equipped with screw propellers, they were designed to work suspended from surface vessels, the ovoid vessel at depths exceeding 300 ft. Degli Abbati built *L'Audace,* a 28-ft. flattened projectile carrying four men. It was lighted and driven by electricity. The Abbe Raoul of Tunis Cathedral is also credited with a successful 16-ft. lemon-shaped boat.

These "peaceful submarines" had a common defect: experience showed that their functions could be more efficiently and less hazardously performed by divers, diving chambers, or surface craft. Hence, they have had few successors. The submarine has become ever more exclusively a weapon—more terrible each year.

**Submarine Developments in the Twentieth Century.** By the start of this century, only a few standard items of equipment had yet to be added to or to become universal on the submarine. The periscope, known to submarine science since at 1854 at least, had been incorporated in both Holland's and Lake's 1893 plans. Perfected in Europe, it was installed on a U.S. submarine of the predominant Holland type in 1902. Development of the gyrocompass gave the submarine its bearings under water; magnetic com-

passes had been almost useless when crowded by so much steel and electricity.

Fully practical propulsion came when the diesel engine replaced the tricky and dangerous gasoline power plant for surface drive. Adopted by the Germans in 1906 and by the British soon after, it came to be universally used either directly or in diesel-electric installations. Steam was employed, however, in the large, fast British K Class of World War I. More recently, atomic and other advanced power sources have been developed for submarines.

The single-screw propulsion of the Holland prototype was replaced by the twin screw, and single-hull construction by double-hull with main ballast tanks on the sides outside the pressure hull. Underwater communication was greatly advanced by the adoption of the oscillator. This device is based on the theory which enabled development of the telephone. It permits detection of nearby vessels and the receipt of messages under water, where radio is useless.

Since 1900 the submarine has evolved exclusively as an instrument of war. Its basic weapon has been the self-propelled torpedo, generally driven by compressed air or, more recently, by electricity which leaves no telltale wake. Deck guns and machine and anti-aircraft guns have also been carried; the trend at present is toward removal of these surface-type weapons.

There were no revolutionary changes in the structure, propulsion, and equipment of submarines from the start of World War I to the closing months of World War II. Among major problems to be solved were increasing operating range and speed, especially under water; decreasing diving time, and prolongation of submergence. These problems were studied between wars, as were those of specialization and rescue. By World War II, the United States submarine fleet ranged from small coastal types of 200-400 tons surface displacement to the giant *Argonaut* (minelayer), *Narwhal,* and *Nautilus,* which were of more than 2,700 tons. Surface speeds provided by diesel engines were 14-21 knots; submerged speeds, from electric propulsion, 8-11.

*Rescue Devices.* Ever since man first submerged in a submarine, its sinking has been a virtual death-warrant for her crew. In the 1920's, every man died who went to the bottom with the American submarines S-51 and S-4, and, as a result, the U.S. Navy put heavy stress on developing rescue devices. Two were ultimately adopted as standard equipment. For wrecks at shallow and medium depths, all American submarines are equipped with the Momsen Lung, an individual oxygen-breathing device which men could wear while leaving the sunken submarine's escape-hatch and ascending a lifeline to a surface buoy. For rescue at greater depth, the McCann Rescue Chamber was adopted.

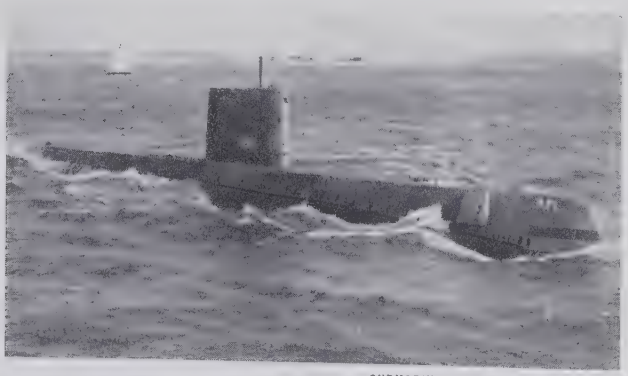
Although World War II was fought with conventional submarines, it was the incubator for radical new developments, many of which had scarcely begun to take form by V-J Day. The two most successful submarine fleets, the German and the American, were strikingly different in many respects. The American was built around the fleet-type submarine, a relatively large boat developed between wars. It was capable of patrols of two or three months during which, in the absence of effective enemy countermeasures, much time was spent on the surface.

*The Snorkel.* The German boat, on the average, was smaller. It was a stripped-down fighting machine with a minimum of crew comforts, designed for shorter forays, and compelled by concentrated and ever-deadlier opposition to spend as much time as possible under water. This need of maximum concealment led to the development of the snorkel, which could be raised to periscope height for taking in and exhausting air while the submarine was running underwater. The snorkel's primary object was to furnish the large and steady flow of air needed to permit underwater operation of the diesel engines and also to dispose of their exhaust. It thus removed an increasingly hazardous limitation under which combat submarines had labored since diesels were adopted: the need of surfacing to recharge the batteries. This required operation of the diesels which, heretofore, had been useless under water. Another purpose of

the snorkel was to augment the air supplied to the crew for breathing.

*The Midget Submarine.* Another distinctive development of the period was the midget submarine which all major navies used in one or more forms. The simplest type was the British "chariot," a submersible propulsion unit little more than a torpedo with a detachable warhead. Two frogmen rode astride the chariot. One operated the controls; the other cut submarine nets; together, they attached the explosive warhead by clips to the keel of the target. Slightly larger midgets, carrying crews of two or four men, were submarines in miniature. They were designed to slip into harbors or shallow waters on special missions, as in the Japanese attack on Pearl Harbor. Midgets, of course, operated at short range and had to be transported within striking distance by surface ships or mother submarines.

By 1943, the Allies had developed such effective counter-submarine measures that it was unsafe for German U-boats to surface at all. Even snorkel or periscope could be picked up on radar. Hence, late in the war, the Germans concentrated on developing radically new submarines which could be submerged longer and deeper, and which had increased underwater speed and quieter mechanical operation. "Type XXI" was to be a streamlined U-boat with enormously increased battery power to reverse the normal ratio of submerged to surface speed and with great pressure resistance for greater depth. "Type XXVI" was to be more streamlined, even to the elimination of deck guns and most of the conning tower and equipped with four alternative propulsion units. The chief of these, the Walther cycle turbine, was to drive her at an underwater speed of 25 knots and to permit continuous submerged operation. This turbine derived its energy from combustion of diesel fuel in decomposed hydrogen peroxide. Neither type submarine had been placed in service by the end of the war, but they are evidence that German submarine research was directed toward the problem no submarine scientist had yet solved—how to make a submersible truly a submarine; how to achieve a vessel with unlimited capacity to remain and maneuver under water. Whether the Germans would have achieved that end is still largely a military secret of the countries which conquered Germany at a time when these submarines were about ready for a practical trial. It is reported that the Germans' unfinished task was carried on by the Allies and that Great Britain has installed a version of the Walther turbine in two submarines, the *Excalibur* and *Explorer.*



SUBMARINE LIBRARY, GROTON, CONN.

*THE FIRST ATOMIC POWERED SUBMARINE, THE U.S.S.* NAUTILUS

*Atomic Submarines.* The utilization of atomic energy became a reality with the launching, trials, and acceptance by the U.S. Navy of the *Nautilus,* the latest of the real and fanciful submarines to bear that favorite name. The *Nautilus* is an improvement on previous submarines in almost all respects. She is revolutionary in one. That one, of course, is her engine. More specifically, it is the heat source or power plant, the engine itself being simply a high-speed turbine driving the propeller shafts through reduction gears. The *Nautilus,* like Holland's *Plunger* and the Nordenfeldt-Garrett boats, is a steam vessel.

The steam submarine of earlier decades was defeated by the absence, under water, of an adequate air supply for combustion and of a feasible vent for exhaust gases. The combustion chamber of the Nautilus requires neither air nor exhaust. It is an atomic pile, heavily shielded to protect the occupants of the vessel. The tremendous heat generated by the fission of uranium atoms in the reactor is communicated to specially and continuously purified water pumped through it under such extreme pressure in a sealed system of pipes that the water will not turn to steam. This heated water passes into a heat-exchanger, where it turns the water of a separate sealed system into high-pressure steam. The last rotates the turbine, as it does in any modern marine steam propulsion unit.

The atomic power plant and its capacities tinge and modify everything else about the *Nautilus.* Her hull is typical of submarines as to components, but it lacks the sharp cutwater of previous boats. The *Nautilus* is fully streamlined for underwater cruising; deck projections are eliminated. She is designed to withstand enormous pressures—all that has been revealed officially is that she will outdive any predecessor. The *Nautilus* also realizes one of the earliest dreams of submarine theorists. She runs faster submerged than surfaced, having an underwater speed of more than 20 knots. Highly specialized electronic equipment enables her to find her way beneath the surface, to perceive and distinguish friendly and unfriendly vessels, and even to join combat with enemy submarines under water. For protracted submerged patrols, she is also much more comfortably arranged and equipped than any forerunner. She is large—about 3,000 tons displacement—and her economies, especially in the matter of fuel tanks, allow the crew much more generous air-conditioned living space than was possible on earlier boats.

The *Seawolf,* a companion to the *Nautilus,* is understood to differ from the *Nautilus* chiefly in that the coolant fluid which transmits the heat of fission to her heat-exchanger is liquid sodium instead of water. With these two craft, the submarine has caught up to the imagination of Jules Verne.

C. B. M.

**SUBMARINE RESCUE CHAMBER,** a contrivance for rescuing personnel from a submerged submarine. It is a steel structure, 10 ft. high and weighing about nine tons. Its maximum external diameter is 7¾ ft. and it tapers downward to a base diameter of 5 ft. It is open at the bottom, and around the bottom edge is a rubber gasket which serves to make a watertight seal between the chamber and a machined apron that surrounds each escape hatch at the deck level of the submarine. Every submarine in service has two of these hatches, one at each end of the ship.

The chamber is capable of withstanding an exterior pressure equivalent to the submergence crushing depth of any U.S. Navy submarine. Internally, the rescue chamber is subdivided into a large upper compartment, in which all control apparatus is housed, and a lower, smaller compartment which is surrounded by a single ballast tank. Between the upper and lower compartments is a hatch which can

only be opened from the inside. The capacity of the ballast tank and of the lower compartment is the same, either taking 4,000 lb. of salt water to fill it.

Outside on the top of the chamber are four watertight fittings. One serves as a connection for the 1-in. wire-wound hose that delivers compressed air from the tending vessel, and another is a connection for the 1¼-in. wire-wound hose that carries back to the surface craft all air vented from within the rescue chamber and the exhaust of the chamber's air motor. The third fitting is a connection for the telephone circuit, and the fourth connects the cable that carries current for the electric lights in the two compartments. By turning on the light in the lower compartment, an operator in the upper one can peer through an eyeport in the floor and see if all is clear. In addition to these four fittings, there is a large external pad eye for hoisting the chamber in and out of the water; when the chamber is being operated a ¾-in. wire is made fast to it and is called the backhaul wire.

**Upper Compartment.** The upper compartment holds the operators and passengers. In this compartment are: the operating motor with its air supply, exhaust lines, etc.; the blow and vent manifold for the lower compartment, and ballast tank. The water manifold for flooding and emptying the lower compartment and ballast tank, a hose connection for filling the 14 movable adjusting tanks, plus gauges, lighting system, telephone, four holding-down bolts, etc., are also therein. Three eyeports are fitted into the sides of the hull of this compartment, and, in addition, there is one eyeport in the floor to see into the lower compartment.

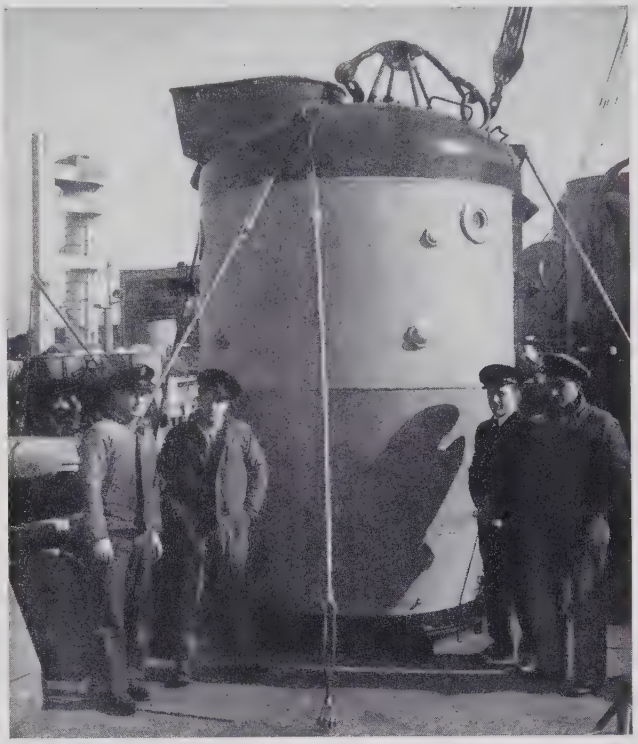
**Lower Compartment.** The lower compartment contains the downhaul cable and reel, a sheeve through which the wire runs, and a bracket which serves as a fair lead for the wire that centers it in the compartment when hauling in or paying out. This cable is of 7/16-in. plow steel wire. One end is secured to the reel, and to the other end a special shackle is made fast to fit the bail of a submarine hatch. The sheeve and bracket can both be swung back out of the way after the cable has been unfastened from the submarine hatch to allow this hatch to open and to provide necessary room for the passengers to enter the chamber.

In a circular web running around the inside of the hull in this compartment are a number of slots spaced at equal intervals. The threaded ends of the holding-down rods, stored in the upper compartment, fit into these slots; the other end hooks into the pad eyes around the outside of the submarine hatch to hold the chamber on the submarine.

**Ballast Tank.** The ballast tank is a closed annular compartment in the hull of the rescue chamber which runs completely around the lower compartment. Access to this tank is through handholes from the lower compartment. In the bottom of this tank is the permanent lead ballast which is used initially to compensate the chamber when it is put in service, and the weights are so positioned that the chamber floats level in the water instead of listing toward the side that the motor and reel are on. This lead ballast is kept from shifting by the internal vertical ribs inside of the ballast tank, so that if the chamber should be placed on its side these weights would not fall down to the low side.

## OPERATION

Before the chamber can be used for rescue, it must be assumed that the sunken submarine has been located and that a submarine rescue vessel or a similar craft is moored over the wreck. Enough wire must then be run off the reel of the chamber on to the deck of the surface vessel to reach the bottomed submarine, with some slack left over. A diver then takes the end of this wire down with him and connects it to the bail of the submarine hatch, inspects the hatch to ensure it is clear of debris, and returns to the surface. As soon as the diver is clear, the rescue chamber, with its five attachments (supply hose, vent hose, telephone cable, light cable, and ¾-in. backhaul wire), is lowered over the side with two operators, usually divers, where it floats alongside of the tending vessel. The operators then fill the fourteen movable adjustable tanks, which hold 67 lb. of water each, giving the chamber a weight load of nine persons. The



U.S. NAVY PHOTO

*SUBMARINE RESCUE CHAMBER ON DECK OF RESCUE VESSEL*

chamber with nine persons in it has a positive buoyancy of approximately 1,000 lb.; these tanks are filled to make the chamber heavier and relieve the motor of extra work on the descent. All entrapped air is then vented from the top of the lower compartment allowing this space to become full of water. The chamber is now ready for its descent.

When the operators start the air motor, the cable winds on the reel, and the chamber is pulled down toward the submarine against its own positive buoyancy. During this descent, the air motor is exhausting into the vent host and the chamber operators are riding in a space that is under atmospheric pressure, no matter how deep the chamber goes—unless special work requires the chamber to be operated virtually as a diving bell.

The chamber usually descends at a rate of about 20 ft. per min., and the operators, by reading a gauge in the side of the chamber, can determine their depth as they would in a submarine which is operating submerged. The motor is so designed that it will stall before it can put a breaking strain on any part of the apparatus. When the bottom of the chamber strikes the submarine hatch seat, or, if the visibility is such that the hatch can be seen through the eyeport, when the hatch comes into sight, the motor is slowed down and is allowed to draw the chamber down as tightly as possible against the seat. When the submarine is listed to one side on

the bottom, it may require some maneuvering to get the chamber against the seat and especially to get it reasonably well centered over the hatch; however, it is not impossible at any angle at which the submarine is likely to lie.

With the chamber on the seat, the ballast tank is now flooded. While this tank is being flooded, a heavy strain is maintained on the downhaul cable to take in any slack that might result from this operation. As this compartment is flooded, the chamber goes from a positive to a negative buoyancy. As soon as this tank is full of water, the lower compartment is blown dry of water by blowing it out either under the gasket or through the water manifold. The chamber operators can tell when this compartment is dry because the chamber shudders as the air rumbles out from under the gasket, and they can also see the air bubbles rise past the ports on their way surfaceward. The air is now shut off and the vent to the lower compartment is opened wide, allowing the air pressure to come into the upper compartment and out through the vent hose to the surface.

As the lower compartment vents, the sea pressure seals the chamber tight against the seat. During the venting, the operators determine if a seal is made by looking through the eyeport into the lower compartment. If a seal is made, the lower compartment fills with vapor. If the compartment fills with water instead of vapor, the attempt has been unsuccessful, and it will be necessary to blow the lower compartment and try again. When a seal has been made, the lower hatch is opened. One man drops into the lower compartment and fastens the four holding bolts tying the chamber to the submarine. When they are secured, the cable is slacked off and the guide bracket is swung to one side. The submarine hatch is now opened and personnel enter the chamber. A total of six to seven average-sized men may be taken aboard the chamber, without reducing the reserve buoyancy below 1,000 lb., by emptying all the adjustable ballast tanks that are stored in the upper compartment.

When no more than seven passengers are in the chamber, the submarine hatch is closed. The fairlead bracket is swung back to the center, re-rigged, and a strain is again placed on the downhaul cable. The four holding-down bolts are removed and passed up into the upper compartment. The adjustable ballast tanks are dumped into the lower compartment on to the submarine hatch. The lower chamber hatch is closed and the lower compartment is flooded from the sea. The ballast tank is now blown and the buoyancy breaks the seal. The motor is now operated to pay out the cable on the reel and the chamber floats surfaceward. On reaching the surface, the chamber is floated over to the side of the tending vessel where the passengers disembark and the chamber is ready to commence another trip.

In order to carry more than seven passengers, no tanks are dumped, and the chamber rises to the surface with the lower compartment empty; as many passengers as the upper compartment will hold, in addition to the crew, may then be carried. In October 1947, a rescue chamber from the submarine rescue vessel *U.S.S. Tringa* removed 16 passengers from the submarine *Corsair;* with the two operators, 18 persons were in the chamber during a test exercise.

Once a trip has been made, the chamber can make another very quickly, and it is easier to control the chamber with its normal reserve buoyancy of 1,000 lb. than with the much larger buoyancy which will result from the lower compartment being empty even with the upper compartment full of passengers.

During September 1948, final tests were completed on a downhaul, wire-messenger buoy. With this device, it is no longer necessary for a diver to connect the downhaul wire before the chamber can be used. Two of these buoys are fitted into the deck of each submarine, one on the bow and one in the stern, with one end of the downhaul wire made fast to the submarine hatch bail and the other to the buoy.

When released by the submarine, the reel pays out wire until the buoy surfaces. Then it locks so that no extra cable is allowed to pay out and become fouled on some portion of the submarine. Upon the arrival of the rescue vessel, the wire is transferred from the buoy to the rescue chamber. Rescue is possible at depths greater than a diver may be able to go. P. C. C.

**SUBORDINATION,** in sentence structure, the employment of subordinate clauses with independent clauses to indicate the relation of the ideas expressed in these clauses. It is contrasted with co-ordination, in which all clauses are independent and all the ideas expressed in them are accordingly presented, at least formally, as of equal importance.

By co-ordination it is always possible to express a meaning that is usually conveyed by the use of subordinate clauses. Examples of such co-ordination are frequent in Latin, especially in early writings; a characteristic one is Plautus' *filiolam ego unam habui, eam unam perdidi* ("I had one little daughter, I have lost that one"). Constructions of this kind are more frequent in English than in other modern languages, familiar examples being *obey my voice, and go fetch me them* (Genesis xxvii:13); *you should try and be reasonable; hurry up, it is getting late;* and *let him talk, it will do no harm.*

Co-ordination corresponds to a more primitive, simple, and direct approach to expression, whereas subordination reflects a greater logical capacity, a tendency to organize concepts hierarchically, to deduce consequences from causes, to connect different thoughts and facts into a complex architectural whole. Subordination expresses ideas with more precision and clarity than co-ordination and is the mark of a more rational and philosophical culture. Plato, Demosthenes, and Isocrates employed subordination much more than Homer; Cicero and Tacitus employed it much more than Plautus. With the decay of Latin culture, co-ordination again took the upper hand, and it predominated in the early documents of the Romance peoples until the culture of the Italian Renaissance again brought subordination to the fore. As is natural, co-ordination is preferred in the simple, colloquial speech of every day and in the literature that approaches it, in all times and among all peoples. Even Cicero employed co-ordination in his rather simple and colloquial philosophical writings, and still more in his letters, whereas in his carefully prepared and highly artificial orations subordination reaches its peak. Writers of satire and epigram, the literary genres that are nearest to the spoken language, definitely prefer co-ordination, as do rather colloquial poets like Propertius and Ovid. The early Christian writers, in their enormous and successful effort to reach the masses, virtually abandoned Classical subordination, especially in their sermons and their vivacious polemical writings. Popular authors like Chiron used co-ordination amply, and so, merely as an imitation of Old Latin, did the archaists.

While subordination gives a calm, thoughtful, and somewhat pale and sedate tone to language, co-ordination is more colorful, forceful, and dramatic. It is not surprising, therefore, that English, a rather simple, energetic, and direct language, manifests a strong tendency toward co-ordination. Modern languages in general, however, with the possible exception of German, show more co-ordination than Latin

and Greek, perhaps because many Classical authors had an artificial refinement that is seldom found in modern times.

Another reason why the written language uses more subordination than the spoken one is that co-ordination depends largely on gesture and on the pauses and intonations of the speaker's voice; these elements do not appear in writing, where consequently other characteristics distinguishing subordinate from co-ordinate clauses become necessary. Most important of these are the subordinative conjunctions.

While Proto-Indo-European had no subordinate clauses, it is certain that some, though not many, were in use in Indo-European in the last stage before the separation, and that they were clearly distinguished from the independent clauses. *See also* CLAUSE; CONJUNCTION. G. B.

**SUBOTICA** or **SUBOTITSA** [su′botitsɑ], a large agricultural, manufacturing, and trading town in Voivodina, Yugoslavia, about 100 mi. northwest of Belgrade and less than 10 mi. from the Hungarian border. A royal free city in Hungary, it was incorporated into Yugoslavia in 1918. Manufactures include mainly textiles, shoes, iron furniture, and railway equipment. Pop., 1948, 112,551. S. Van V.

**SUBSTANCE,** literally, that which stands under or supports the qualities and relations we directly observe.

"Substance" is a philosophical concept developed from certain common-sense convictions about the world, of which the three following have played important roles historically in determining the concept. (1) Sets of qualities and relations that cling together in perceptual experience have some matrix binding them together. Thus an apple is thought to be more than redness, sweetness, and sphericity: it includes a stuff or material uniting these properties into a single thing. (2) Observable changes are never complete changes. There is always something that persists, that is subject to change only in its properties, never in its inner being. Thus change is not a series of discrete and unconnected states, but a history of some persisting thing. Furthermore, this persisting something is continuous in existence between any two times in which it exists: it contains no gaps in its history. It is a single apple that ripens from green to red, not a series of apples. (3) Concrete existing things are more than sets of universals. The redness of the apple is not redness in the abstract; it is a concrete case of redness. The apple is not its properties; it has or exemplifies them. It is an existing individual characterized by properties, which are (or could be) also exemplified by other individual things.

These convictions of common sense, innocent as they seem, have given rise to serious problems in the philosophy of substance. One source of these problems is the confusion of the three convictions with one another. Though analogous, they are not identical, and when one concept is made to cover all, clarity is not achieved. Besides this, in each of these convictions, common sense goes beyond what is directly observed. Hence, in criticizing the common notions of substance, philosophers have often denied one or more of them.

Aristotle, the great philosopher of common sense, attempted to include all three convictions in his notion of substance. According to him, primary matter is a matrix binding "forms" (properties) together; it remains unchanged whatever forms are added or withdrawn; and it is the principle of individuation.

Plato had held a view of substance that was far more radical from the standpoint of common sense. Since he held that forms (qualities and relations) are substantial in their own right, he denied the third conviction of common sense listed above, arguing that individuals cannot really be known, but only universals. It may be questioned whether he did not deny the first conviction, for he thought that the unities of perceptual things are illusory. However, persistence despite the appearance of change was retained by Plato, although placed in universals (forms) rather than individuals.

The positivists—such as David Hume, J. S. Mill, Ernst Mach—have accepted the third of these convictions without the others. Their rejection of the first two has been on the ground that a unifying matrix and a persisting substratum are unobservable. Thus the individuals they accept are not unified and persisting physical things, but transient sense occurrences.

Alfred North Whitehead has developed a philosophy of events that retains the first common-sense conviction, but essentially denies the second and perhaps the third. The matrix uniting properties into an event is simply a temporal togetherness, an arising into the same unity of time.

In each of these cases there has been a tendency to push substance out of experience or to deny that it can be clearly known. But each philosophy has retained at least one of the basic common-sense convictions and it is worth noting that in each of these convictions common sense goes beyond what is directly perceived. Even extreme empiricists make of ongoing experience or perceiving a principle of individuation which cannot itself be perceived. The notion of substance is more than an empirical idea. E. W. H.

**SUBSTRATUM, SUPERSTRATUM, ADSTRATUM** [sʌbstre′təm, supərstre′təm, ædstre′təm], terms used in linguistic science to characterize languages which exert or have exerted some formative influence on other languages. Where the terms *substratum* and *superstratum* apply, the occasion for such influence is the invasion of one language's territory by speakers of another language; where the term *adstratum* applies, the languages concerned occupy territories that have a common frontier. When a linguistic territory is invaded, either by conquest or penetration, the superposed language of the invaders may or may not become predominant over the language of the territory. If the new language becomes predominant, the old language is known as the *substratum* of the new. If the old language persists and the superposed language is not adopted, the superposed language is known as the *superstratum* of the old language.

The three concepts were developed chiefly through the work of M. Bartoli, W. von Wartburg, and R. Jakobson in the twentieth century, but the idea of the substratum was first advanced as early as 1846, by G. I. Ascoli. By attributing to the conquered Celtic population of transalpine and cisalpine Gaul the change of Latin *ū* to *ü* in French, Provençal, Piedmontese, Lombard, and other languages, Ascoli showed that Celtic bore toward Latin what would now be called the relation of substratum. Latin has a number of other substrata, including Etruscan, Osco-Umbrian, Messapic, and Venetic, and it may be shown, among countless other examples, that English has a Celtic substratum, Russian a Finnish substratum, and Spanish an Iberian or Basque substratum, or perhaps both of these substrata.

Examples of superstrata are also abundant. Thus, in France the superstratum is Frankish; in Italy it is first Gothic, then Lombard, then Frankish; in Spain it is Visigothic and then Arabic; in Russia it is Scandinavian and then Tatar; in Greece it is Turkish and Venetian.

The adstratum is well exemplified in Germany. Although the Germans were never conquered in their great bulk by the Romans, their language was deeply affected by contact

with the Gallo-Romans in the Rhine valley. Through this contact, without any general transfer of population, the Germans received many cultural words (e.g., *Kirsche, Wein, Keller, Kalk, Essig, Kaiser,* etc.) and important grammatical and stylistic innovations of many kinds (e.g., Fr. *le chien* = Ger. *der Hund, un chien* = *ein Hund, j'ai vu* = *ich habe gesehen, il est allé* = *er ist gegangen, il a été tué* = *er ist getötet worden, je verrai* = *ich werde sehen,* etc.).

The respective importance of the three elements that these terms denote varies everywhere according to historical conditions. Thus, the importance of the Celtic substratum seems to be small in England, whereas it is rather strong in France; the part played by the Visigothic superstratum is almost insignificant in Spain, whereas the Arabic superstratum in Spain and the Frankish superstratum in northern France had an essential role in shaping the new languages. On the other hand, if the Norman-French superstratum had been a little stronger, or had received a few more reinforcements from France, English would now be a Romance language and Anglo-Saxon would be reduced, like Celtic in France, to the position of substratum.

It is sometimes difficult to distinguish between substratum, adstratum, and superstratum. For example, there is hardly any doubt that Basque has influenced Spanish, but it is not certain whether Basque is in this instance an adstratum or a substratum; similarly, Bulgarian has been influenced by Greek, and Romanian by Slavic, but it is uncertain whether these are examples of adstratum or superstratum. The problem, in any case, concerns history rather than linguistics, the distinction between substratum, superstratum, and substratum being an empirical one. The three terms offer a convenient device to indicate certain series of linguistic phenomena, but they do not cover all the manifold interferences and reciprocal influences that affect languages, for these are as changing and as complicated as life itself. G. B.

**SUBWAYS, ELECTRIC,** rapid-transit railways for passenger service located beneath the surface, usually under city streets. They may be as close to the surface as construction conditions will permit, or may be as much deeper as is considered desirable.

Subways have been in use for many years. Construction on the earliest line, part of the London Underground, began in 1853. The system was originally operated by steam; conversion to electricity was accomplished in 1891. Other lines were added to the system from time to time. In the United States, the first subway was opened in Boston in 1898 and the second in New York in 1904. Both systems have been extended several times. Elevated railways, an older form of rapid transit, fell into disrepute on account of the noise and the obstruction to light and air along the routes, so that in New York and Boston a portion of them were abandoned and replaced with subways. From an operating standpoint there is little difference, and some of the routes include both, subways serving the more congested sections.

Subways and elevated railways have private right of way, with no interference from street traffic. Passenger stops are usually much less frequent than on surface lines, being spaced from ¼ to ½ mi. apart for local trains and 1 to 3 mi. for expresses. In nearly all instances, stations are of the prepayment type in which the passenger pays before entering the loading platform enclosure. These arrangements permit higher operating speeds, larger cars, and trains made up of many cars. With these advantages, rapid-transit lines are able to move far more passengers at scheduled speeds up to double those of surface lines, and at low unit operating cost.

The disadvantage of subways and of rapid-transit lines, in general, is almost entirely the high cost of construction, which may be as much as $1,000,000 per mile of track. The expense usually must be borne by the municipality, as the carrying charges on the investment are so much higher than those for surface transportation that it is seldom possible for a private operator to assume the burden. Only four cities in the United States—New York, Boston, Philadelphia, and Chicago—have subway lines of any extent, and in each of these the public authorities have done all, or most, of the financing.

**Control and Power.** American rapid-transit systems and most foreign systems are operated by 600-volt direct current with trains of two to ten cars, all, or a part, of which are equipped with motors. Power is controlled from the motorman's position in a cab at the front end of the leading car by the multiple-unit control system, small currents in the master circuit actuating the main motor controllers on the various cars so that each does its own share in driving the train. Air brakes, likewise, are controlled from the motorman's valve by electric or pneumatic means, or by a combination of the two.

Power is almost always supplied from a.-c. lines, often those of the local utility. It is converted to direct current at the proper voltage in substations by synchronous converters or mercury-arc rectifiers, the latter being favored in later installations on account of their high efficiency and ease of automatic operation. The substations are spaced according to the power demand in order to maintain voltage as nearly uniform as possible throughout the system.

Since subways are on a private right of way, it is not necessary to keep the contact line out of possible reach. Only employees are allowed to approach the tracks, and they are trained to avoid live electric circuits. Accordingly, all American subways and most foreign ones are equipped with the third-rail system, in which a steel rail, supported on insulators alongside the track, supplies the current. Although the electrical resistance of steel is about seven times as much as that of copper, it is much cheaper and, with the method of support, the cross section can be as large as desirable. The contact surface is rigid and maintenance costs are low. Where the largest rail has insufficient conductivity to carry the current, it is supplemented with copper feeders. Contact with the third rail is made by shoes mounted on the trucks of the motor cars. Thus, there are many contacts in parallel, making it easier to collect the large currents required when starting, which in some instances run as high as 10,000 amp. per train. The multiplicity of contacts also gives continuity of power where the third rail is discontinuous, as at crossings or junctions.

**SUCKER,** a name given to any of numerous fresh-water fishes of the family Catostomidae, closely related to the carp. They have a suckerlike mouth with soft, thick lips. All species are found in North America except two which are native to Asia. Suckers are found near the bottom of streams and lakes feeding on aquatic plants and animals. Their flesh is poor but extensively eaten. The white sucker, *Catostomus commersoni,* native to streams east of the Rockies, attains a

length of 18 in. Buffalo fishes, the black horse, and the red horse are among the most important species belonging to this family. *See also* Buffalo Fish; Red Horse. C. R. Eb.

**SUCKLING, SIR JOHN** (1609-1642), English poet, was born in Twickenham, near London, and baptized Feb. 10, 1609. After attending Trinity College, Cambridge, he entered Gray's Inn. Inheriting a large fortune from his father, he traveled extensively in Italy and France; on his return to England in 1630, he was knighted. With the Marquis of Hamilton he fought under Gustavus Adolphus, taking part in several important battles. He returned to England in 1632 and became a well-known figure at court, where he was admired for his wit and his wealth. Suckling entertained extravagantly and often put on lavish performances of his own plays. In 1641 he had an active part in a plot to gain control of the army for the King. Upon being discovered he fled to France, where, according to John Aubrey, he committed suicide in May or June 1642.

Many of Suckling's works were gathered together in *Fragmenta Aurea* (1646), which contained his graceful *Ballad Upon a Wedding. A Session of the Poets* (1637) comments satirically on Ben Jonson, D'Avenant, Carew, and other contemporary writers. Suckling's lyric, *Why so pale and wan, fond lover,* first appeared in his play, *Aglaura* (1637). His other plays, *The Goblins* (1638) and *Brennoralt, or the Discontented Colonel,* are also marked by fine lyrics, some of which were set to music by Henry Lawes. Unlike many writers of lyrical and occasional verse in his day, Suckling did not fall under the spell of Ben Jonson's poetry, but rather was an admirer of John Donne.

R. C. B.

**SUCRE, ANTONIO JOSÉ DE** [su'kre] (1795-1830), South American military officer and liberator, was born at Cumaná, Venezuela, Feb. 3, 1795. He began a military career early in life and at the age of sixteen was a colonel in the insurrectionary army. In 1822, acting as Simón Bolívar's agent with the rank of general, he defeated the Spanish forces at the Battle of Pichincha, thus causing the capitulation of Quito. In August 1824 Sucre routed the Spaniards at Junín in Peru, and three months later he defeated the combined Spanish forces in the famous Battle of Ayacucho. He followed up his victory by liberating all of upper Peru from Spain and by proclaiming the territory a new republic with the name Bolivia. Supreme authority over the new state was vested in Bolívar, who transferred his powers to Sucre. Although he attempted to resign, Sucre was elected first president of Bolivia in 1826. After two years, native discontent with a foreign president caused the beginnings of insurrection, and in 1828 Sucre resigned, withdrew from public affairs, and attempted a quiet life at Quito. He emerged from retirement in 1830 to act as president of a congress formed by Bolívar to insure Colombian unity. The project was not successful, and during his return to Quito on June 4, 1830, Sucre was assassinated near Pasto in Colombia. Sucre ranks today as one of the great liberators in the wars fought for independence in the northern states of South America. S. G. I.

**SUCRE,** the legal capital of Bolivia, 240 mi. southeast of La Paz on the Río Quirpinchaca, at an altitude of 8,532 ft. The city was founded as Chuquisaca by Pedro de Anzurez de Campo Redondo on Sept. 29, 1538. The name was finally changed to Sucre in honor of Antonio José de Sucre. During the Colonial period, it was the seat of the *audiencia* of Charcas. Among the famous buildings is the Basilica Metropolitana, built in the seventeenth century, which was damaged by the earthquake that destroyed much of the city in 1948. The University of St. Francis Xavier was founded in 1624. A railway connects Sucre with Potosí, 50 mi. southwest, and local air lines provide service to La Paz, Potosí, and all major cities. Pop. 1950, 40,128. S. G. I.

**SUCROSE.** *See* Sugar Chemistry.
**SUCTORIA.** *See* Animal Systematics; Protozoa.
**SUDAN.** *See* Anglo-Egyptian Sudan; French Sudan.

**SUDAN GRASS,** a sorghumlike annual, *Sorghum vulgare* var. *sudanense,* tall and slender, bearing very numerous leaves about ½ in. wide. The flowering panicle is conspicuous, being composed of many brownish spikelets, and is about a foot in length. The whole plant reaches a height of 6 to 10 ft., and closely resembles Johnson grass. It is widely cultivated for hay in the semiarid regions of Africa, where it is native, and in the extreme southern part of the United States where it is planted, to some extent, for forage.

J. C. Wis.

**SUDANIC.** *See* African Peoples.

**SUDBURY,** a city and the county town of the district of Sudbury, Ontario, Canada, about 300 mi. northwest of Toronto on Provincial Highways 17 and 69. It is served by the Canadian National and Canadian Pacific railways. Near-by Lake Ramsay has an airplane base used for general charter service for forest fire protection. Sudbury was founded in 1883 during the building of the Canadian Pacific Railway; it was incorporated as a town in 1892, and as a city in 1930. The region produces over eighty-five per cent of the world's nickel as well as important quantities of copper, gold, silver, lead, and platinum. Neither mines nor smelters are within the city limits. The city is a residential, commercial, and distributing center. It has a mining and technical school, a business college, and a college for general instruction. Pop. 1951, 42,410. D. F. P.

**SUDDEN SAWLOG,** a variety of poplar grown for quick shade and soft timber, especially in the northern parts

of the Great Plains region. It is remarkable for its vigorous, rapid growth and great hardiness; within seven years after planting by cuttings, it attains a height of 50 to 60 ft. and a trunk diameter of 8 in. The sudden sawlog is probably of Siberian origin, and is thought to be a form of the cottonwood, *Populus deltoides missouriensis,* or a hybrid from it. It is being grown experimentally as a possible source of pulpwood. J. C. Wis.

**SUDERMANN, HERMANN** [zu'dərmɑn] (1857-1928), German dramatist and novelist, was born at Matziken, in East Prussia, Sept. 30, 1857. As a youth he was apprenticed to a chemist, but was later able to study at Tilsit and Königsberg. In 1877 he moved to Berlin, where he resided the rest of his life, except for the year 1894, which he spent in Dresden. Sudermann died in Berlin on Nov. 21, 1928.

A very prolific writer of both fiction and drama, Sudermann attained a high reputation in both fields. The central intention of his novels lies in the portrayal of the life and development of individuals as distinct personalities; such social problems as form backgrounds to the stories are not the author's chief concern. On the other hand, his most important dramas are social satires, in which the characters are typical conflicting persons of recognizable strata of society.

Sudermann began his literary career as a journalist, and a journalistic vein runs through all his works, evidenced in lurid effects, sharp contrasts, and strong emotions; these, even when extreme, appealed to popular taste. He portrays the vagaries of people and society as he found them; therefore the utterances of his characters do not necessarily represent his own views nor justify the charge of inconsistency in his own philosophy of life.

Sudermann's first novel, *Frau Sorge* (1887) ("Dame Care") has remained his most popular work of fiction; next in popularity is *Der Katzensteg* (1890) ("The Cat's Bridge"; translated into English with the title *Regina*). His first drama, *Die Ehre* (1890) ("Honor"), created a great public sensation and brought him fame. Undaunted by the failure of *Sodoms Ende* (1891) ("Sodom's End," translated into English with the title, *The Man and His Picture*), Sudermann produced *Heimat* (1893) ("Home"; translated into English with the title *Magda*), his most successful play.

With the exception of two novels, *Iolanthes Hochzeit* (1892) ("Iolanthe's Wedding") and *Es war* (1894) (*The Undying Past*), Sudermann devoted himself exclusively to the stage until 1908. He produced nine dramas and seven one-act plays during this period, the most important of which are: *Das Glück im Winkel* (1895) ("The Vale of Content"), *Johannes* (1898) ("John the Baptist"), *Die drei Reiherfedern* (1899) ("The Three Heron's Feathers"), *Johannisfeuer* (1900) ("St. John's Fire"), and *Es lebe das Leben* (1912) ("The Joy of Living").

Little can be said for the novels and plays written by Sudermann in his declining years. His outstanding novel of the period is the voluminous and disreputable *Das hohe Lied* (1908) ("The Song of Songs"), which enjoyed considerable popularity in its day. Very creditable, however, are the sketches published as *Litauische Novellen* (1917) ("Lithuanian Tales"), and the charming autobiography, *Das Bilderbuch meiner Jugend* (1922) ("The Book of My Youth").

**SUDETENLAND** [zude'tənlɑnt], geographically, the mountainous northwestern portion of Bohemia and Silesia in Czechoslovakia. Politically, the term Sudetenland, common since 1910, refers to those regions along the western frontier of Czechoslovakia which had a mixed Czech and German population. Dominated by the Sudetes Mountains, the area is noted for both its ancient and picturesque towns and its modern industrial cities. Glassmaking, brewing, and armaments are among the established industries. The history of Sudetenland has been influenced by the relation of its former inhabitants, some 3,600,000 Germans, to the Czechs living with them. This problem was settled in 1945-1946 by the removal to Germany, according to principles agreed on at the Yalta Conference, of the German-speaking inhabitants by the Czechoslovakian government.

These Sudeten Germans were partly the descendants of medieval German colonists and partly of Germans established in Bohemia in modern times by the Austrian Hapsburgs. The Sudetens had a deep consciousness of their German character and carefully preserved their language, culture, and dress. Their political organization began toward the end of the nineteenth century, when the Sudeten Germans showed a marked inclination toward Pan-Germanism. Their annexation to Germany was opposed at Versailles in 1919, and the Sudeten Germans became citizens of the Czechoslovakian Republic. Friction with the Czechs developed over language, school, and autonomy issues. Pan-German sentiment in Sudetenland contributed to the success of the National Socialists (Nazis) whose local leader, Konrad Henlein, won the support of more than 60 per cent of the German-speaking population in the elections of May 19, 1935. By June 1938, the Nazis claimed 90 per cent of the Sudeten Germans. This situation was given force by the insistent backing of Germany. When the Czech government rejected Henlein's proposal that the Sudeten Germans be given autonomy and larger cultural rights, an international crisis developed—the Munich crisis—because Germany threatened armed intervention (September 1938). A settlement agreeable to Germany, France, and England was arranged at the Munich Conference on Sept. 29, 1938. The partitioning of Czechoslovakia was authorized in order that the Sudetenland might be incorporated with Germany, and by the end of October 1939 German occupation was completed. Sudetenland was restored to Czechoslovakia in 1945. W. O. S.

**SUE, MARIE JOSEPH EUGÈNE** [sü'] (1804-1857), French novelist, was born on Jan. 20, 1804, in Paris. The son of a chief surgeon in the Imperial Guard, Eugène Sue himself saw some years of medical service in the army and navy. Having inherited a fortune on the death of his father in 1829, he resigned from the service to devote himself to literature. He began writing, in the manner of James Fenimore Cooper, stories that were faithful, dramatic pictures of seafaring life: *Kernock le pirate* (1831), *Plick et Plock* (1831), *Atar-Gull* (1831), *La Salamandre* (1832), *La Coucaratcha* (1832), and *La Vigie de Koatven* (1832). He also compiled an *Historie de la marine* (1835-37). He then turned to the novel of elegant society with *Arthur* (1838), *Le Marquis de la Létorière* (1839), and *Mathilde* (1841), and essayed the historical romance with *Lautréaumont* (1837) and *Jean Cavalier* (1840). Finally, under the impulsion of a contemporary wave of interest in socialism, he composed his two most popular novels: *Les Mystères de Paris* (1842-1843) and *Le Juif errant* (1844-1845) (*The Wandering Jew*). These two *roman-feuilletons,* or serial novels, were intended by Sue to expose the defects in the social system and helped turn public opinion toward the revolutionary ideas of 1848. Though inartistic by virtue of their negligent style, loosely constructed plots, and deliberately horrifying incidents, these

novels achieved an immense popularity among the masses, for Sue had great fertility of invention and a rare talent for dramatizing the simplest situation. In 1850, Sue was elected to the Legislative Assembly; but after the *coup d'état* of Dec. 2, 1851, he went into exile in Italian Savoy, where he died on Aug. 3, 1857. R. A. P.

**SUETONIUS (GAIUS SUETONIUS TRANQUILLUS)** [swito′niəs] (c. A.D. 70-140), Roman biographer, practiced in the law courts in his earlier years and enjoyed the friendship of Pliny the Younger. Later he became an imperial secretary under Hadrian and thus gained access to official records which were of great use to him as a writer, but in 121 he was dismissed from his secretaryship, apparently because of some failure in respect to Hadrian's wife, Sabina. Of Suetonius' biographical, historical, antiquarian, scientific, and grammatical writings, his *Lives of the Caesars,* from Julius to Domitian, has come down to us; considerable portions of the *Lives of Illustrious Men* also survive, to wit, the greater part of the section on grammarians and rhetoricians, the lives of Terence and Horace, and portions of the lives of Lucan and of Pliny the Elder. Suetonius' portraits of the Caesars are crammed with anecdotes, flattering or unflattering to their subjects, but there is no sober or consistent appraisal of character, little regard for chronology, and little political insight. G. McL. H.

**SUEVI** [swi′vai], the loosely confederated German tribes of southwestern Germany in the first century B.C. After Caesar halted the advance of the Helvetians, he defeated the Suevi (58 B.C.) under their leader, Ariovistus. Thereafter they remained quietly along the upper Rhine for over a century, until they were disturbed by the extension of the Roman frontiers by the Flavian emperors. The Suevi appear later in history as the companions of the Vandals in the invasion of Spain at the beginning of the fifth century A.D. The Suevi who went to Spain lost their identity with the coming of the Visigoths, but those who remained in the Black Forest in Germany became the ancestors of the medieval Swabians. T. B. J.

**SUEZ** [suɛ′z; su′ɛz], a city and governorate in Egypt, at the Red Sea terminus of the Suez Canal, about 75 mi. east of Cairo. It is the third port of Egypt, and a starting point for pilgrims heading for Mecca. The importance of Suez grew during World War II, especially in handling imports. The city is connected directly by rail with Cairo and Ismailia on the Suez Canal. Suez has an oil refinery and a well-developed fishing industry. Pop. 1947, 107,244. S. Van V.

**SUEZ CANAL,** one of the most important artificial waterways in the world. It crosses the Isthmus of Suez (a neck of land which connects Africa with Asia), between Port Said, on the Mediterranean, and the Gulf of Suez. Separating Egypt proper from the Peninsula of Sinai, it has a total length of 104½ mi., including 4 mi. of approach channels for the harbors. It runs nearly north and south, has a width from 310 to 525 ft. on the surface, and allows the passage of vessels having a draft of 34 ft.

**Route and Description.** The canal traverses a tract of low, sandy desert, where construction was facilitated by the Great and Little Bitter Lakes, Lake Manzala, and Lake Timsah. Both of the Bitter Lakes, which are believed to have been an arm of the Red Sea in past geological times, had their surfaces below sea level, but excavation was necessary because their depth was less than that of the canal. From Port Said to El Qantara, about 24 mi., the canal

EWING GALLOWAY

*The Suez Canal near Port Said*

passes through Lake Manzala, a shallow lagoon covering about 1,000 sq. mi. The soil of the canal area was favorable for rapid and easy excavation, and, unlike the Panama Canal, no locks were required. Drinking water is brought to the area by a fresh-water canal, which starts north of Cairo, runs northeastward to Ismailia, on Lake Timsah, and then diverges into two branches. One goes northward to Port Said, the other southward to Suez and Port Taufiq. Besides Port Said, which is situated at the canal's northern end and at what was formerly the mouth of a branch of the Nile through Lake Manzala, the only towns of considerable size on the western bank are Ismailia and Suez. Population figures in 1947 were: Port Said, 177,703; Ismailia, 68,338; and Suez, 107,244. The only settlements of importance on the eastern bank are Port Fouad, a town opposite Port Said, founded in 1926 by the Suez Canal Company as a residential quarter for its employes, and El Qantara, the starting point of the railway line across Sinai to Palestine. The canal area is connected with the Nile Valley and Delta by rail lines to Cairo from Port Said, Ismailia, and Port Taufiq. A railroad also connects it with Palestine.

**Early Canals.** The idea of connecting the Mediterranean with the Red Sea dates back to the ancient Egyptians, who constructed a boat canal from the Nile to the Red Sea in about 1300 B.C., during the time of Seti and Rameses II. This canal, which was first designed to carry fresh water from the Nile to Lake Timsah, was extended to Suez in about 600 B.C., at the time of Pharaoh Necho II. It was completed a century later and part of its original construction was used for the fresh-water canal during the building of the modern Suez Canal. Abandoned in the Byzantine era after a period of maintenance by the Ptolemies, the old canal was reopened by Amr, the Arab conqueror of Egypt under the Caliph Omar. His idea was to join the Nile with the Red Sea and supply Arabia with wheat and food. The canal he sponsored was named Khalig Amir El Muminin and was abandoned after the eighth century A.D., when the route to India was by way of the Cape of Good Hope. At the close of the fifteenth century the Venetians investigated the possibilities of a canal from the Mediterranean to the Gulf of Suez. They had found that the Cape route affected their trade adversely, but the idea of the shorter Suez route was not carried out. Early in the nineteenth century the overland route to India was established across Egypt, via the Nile to Cairo, and then by camels to Suez. Later, a proposal to cut a direct canal across the isthmus to avoid the delay and expense of the land journey was declared impossi-

ble by Lepère, the French engineer commissioned by Napoleon Bonaparte to survey the project. He based his view on erroneous measurements; however, British engineers later reported the practicability of building the canal.

**Modern Canal.** In 1854, Ferdinand de Lesseps, the French engineer, succeeded in obtaining from Said Pasha, the Wali of Egypt, a concession to establish La Compagnie du Canal Maritime de Suez. This was formed in 1858, with a capital stock of 200,000,000 francs, or about $40,000,000, in 500-franc shares. De Lesseps at first met the greatest opposition from Great Britain, which, ironically, in view of its present dependence upon the canal, tried to persuade the Sultan against the project. The work on the canal was begun in April 1859, along with work on a fresh-water canal from Cairo by way of Ismailia, which was essential to the construction. By the terms of the original concession, Egypt was to receive 15 per cent of the gross receipts for ninety-nine years, after which the canal was to be handed over to the Egyptian government. Most of the early canal shares were bought by the French, Turks, and Said Pasha, who helped the company by purchasing nearly half the stock. The Khedive Ismail refused to accept the continuance of forced labor in 1863, and this led to the arbitration of Emperor Napoleon III, by which Egypt had to pay 80,000,000 francs. In 1875, Disraeli, the British Prime Minister, bought 176,602 shares for £4,000,000 from the Khedive Ismail, who was obliged to sell because of financial difficulties. After that date British interest in the Suez Canal and Egypt increased, until at present, the British own 295,026 shares out of a total of 652,932.

The canal was opened to navigation in November 1869, after great ceremonies at Port Said and Ismailia. The project had taken ten years to complete and the total cost was £29,725,000. As originally constructed, the waterway had a depth of 26.05 ft. and a bottom width of 72 ft., but, with the increase of traffic, enlargement was needed to accommodate ships drawing 34 ft. The average time of transit through the canal was decreased from three days in 1869 to 11 hr. and 20 min. in 1939. This was for vessels navigating by night as well as by day.

**Commercial Importance.** The opening of the canal in 1869 revolutionized the world shipping picture, particularly in the Mediterranean and the Indian Ocean. The distance between western Europe and India was reduced by nearly 5,000 mi., and the journey itself was shortened by fourteen days. In addition, the canal, with more traffic from south to north than from north to south, was an aid in increasing such exports from India and Australia to Europe as rice, oil seeds, tea, wheat, wool, jute, and rubber. Other effects were reduction of the prices of Far Eastern goods in Europe, encouragement for the development of steamships, and greater importance for the ports of the Mediterranean. When the canal was opened, toll for the passage was 10 francs per passenger and 10 francs per ton, but this has been reduced several times, and no toll is now levied on persons. The following table shows the number and net tonnage of the vessels that have passed through the canal, and the gross company receipts in selected years between 1870 and 1953:

| *Year* | *Vessels* | *Net Tonnage* | *Receipts in Francs* |
|---|---|---|---|
| 1870 | 488 | 436,609 | 5,159,327 |
| 1900 | 3,441 | 9,738,157 | 90,623,608 |
| 1912 | 5,373 | 28,275,120 | 134,762,199 |
| 1935 | 5,953 | 32,727,592 | 927,746,902 |
| 1939 | 5,222 | 29,265,344 | 1,491,635,891 |
| 1950 | 11,751 | 81,795,523 | 2,670,810,911 |
| 1953 | 12,731 | 92,905,439 | 2,893,243,244 |

The number of passengers, both civil and military, who went through the canal in 1940 was 98,944; in 1948, it was a record 610,951. As a result of the high tolls, the Suez Canal Co. pays high dividends to shareholders.

**Political and Strategic Importance.** The Suez Canal is owned and controlled by a commercial company, incorporated and domiciled in Egypt and subject to Egyptian laws. The canal is not fortified, but the British, according to the Anglo-Egyptian treaty in 1936, were granted the right to station troops and planes there for twenty years. This was a matter of extended controversy between the Egyptians and the British for some years, and was solved in 1954 when the British agreed to remove their troops. The canal is open to all nations and is free from blockade, according to terms of the convention of Constantinople, which was signed on Oct. 29, 1888, by Great Britain, the Austro-Hungarian Empire, France, Germany, Italy, the Netherlands, Russia, Spain, and Turkey. The freedom of passage has only theoretical value, however, for Egypt controls the approaches. Thirty-two directors of the governing board are distributed as follows: 16, French; 9, British; 1, Dutch; 5, Egyptian; 1, American. In 1948 Somerville Pinkney Tuck, American Ambassador to Egypt, resigned that post to become the first American member of the Suez Canal Board. Two additional Egyptian directors were added in 1949, 2 more were appointed in 1954, and by 1968 Egypt will be represented by 17 directors. During World War II the canal was obstructed only for short periods, but the value of the canal proper for navigation was limited chiefly to the movement of British warships between the Mediterranean and the Red Sea. This was because the Mediterranean, as a theater of war, was unsuitable for commercial traffic. While the strategic value of the canal has decreased in the present day of air warfare and guided projectiles, its importance to peacetime maritime commerce is as great as ever. S. Van V. and W. S. V.
